LIGHT-HOUSE.

LIGHT-HOUSE, in the *Marine*, is a building or watch-tower erected upon the ſea-ſhore, to ſerve as a landmark to mariners in the night, to avoid any rocks or other dangers. The light-houſe is generally a high tower, having at the top an apartment called the lantern, with windows on all ſides, to exhibit the light made within it by the flame of an open fire, or by lamps or candles. It is frequently of ſervice to navigation, to erect light-houſes upon inſulated rocks riſing from the ſea, to warn ſhips of their approach to ſuch rocks. Of this kind are the Eddyſtone rocks off Plymouth, and the Bell rock at the mouth of the Forth in Scotland. In theſe ſituations, the heavy ſwell of the ſea, when agitated by a ſtorm, ſtrikes with ſuch force againſt the building, as to require every precaution to ſecure them from being overthrown by the continued action of ſo powerful an enemy. The Eddyſtone rocks being the moſt celebrated, as well from their peculiarly expoſed ſituation, as from the great ingenuity diſplayed in the conſtruction of the light-houſes erected at different periods upon them, renders them deſerving of particular deſcription. The hiſtory of the different erections has been already given under the head of EDDYSTONE. We here intend deſcribing the conſtruction of each, which will be a ſummary of all the different kinds of light-houſes of wood or ſtone.

Mr. Winſtanley's light-houſe was begun upon the Eddyſtone rock in 1696, and was more than four years in the erection, from the many interruptions of the wind, which from ſome quarters cauſes the ſea to break over theſe rocks with ſuch violence, as to prevent the poſſibility of landing upon them, though the ſea around is very quiet. This is occaſioned by the rocks being open to the ſwell from the Great Atlantic ocean, or from the Bay of Biſcay, in all the ſouth-weſtern points of the compaſs; and is increaſed by the form and poſition of the rocks, which have a regular ſlope to the ſouth-weſt from the deep ſea to the rock upon which the houſe is erected, and which, therefore, receives the uncontrouled fury of theſe ſeas, meeting no other object to break upon, and the effect of ſo great an extent of water, cauſed by the hard S.W. winds, continues for many days, though ſucceeded by a calm, and breaks frightfully upon Eddyſtone. When there is no wind, and the ſurface of the ſea appears ſmooth, Mr. Winſtanley's light-houſe appears, from an engraved plate of it, publiſhed by himſelf, to have been a ſtone tower with 12 ſides, riſing 44 feet above the higheſt point of the rock, which is inclined ſo as to be 10 feet lower on the oppoſite ſide of the houſe. The tower was 24 feet in diameter. At the top were a baluſtrade and platform: upon this eight pillars were erected, and ſupported a dome of the ſame diameter as the tower. From the top of this aroſe a ſmaller octagonal tower, 15 feet in diameter and ſeven in height; and upon this was the lantern 10 feet in diameter, and 12 high, containing the lights. It had a gallery or balcony ſurrounding it, to give acceſs to the outſide of the windows. The whole was ſurmounted by a fanciful iron work with a vane. The entry was by a door at the bottom, which was ſolid ſtone, except the aperture for the ſtaircaſe, 12 feet in height. Above this were three floors, the loweſt being the ſtore-room, the next the ſtate-room, and the third the kitchen. Theſe occupied the height up to the level of the platform, or open gallery above-mentioned. The dome above this contained the lodging-room, and the octagon above it the attending or look-out room, immediately beneath the lantern. This edifice was, as before-mentioned, more than four years in erecting. The firſt ſummer (for it is only in this ſeaſon the rock is acceſſible) was ſpent in making 12 holes in the rock, and faſtening 12 great irons to hold the future work. In the ſecond year, a ſolid pillar 14 feet diameter, and 12 feet high, was built as a core or centre for the building. The third year the pillar was increaſed to 16 feet diameter, and all the work was raiſed, which to the vane was at that time 80 feet. The workmen lodged in the houſe ſoon after Midſummer, but were by bad weather impriſoned 11 days before a boat could relieve them. A light was exhibited on the 14th of Nov. 1698. But finding that the ſea frequently broke over the lantern, in the fourth year the whole building was encompaſſed with a new work of four feet in thickneſs, made ſolid for near 20 feet high, and the lantern was raiſed 40 feet higher than at firſt, making it 90 feet to the top of the cupola of the lantern, above which the vane roſe 22 feet. "Yet after all," Mr. Winſtanley ſays, "the ſea in ſtorms flies in appearance 100 feet above the vane, and at times doth cover half the ſide of the houſe and the lantern, as if it were under water." The joints of the additional ſtone work of the fourth year, appear to have been covered with an iron or copper hoop encompaſſing the building, to prevent the ſea waſhing out the mortar. The building withſtood the waſh of the ſea only till the year 1703, when the inventor, being at Plymouth to ſuperintend ſome repairs of the building, went off to it on ſome of his friends intimating the danger of the building, from a ſtorm which ſeemed coming on. He expreſſed a wiſh that he might be preſent in the moſt violent ſtorm which ever blew, to obſerve its effect on the ſtructure. In this he was too amply gratified, for on the 26th of November a violent ſtorm aroſe, and the next morning no veſtige of the light-houſe remained, except ſome of the irons which were faſtened in the rock, and a piece of iron chain, which was jambed faſt into a chink of the rock, and nothing was ever afterwards found. Thus periſhed the firſt light-houſe with its ingenious, but unfortunate, builder. A Weſt Indian ſhip was loſt on the rocks ſoon after the light-houſe was overthrown. This circumſtance, and the great utility of the light while exhibited, ſtimulated the Board of Trinity houſe, who had the management of the building, to erect another, and an act of parliament, of the 4th of queen Anne, was paſſed in 1706, to enable the Board of Trinity houſe to raiſe duties on ſhips to rebuild it, of which they granted a leaſe of 99 years to Capt. Lovel, as he engaged to build and maintain the houſe. In July 1706, the work was begun under the direction of Mr. John Rudyerd, who was at that time a ſilk mercer on Ludgate hill, London, but who appears to have poſſeſſed much ingenuity and mental reſource. He, like Mr. Winſtanley, publiſhed a print drawn by B. Leus, and engraved by J. Sturt, which informs us, that it was a conical fruſtum of wood, formed of 71 upright beams, united together by being bolted to circular kirbs of wood withinſide, upon which kirbs the floors were framed. It, in ſome degree, reſembled an immenſe conical caſk, but without hoops: the diameter at the baſe was 23 feet, at the top 15 feet, and its altitude, from the higheſt point of the rock to the top of the upright, was 62 feet. At the top of the building was a balcony, ſurrounded by a railing, and in the centre of the area thus formed the lantern was ſituated. It had windows on all ſides, and was of an octagonal figure, 10 feet in diameter, and 13 high, ſurmounted by a dome with a ſimple ball at top, inſtead of the fanciful iron work which ornamented the firſt edifice. Mr. Rudyerd, from principles totally different from thoſe of his predeceſſor, made his building quite plain, without the leaſt projection or ornament on which the water could act when daſhing againſt it; and he omitted no precaution of uniting all the parts together, and faſtening the whole to the rock. As the ſurface of the rock was naturally inclined, and the whole building would have had a tendency to ſlide down it, if merely placed upon it, as Mr. Winſtanley's was, Mr. Rudyerd wiſhed to reduce its ſurface into level ſteps, upon which each timber would have a horizontal bearing; but finding this to be the moſt difficult of the whole undertaking, it was imperfectly executed, only five ſteps being cut, and thoſe did not take out all the inclined ſurface; however, it was ſufficient for the purpoſe.

The building was filled up quite ſolid for 19 feet from the loweſt point of the rock, and, excepting the well for the ſtair-caſe, was ſolid to the height of 37 feet. The ſolid was formed of three beds of moor ſtone, with ſtrong floorings of timbers between each bed, to unite them with the external uprights. The lower bed contained five courſes of ſtone, and was five feet thick; the ſecond was the ſame, and the third was four feet thick, containing four courſes. The whole erection, in addition to the weight of this ſtone, which was about 280 tons, was ſecured to the rock by 36 iron cramps, part of them arranged in a circle about a foot within the external uprights, and the remainder, which were ſmaller cramps, in an interior circle three feet diſtant from the former, to hold down the floors of timber which had the ſtone beds between them. In the centre of the building a ſtrong maſt was erected, ſecured by two cramps to the rock at the bottom, and riſing above the ſolid to the height of 48 feet, being united to the framing of each floor it paſſed through, and thus forming a central axis to ſtrengthen the whole. The houſe above the ſolid contained four apartments, the lower being the ſtore room, the next the ſtate room, the third the bed chamber, and the fourth the kitchen, immediately beneath the lantern. In the manner of fixing the irons to the rock, upon the duration of which the ſecurity of the whole work depended, Mr. Rudyerd ſucceeded moſt admirably. The holes in the rock were made by drilling two holes rather diverging from each other, ſo that they would be an inch more aſunder at 15 or 16 inches depth, than on the ſurface of the rock. A third hole being drilled between theſe two, and the three being broken into one, formed a hole larger at the bottom than the top. The iron cramp was formed of two pieces, which, when laid together, were of the ſhape of the hole, but when ſeparated, one was larger at the bottom than the top, and the other ſmalleſt at the bottom; therefore the former being firſt put down into the hole, and the latter driven in by the ſide of it, wedged it faſt, and both being united by the ſame bolts which attached them to the timbers, rendered it impoſſible to draw them out. They were put in their places hot, and a quantity of melted tallow being firſt poured into the hole, when the hot irons were put down the tallow ran over on all ſides, and thus certainly filled up all cavities. A quantity of coarſe pewter, made red-hot, was now poured into the cavity round the irons, and, being a heavier fluid, diſplaced the tallow, and filled the ſpace round them completely, the tallow effectually preventing the entrance of the ſea water into the moſt minute cavities. This method is worthy of record, as it may be applied to many other uſeful purpoſes. Mr. Rudyerd, as before-mentioned, began his operations in July 1706; in July 1708, he had ſo far completed it as to exhibit a temporary light; and the whole was completed in the following year. This building had ſome repairs of its timbers in 1723, and again in 1744, when a violent ſtorm had carried away a great number of the upright timbers: but it ſhewed itſelf, in the courſe of 49 years, to be a very excellent conſtruction of its kind, and only liable to deſtruction from the periſhable nature of its materials, or the cataſtrophe which awaited it on the night of the 2d of Dec. 1755, when one of the attendants, entering the lantern to ſnuff the candles, found it in flames, and, notwithſtanding every exertion, the fire communicated to the uprights, and burned downwards. The unfortunate men deſcended

ſcended from room to room as the fire increaſed, and were at laſt obliged to take refuge, from the fall of burning timbers, in a cavity of the rock, from which they were relieved by a boat the next morning. The wind, unfortunately, blew from the eaſt, and though it cauſed ſuch a ſwell as to prevent landing, did not break on the houſe ſo as to extinguiſh the fire; and thus, in a few days, the whole was deſtroyed, except the iron cramps in the rock.

It is remarkable, that whilſt one of the light keepers, at the commencement of the fire, was looking up at the fire in the cupola of the lantern, a body of melted lead ſhowered down upon him, and he declared a quantity had paſſed down his throat into his ſtomach. He lived only 12 days after being taken on ſhore; and on opening the body, a maſs of lead was taken from the ſtomach, weighing more than ſeven ounces. The curious fact, of his having 12 days ſurvived ſo alarming an accident, was communicated by his attendant ſurgeon, Dr. Spry, to the Royal Society, but the circumſtance appeared ſo improbable, that it did not, at firſt, meet that credit, which future experiments on animals proved he was entitled to.

On the news of the fire reaching London, the proprietors (for by the ſale of Capt. Lovel's original leaſe, the property of the light-houſe was now in many hands,) immediately took meaſures to reſtore it, and appointed one of their members, Mr. Rob. Weſton, to the ſole management of their affairs, and he being recommended to Mr. John Smeaton, F.R.S., by the preſident of the Royal Society, employed this gentleman to deviſe the means, and ſuperintend the erection, of a new building. Mr. S., whoſe originality of genius, and ſoundneſs of judgment, have ſince been ſo generally known, was at that time juſt entering into his profeſſion as a civil engineer, but immediately devoted himſelf to the conſideration of the light-houſe, and ſoon determined upon erecting a ſtone building; and reaſoned, that by making the building very heavy, and uniting all the ſtones firmly together, he ſhould obtain ſuch a weight and ſtrength, as would firmly reſiſt the united action of the wind and water. He determined upon dovetailing the ſtones together, as being a more ſecure method than cramping with iron, and not liable to interruption from the work getting wetted, as would almoſt unavoidably happen in ſuch an expoſed ſituation. On the whole, the building he erected, and which is now ſtanding, may be conſidered as the moſt perfect light-houſe in exiſtence, and gives examples of the beſt kinds of maſonry. We have therefore given drawings of it in the *Plate* of *Light-houſe*, which are taken from a ſuperb work in folio, publiſhed by Mr. Smeaton in 1791, entitled "Narrative of the Building, and Deſcription of the Conſtruction of the Eddyſtone Light-houſe with Stone." It is from the ſame ſource the whole of this article has been compiled.

Fig. 1. is a ſouth elevation of the whole houſe, and *fig.* 2. a ſection of the ſame. A repreſents the landing place; B a natural cave in the eaſt ſide of the rock; D an iron rod, ſerving as a rail to hold by in paſſing up ſteps cut in the rock, to the foot of the ladder occaſionally put out from the entry door at E. At F is a caſcade of water, pouring over a low part of the rock, but this is only momentary, for the ſwell will in an inſtant cauſe it to ſet the other way. In *fig.* 2. *a* B ſhews the upright face of the rock, and the line *a b* the general direction of its *grain* or ſlope. In this figure it is ſeen that, as high as the firſt 14 courſes of ſtone work, the building is entirely ſolid. Here the entry F commences, but excepting this cavity, and the ſtaircaſe X, the ſolid ſtill continues to the floor of the loweſt chamber G, which is the ſtore room, and H the door at which the ſtores are drawn up and received. I is the upper ſtore room; K the kitchen containing the fire-place L, from which the ſmoke aſcends by a copper funnel *m*, through the bed room M and lantern N, to the ball on the top of the cupola O. The aſcent from room to room is by the perforations through the middle of each floor, a moveable ſtep ladder being uſed for the attendants; but ſtore may be drawn up from the lower room into any other. P is the railing forming the balcony; its floor is covered with very thick ſheet lead, turned down over the cornice Q, which ſurmounts the column of the building. R is the ſtone baſement of the lantern, and N the glazed part: the cupola O is ſupported by eight caſt-iron ſtandards, between which the copper window frames are fixed: the ſtandards have claws at bottom, which are ſcrewed to flat iron bars reſting upon the ſtone work. By this means the whole lantern is framed together; and to ſtrengthen it, the window frames are caſt with diagonal bars, as ſhewn in *fig.* 2. The whole lantern is held down by eight bolts at its angles, paſſing down through the balcony floor; one of theſe is ſeen at *d*: S is the door to the balcony. The lantern is lighted by 24 candles arranged in two iron circles, one ſix feet four inches diameter, containing 16 lights; and the other, three feet four inches diameter, holding eight candles. Theſe circles are ſuſpended by cords going over pullies, ſo that they mutually riſe and fall parallel, and counterbalance each other. By this arrangement either circle can be drawn down to ſnuff the candles, which is done every half hour, without loſing the whole light. Having thus deſcribed the general outline of the building, the minutia of its conſtruction comes next to be deſcribed, and the manner of uniting the ſtones compoſing it. The ſection, *fig.* 2, ſhews the ſeveral ſteps which were cut in the rock to engraft the ſtone work upon. *Figs.* 1, 2, 3, &c. denote the different courſes of ſtone, each of which makes a level ſurface with the ſtep it is fitted into. The ſeventh is the firſt complete courſe. *Fig.* 3. is a plan of the rock, ſhewing the courſes 1, 2, and 3, laid in their places, and exhibiting the dovetails which are cut in each ſtep to hold the ſeveral ſtones in their places; and theſe ſtones are ſo formed as to enlock the others with them in a manner which will prevent any ſtone quitting its poſition. The dark ſhaded ſtones are *moor* ſtones, while the lighter ſorts are Portland ſtone. *Fig.* 4. is a plan of the ſeventh or firſt complete courſe, ſhewing a central ſtone with four dovetails uniting it to four others, and theſe tying in the remainder. All the ſolid courſes are laid in this manner to the fourteenth, which, as before mentioned, completes the entire ſolid. Every courſe is laid in ſuch a manner upon the one beneath it, that all the joints break each other, as maſons term it, that is, immediately above and below the joints of any courſe the middle of a ſolid ſtone is diſpoſed. The ſeveral courſes are retained upon each other, to prevent them ſliding ſideways, by means of *joggles*, which are plugs or cubes of hard black marble, ſhewn by the dark ſquares in *fig.* 2, and in the plan, *fig.* 4, to be received one-half through every two adjacent courſes. All the courſes of the entire ſolids have a central joggle *f*, and eight others, *g*, arranged in a circle round it, as ſhewn in *fig.* 4. Above the entire ſolid, the centre ſtone is omitted to leave the well-hole for the ſtair-caſe, X, or rather, it is compoſed of four ſtones, united by hook or dovetail joints, to form, when put together, one piece, large enough to have the well-hole through its centre, and the exterior ſtones are united to it as a central piece in the ſame manner, as *fig.* 4. In theſe courſes the continuity of the ſtones being ſomewhat broken, double the number of joggles, *h*, and thoſe half the ſize, are introduced between the courſes. It is to be obſerved, that none of the joggles, except the centre ones, come immediately over the others, as the figure would infer, but they break joint with each other to give every part of the ſolid an equal ſtrength. Above the ſolid, a new ſyſtem of building was neceſſarily adopted: the lower courſes were compoſed of Portland ſtones to fill up the centre, and moor ſtones, as being more durable, to make the outſide. The whole of the upper works are of moor ſtone; and dovetailing being no longer practicable, the ſtones are united by iron cramps and joggles, as ſhewn in *fig.* 7, which is a plan of the upper or bed-room M. Each ſtone is here ſeen to have an iron cramp to join it to its neighbour, and has a ſmall marble joggle to unite it with that above it. The vertical joints are rendered impervious to water, by cutting a notch between every two adjacent ſtones, ſo that when they come together it forms a hole of a lozenge ſhape, and a piece of ſtone being put down into this hole with mortar, makes a perfect joint, at the ſame time increaſing the bond of the ſtones. This kind of joint is partly ſeen in *fig.* 8, at *n*, but one-half is hid by the iron cramps *r*, *r*, extending over every joint. In this figure they are ſeen inclined, that they may take firmer hold of the ſtones *s*, *s*, forming the ſides of the apertures T, for the window. The ſtones of the different floors are dovetailed together, as in *figs.* 5 and 7, and are rather arched on the lower ſide, as ſhewn in *fig.* 2. To retain the thruſt of theſe arches, every courſe from which a floor ſprings, is bound by an endleſs chain inlaid in the ſtone work, as in *fig.* 5, and run in ſolid with lead. The chain is ſhewn enlarged in *fig.* 6. *Fig.* 7. is a plan of the bed-room M, ſhewing the diſpoſition of the three cabin beds *k*, *l*, *m*, with a window between each. The dark ſpot *m* is the ſmoke funnel, and *n* is the place for a clock.—The reader is now tolerably well acquainted with the conſtruction of Mr. Smeaton's light-houſe; but in ſuch a peculiarly expoſed ſituation, every trifling operation was attended with difficulty, and demanded thought and ingenuity to deviſe the means of accompliſhing it. On this account we ſhall briefly follow Mr. Smeaton through his narrative, though it relates circumſtances which, if recorded in the account of a common building, would appear impertinently minute. The ſeaſon when Mr. Smeaton firſt took up the buſineſs of the light-houſe not being favourable for a viſit to the rock, he did not attempt it till April 1756, before which time he had deſigned the general principles of the building. He found upon the rock the irons of both the former erections, and ſeveral of the moor ſtones of the late building lying in the gut, which was a narrow channel of twelve feet deep between the houſe rock, and a reef of rocks to the weſtward, in which channel the boats coming to the houſe could lie in fair weather. His firſt viſit was employed in obſervations on the rock, and in experiments of the time requiſite to drill and pick holes of a certain dimenſion, that he might eſtimate the time neceſſary to complete the work on the rock. In ſucceeding voyages he took dimenſions of every part to enable him to make an accurate model, to which he could adapt a model of the intended building. The unfavourable days at ſea were employed on ſhore in examining the ſtone in the country round, a convenient ſituation for a work-yard, &c. The dimenſions of the rock were taken by the following means: He fixed up the circle of a theodolite, with its index, in the centre of the rock, and levelled it with the ſpirit-level; a light rod was fixed to the index, long enough, when turned round, to reach all parts of the rock; it was provided with a ſpirit-level to ſhew when it ſtood horizontal. It is obvious that this rod, when turned round, would deſcribe a horizontal plane, and the depth of any point of the rock beneath this plane was aſcertained by a rod ſet up vertically upon the point in queſtion, and applying the horizontal ruler to it. The diviſions on the vertical rod ſhewed the depth; and the diviſion of the horizontal ruler ſhewed the diſtance from the centre, and the degrees of the theodolite circle pointed out the direction. By theſe means the poſition and altitude of thirty-two principal points were obtained, which were well marked upon the rock, and a line being ſtretched from one of theſe points to another, gave the means of determining the poſition of the iron ſtanchions, or any thing elſe which was remarkable. Having thus, in ten voyages, made all the neceſſary obſervations on the rock, and determined upon regulations for the management of the work, he returned to London, and, in his way, viſited the various ſtone quarries in Devonſhire, and the iſles of Portland and Purbeck. He was employed, till the month of July, in making exact models of the building, when he returned to Plymouth, where he found a veſſel, the Neptune Buſs, which had been fitted up for exhibiting a temporary light during the period of rebuilding the houſe. From ſome miſunderſtanding between the Board of Trinity and the proprietors, this veſſel was not employed in this manner, but was devoted to Mr. Smeaton's uſe, who immediately began the works upon the rock; mooring the Buſs near the rock to ſerve as a retreat for the workmen, who were frequently driven off by the waves. In the month of September the three lower ſteps of the rock were completed, and the upper ones in a ſtate of great forwardneſs; after which time, bad weather prevented much more being done that year, and in November the Buſs left her moorings to return to Plymouth, in which voyage ſhe was driven to ſea, and narrowly eſcaped ſhipwreck. Thus concluded the operations of the year 1756. The winter ſeaſon was paſſed in preparing ſtone work on ſhore, in building boats, and, by Mr. Smeaton, in a long and valuable ſeries of experiments on the different kinds of cements, which could be applied to the building.

In May 1757, the Buſs was carried out and moored, and on the 12th of June the loweſt and firſt ſtone was laid in its place; from the great uncertainty of the weather every ſtone was ſo contrived, that it was of itſelf in a condition to reſiſt the waſh of the ſea, even when it was immediately laid, and before it was hardened. For this purpoſe, each ſtone had one or two holes drilled through it before it left the work-yard, and this hole being continued a few inches into the rock or the ſtone beneath, a ſtrong trenail, or oaken pin, was driven through it, to pin it faſt in its place: as the dovetails did not of courſe fit perfectly cloſe into each other, but left ſpace for the mortar; notches were cut in the edges of each ſtone to receive ſtrong oak wedges, which held them firm until the mortar came to its ſolidity. As a further precaution to defend the mortar, all the outward joints were coated over with plaſter of Paris, as a temporary expedient. The work went on rapidly in this manner, and the ſecond courſe was nearly ſet in a few days; but a gale ſprang up, which obliged them to quit the work, leaving a few ſtones of the ſecond courſe, which could not be ſet, lowered down into their places, and chained ſtrongly to the rock, by lines inſerted into the holes made in each of the ſtones, to lift them by; and one of the moſt expoſed was ſecured, by laying upon it, when in its dove-tail, a weight of lead of five cwt. in form of a hemiſphere. A ſtorm came on, and it was afterwards found, that this weight had been lifted by the waves, ſo that the ſtone beneath it had eſcaped and was loſt, as were four others, from which circumſtance the force of the ſea on the rock may be imagined. New ſtones were immediately prepared, and the work renewed. In the progreſs of the work, it conſtantly happened, after all precautions, that the cement was waſhed away in particular places, and it was always repaired the firſt opportunity with Pozzolana or Dutch terras; which repairs, if they withſtood one rough tide, were never found to fail afterwards; but ſome places were found ſo difficult, that it became neceſſary to mix oakum, chopped very ſmall, with the mortar, and this method always ſucceeded. On the 11th of Auguſt the ſix baſement courſes were completed, and the firſt entire courſe, N° 7, was begun. All the ſtones for this courſe were fitted and put together in the work-yard, as ſhewn in *fig.* 4. They are numbered, ſo that after being taken to pieces, they could be reſtored to the ſame relative poſition on the building; but to do this accurately, while they were in the work-yard, radial lines were drawn from the centre to the circumference, ſo as to interſect each ſtone; and concentric circles were drawn through the middle of each tier of ſtones. Where any of theſe lines croſſed the joints, a nick was ſawn in the edge of the ſtone, that the mark might be felt as well as ſeen; and by the coincidence of theſe lines the ſtones were ſet with the greateſt accuracy. On the ſtones arriving at the work, the central ſtone was firſt ſet; the hole to receive the centre joggle was cut through the centre of courſe ſix, and the joggle ſet up therein, as ſhewn in *fig.* 2, and the centre ſtone of courſe ſeven let down upon it, a mortar bed being made beneath. When the ſtone was thus fixed, the joints round the joggle were filled in by grouting, which is mortar made very thin and poured in from ladles. The four ſtones ſurrounding the centre were now ſet, and the work proceeded thus to the circumference, every ſtone being wedged and trenailed as ſoon as ſet, and the joints grouted. To fix the eight ſmaller joggles, they were ſet, wedged, and grouted into their holes in the lower courſe; but the holes for their reception in the lower ſide of the upper courſe, being only cut half through, did not admit of wedging; they were therefore fixed by the mortar only, as much being put on the top of the joggle as would nearly fill the hole, but not quite, and the remainder was introduced through a hole previouſly drilled through the ſtone, and forced down by a wooden ramrod.

The mortar uſed in the building was compounded of equal portions of lime and pozzolana. The lime was burned from the blue Lyas limeſtone found near Watchet, a ſmall ſeaport in Somerſetſhire. It was carried out in tight caſks, which were opened at the rock, and a ſmall quantity beat up in a ſtrong bucket with a wooden peſtle, and uſed immediately. The work proceeded in the ſame manner without any deviation or accident, except now and then loſing a few ſtones by ſtorms, until the end of September, when the ninth courſe, being completed, the work was given up for the year, and the Buſs left her moorings.

During the winter, the buoy of the moorings for the Buſs was loſt, but was recovered on the 11th of May, 1758. Yet, before any work could be begun, the chains were broken, and the buoy of the anchors having got looſe, the moorings were loſt; much time being conſumed in preparing new ones, it was the 2d of July before the work was renewed; but by the 8th of Auguſt, the 14th courſe, completing the entire ſolid, was laid, and by the 20th the entry door was covered in, and by the 24th of September, the whole of the ſolid, up to the ſtore-room floor, was finiſhed. Above this the method of working was totally altered, but not being now ſo liable to the action of the ſea, it became leſs difficult, and requires leſs deſcription. In addition to what has been ſaid before, the iron cramps were all filled in their places with lead, and a whole courſe was done at once, by putting each cramp into a kettle of red-hot lead, till it was equally hot. A ſmall quantity of oil was poured into the holes in the ſtone, and the hot cramp put in: this oil cauſed the lead, when poured in, to occupy every cavity in the ſtone.

On the 30th of September, the work had arrived at the ſtore-room floor, and here the iron chain, ſhewn in *fig.* 5, was let into the ſtone, and filled in with lead in the following manner:—the chain was oiled before putting it in, and the groove divided into four parts by dams of clay. Two kettles were uſed, which together would hold lead enough to fill the whole groove, which was 11 cwt. In theſe the lead was made red-hot, and two perſons with ladles filled the lead into the ſame quarter of the groove. As ſoon as it was at all ſet, they removed one of the clay dams, and filled the next quarter, pouring the lead on the end of the firſt quarter, till it re-melted and united with the ſecond. The dam at the oppoſite end of the firſt quarter was now removed, and the third filled, and then the 4th. By this means the lead was all round united in one maſs.

The centering for the floor was next ſet up, and the floor partly put together, the outward ſtones being ſet firſt, and then the centre ones. When the firſt room had been thus finiſhed, Mr. Smeaton propoſed exhibiting a temporary light during the winter, and, by fixing three floors in the well for the ſtaircaſe, to form ſtore rooms, and lodging for two men: but this idea was given up, as it did not meet the approbation of the Trinity corporation, and the work was, on the 7th of October, left for the year, the floor being partly finiſhed. The winter was ſpent in preparing the iron, glaſs, and copper work for the lantern; and the ſpring in unſucceſsful endeavours to recover the moorings which were again loſt, and on the 5th of July the work was begun again. They found one of the ſtones for the floor, which was lodged in the ſtore room H the year before, had been waſhed down the well, and thence through the entry into the ſea, though it weighed four or five cwt. The ſtones for the building had hitherto been raiſed out of the boats, by what are termed *ſhears*, formed of two poles, united at top, and their feet pitched on the rock cloſe to the building, at a proper diſtance aſunder. A block of pullies was ſuſpended from the top of the two beams, to take up the ſtone. The ſhears were ſupported by a tackle called a guys, which was attached to the top of the ſhears, and hooked to the far ſide of the building, ſo that the ſtone, being raiſed up from the boat by a windlaſs fixed on the rock at Y, *fig.* 1, the guy was drawn in to ſwing the ſtone over the building. When the work got above the entry E, the ſtones were landed into it, and drawn up the well X by a tackle ſuſpended from a ſmall triangle ſet over the well; but when the floor was covered in, the hole in the centre being too ſmall to let the ſtones come up, a ſmaller pair of ſhears were made to lie upon the building and riſe as it advanced. Theſe were worked by a windlaſs ſet up in the ſtore room H, and as they hung over the ſides of the building, they drew up the ſtones clear of the wall. The work proceeded in this manner till the 17th of Auguſt, when the laſt piece of the cornice Q was fixed, which completed the whole column, and the workmen were enabled to lodge in the building. The balcony rails P, and the ſtone baſement R of the lantern, were ſoon completed; and by the 26th, the ſtairs and all the maſonry were finiſhed. The iron frame of the lantern was next ſcrewed together in its place, all the joints being firſt ſmeared with thick white lead and oil to prevent them from ruſting: it was then raiſed up on wedges a ſmall height, and lead poured in the joint between it and the ſtone to make a ſolid bed for it upon the ſtone. On the 17th of September, the copper cupola O was ſet up, by a particular kind of ſhears made for the purpoſe, the guys, in different directions, being faſtened to booms projected out from the ſeveral windows of the upper room. The next day the ball, which was double gilt, was ſcrewed on; and by October the 16th, an electrical conductor was fixed, which finiſhed the edifice. A light was then exhibited, which has been continued ever ſince without any particular occurrence, or any accident produced by the many violent ſtorms which have happened ſince. Mr. Smeaton has, in the title page of his narrative, given a repreſentation of the houſe in a ſtorm, as ſeen through a teleſcope from Plymouth, when the waves daſh up againſt the building, till they meet the cornice Q, by which the water is thrown off in all directions in a white column, which envelopes the houſe like a ſheet, and riſes to at leaſt double its height, though the top of the ball is 100 feet above low water. See BEACONS.

LIGHT *Infantry.* See INFANTRY. When the light infantry companies are in line with their battalions, they are to form and act in every reſpect as a company of the battalion; but when otherwiſe diſpoſed of they may looſen their files to ſix inches.

The open order of light infantry is uſually two feet between each file.

The files may be extended from right, left, or centre; in executing it, each front rank man muſt carefully take his diſtance from the man next to him on that ſide from which the extenſion is made: the rear rank men conform to the movement of their file leaders.

When light infantry men fire in extended order, it is to be a ſtanding rule, that the two men of the ſame file are never unloaded together; for which purpoſe, as ſoon as the front rank man has fired, he is to ſlip round the left of the rear rank man, who will take a ſhort pace forward, and put himſelf in the other's place, whom he is to protect while loading.

The extended order of light infantry varies according to circumſtances and ſituations. They may ſometimes looſen their files to three times the diſtance of open order. But the general rule is to allow convenient intervals for the rear rank men to ſlip by, and return after they have fired.

All movements of light infantry, except when firing, advancing, or retreating, are to be in quick time.

The officer commanding the company will be on the right, covered by a ſerjeant; the next on the left, alſo covered by a ſerjeant. The youngeſt officer in the rear. In extended order the poſt of the officers and ſerjeants is always in the rear at equal diſtances.

In marching by files the officer commanding leads: by diviſions each officer leads one. The ſupernumerary officer, if there be one, is in both caſes with the officer commanding, ready to obey any directions he may receive from him.

The arms of light infantry in general will be carried ſloped and with the bayonet fixed. Flanking or advanced parties, however, or parties in particular ſituations, may carry them trailed, and without bayonets, for the purpoſe of taking a more cool and deliberate aim.

When the light infantry is ordered to cover the line to the front, the diviſions will move from their inner flanks round the flanks of the battalions, and when at the diſtance of fifty paces, the leading flanks will wheel towards each other, ſo as to meet oppoſite the centre of the battalion, opening their files gradually from the rear, ſo as to cover the whole extent of the battalion.

The files are not to wait for any word of command, but to halt and front themſelves. In this poſition, and in all poſitions of extended order, the poſt of the officer commanding is in the rear of the centre, and the movements are to be regulated by the company belonging to the battalion, which governs thoſe of the line. For a fuller explanation of light company manœuvres, ſee page 273 to page 281 of Infantry Regulations.

Light infantry men, like huſſars, are frequently detached to act as ſcouts on the flanks, in the front, or with the rear guard of the body of troops to which they belong. They then acquire the appellation of ſkirmiſhers, and being previouſly told off for that ſpecific duty, they advance and form in the front in rank entire; which is effected by each man from the rear rank placing himſelf on the left of his file leader. The rank entire may be reſorted to for various purpoſes during the movements of one or more battalions, ſince it may ſerve not only to cover them from the enemy's obſervation, but in ſome caſes, eſpecially in foggy weather, will itſelf appear a larger body than it really is. Too much attention cannot be given to the organization of light troops on foot. They are very properly called the eyes of an army, and ought always to be conſidered as indiſpenſably neceſſary.

LIGHT-*Room,* is a ſmall apartment incloſed with glaſs windows, near the magazine of a ſhip of war. It is uſed to contain the lights by which the gunner and his aſſiſtants are enabled to fill the cartridges with powder, to be ready for action.

LIGHT *Troops,* in *Military Language,* generally denote all horſe and foot which are accoutred for detached ſervice.

LIGHT *Water-line,* in *Naval Architecture,* the line of floatation of the ſhip, before ſhe takes in her cargo.

LIGHTEN, in the *Manege.* To lighten a horſe, or make him light in the fore-hand, is to make him freer and lighter in the fore-hand than behind. If you would have your horſe light, you ought to keep him always diſpoſed to a gallop, when you put him to a trot; and after gallopping ſome time, you ſhould put him back to the trot again.

LIGHTER, a large open veſſel, generally managed with oars, common on the river Thames, and on other rivers and canals; where it is uſed for the carriage of timber, coals, ballaſt, and any goods to or from a ſhip, when ſhe is to be laden or delivered. There are alſo ſome lighters furniſhed with a deck throughout, in order to contain thoſe merchandizes which would be damaged in rainy weather: theſe are uſually called *cloſe-lighters.* See BOAT.

LIGHTER-*Men.* See COMPANY.

LIGHTFOOT, JOHN, in *Biography,* the ſon of a clergyman, was born at Stoke upon Trent, in Staffordſhire, in the year 1602. He received his grammar learning at Moreton-green, near Congleton, Cheſhire, after which he was entered a ſtudent of Chriſt's college, in the univerſity of Cambridge. Here he applied himſelf with much diligence, and made ſo great a proficiency in claſſical literature, and the ſtudies connected with it, that he was reckoned the beſt orator among the under graduates of the univerſity. At the age of nineteen he quitted the univerſity, and engaged himſelf as aſſiſtant to his old ſchool-maſter, who had, at that time, removed from Cheſhire to Repton in Derbyſhire. Having continued in this ſituation about two years, he took orders, and ſettled as curate at Norton-under-Hales, in Shropſhire: about the ſame time he became chaplain to ſir Rowland Cotton, and reſided in his family. This gentleman, being a perfect maſter of the Hebrew tongue, engaged Mr. Lightfoot in the ſtudy of that and the other Oriental languages. He followed his patron to London, and would have proceeded with him to the continent, but the living of Stone, in Staffordſhire, being offered him, he preferred ſettling there, as it like-which gave him an opportunity of entering upon the marriage ſtate, which he immediately embraced. Here he found the means of ſtudy exceedingly ſcanty, and in the courſe of a few months reſigned the living of Stone, and removed to Hornſey, near London, a ſituation which he choſe, on account of its vicinity to the metropolis, where the ſources of learning were very abundant. He was now a frequent attendant at the library of Sion-college, which afforded him the moſt ample means of ſupplying all his literary wants. In 1629, Mr. Lightfoot publiſhed his firſt piece, entitled "Erubhim; or Miſcellanies Chriſtian and Judaical, and others, penned for the recreation of vacant hours." In 1630, he was preſented by ſir Rowland Cotton to the rectory of Aſhly, in Staffordſhire, and immediately removed to his pariſh, in which he lived twelve years, applying himſelf with indefatigable diligence in ſearching the ſcriptures, and in the performance of various duties attached to his office, as a conſcientious clergyman. He was next appointed by the Long Parliament a member of the aſſembly of divines at Weſtminſter; and as he could no longer reſide among his pariſhioners he reſigned the rectory, but obtained the preſentation for a younger brother. He arrived in London in 1642, and was almoſt immediately choſen miniſter of St. Bartholomew's, behind the Royal Exchange. In the aſſembly of divines, which met in June 1643, Mr. Lightfoot became diſtinguiſhed for his eloquence in debate, and activity in buſineſs. He was friendly to the Preſbyterian form of church government, which he declared in a ſermon before the houſe of commons, he verily believed was "according to the pattern in the mount." In 1643 he was appointed maſter of Catherine-hall, in Cambridge, and in the ſame year he was preſented to the living of Much-munden, in Hertfordſhire. In 1644 he publiſhed the firſt part of his "Harmony of the New Teſtament," with a plan of his whole deſign, and continued afterwards to ſend out, at different periods, the other branches of the ſame work. In 1652, Mr. Lightfoot took the degree of doctor of divinity, and went through all the regular exerciſes, on that occaſion, with great applauſe. In 1653 he was choſen vice-chancellor of the univerſity of Cambridge, the duties of which important office he performed with exemplary diligence and fidelity. Upon the reſtoration of king Charles II. Dr. Lightfoot offered to reſign the maſterſhip of Catherine-hall in favour of Dr. Spurſtow, but upon his declining to accept it, our author obtained a confirmation from the crown of that place, and of his living. For theſe marks of royal favour he was chiefly indebted to the kindneſs of archbiſhop Sheldon, who, out of pure reſpect for his learning and talents, undertook to ſerve him. Soon after this he was collated, through the intereſt of lord-keeper Bridgman, to a prebend in the cathedral church of Ely. In 1661 he was appointed one of the aſſiſtants at the conference at the Savoy on the ſubject of the liturgy, but he attended only twice, on account of the violence diſplayed in the debates. He now gladly withdrew as much as poſſible from the world, in order that he might ſpend his time in ſtudies to which he was attached, and which he proſecuted with vigour to the laſt. His publications would have been more numerous, but the expence of them was more than he could bear, and he never was ſufficiently patronized by the public to intereſt the bookſellers in his behalf. A ſhort time before his death he was, however, requeſted by them to collect and methodiſe his works, in order that they might be printed in an uniform manner. He died in December 1675, before he could accompliſh the taſk required of him, in the 74th year of his age. Dr. Lightfoot was indefatigable in his purſuits, and extremely temperate in his mode of living. He lived in the greateſt harmony among his pariſhioners, being eaſy of acceſs, affable, communicative, hoſpitable, and charitable. As a writer he was one of the moſt ingenious, as well as learned, of our Engliſh commentators, and has furniſhed his ſucceſſors with very valuable materials in the ſame line of ſtudies: he had few equals, and no ſuperior in rabbinical literature; and in this branch of learning his celebrity was ſo great, that many foreigners came to him for aſſiſtance in it. His works were collected and publiſhed in 1684, in two volumes folio. A new edition of them was publiſhed in Holland in 1686, containing all his writings that had been originally given to the world, in the Latin language, and a Latin tranſlation of thoſe which he had written in Engliſh: and a third edition was publiſhed at Utrecht in 1699, by John Leuſden: this impreſſion contained ſome poſthumous pieces, which were compriſed in a third volume. Theſe were, in the following year, publiſhed in an 8vo. volume by Mr. Strype, under the title of "Some genuine Remains of the late learned and pious Dr. John Lightfoot." The doctor was not only indefatigable in his own purſuits, but an encourager of other learned men in their's. He gave great aſſiſtance in completing the Engliſh Polyglott bible, by drawing up a chorographical table prefixed to it, and by ſuperintending the ſheets of the Samaritan verſion, as they were printed: he afforded much pecuniary aſſiſtance to Dr. Caſtell in the publiſhing of his Heptaglott Lexicon, which would otherwiſe have occaſioned his entire ruin for want of ſupport from the learned world: and Dr. Lightfoot was the perſon who excited Mr. Pool to undertake his valuable work entitled "Synopſis Criticorum." Biog. Brit. Gen. Biog.

LIGHTFOOT, JOHN, a diſtinguiſhed Britiſh botaniſt, chiefly known as the author of the *Flora Scotica*, was born in 1735. He was educated at Oxford, where he took the degree of Maſter of Arts, and having entered into holy orders, became chaplain to the late ducheſs dowager of Portland, "that great and intelligent admirer and patroneſs of natural hiſtory in general," as he juſtly denominates her in the dedication of his book. He was recommended to this illuſtrious lady, whoſe accompliſhments gave a luſtre to her high rank, by his taſte for botany and conchology, as well as his courtly and aſſiduous manners, which, accompanied by an habitual pleaſantry and cheerfulneſs, rendered his company generally acceptable. By her grace's influence, we believe, he obtained the rectory of Gotham, in Nottinghamſhire, and ſubſequently the living of Cowley, in Middleſex.

In 1772, the late Mr. Pennant, ſo well known as a zoologiſt, invited Mr. Lightfoot to be the companion of his ſecond tour to Scotland and the *Hebrides*, adviſing him to undertake the "compilation," as he himſelf modeſtly calls it, of a *Flora Scotica*, which Mr. Pennant offered to uſher into the world at his own expence. Theſe generous and flattering offers Mr. Lightfoot gladly accepted, and made the moſt of the opportunity afforded him for "gratifying a favourite affection he had long conceived for the ſcience of botany." He enjoyed "the enchanting proſpect," to uſe his own words, "of examining a country whoſe vegetable productions had been attended to by very few." Our author was juſtly aware that a ſingle ſummer could by no means be ſufficient for the full accompliſhment of ſuch an undertaking, nor would he perhaps have ventured upon it, but for the aſſiſtance of "able and ingenious botaniſts, who had reſided in that country their whole lives," who permitted him "to examine their collections, and freely communicated the obſervations of many years." Theſe were the late Dr. Hope, profeſſor of botany at Edinburgh; the Rev. Mr. (now Dr.) John Stuart of Luſs; and the Rev.

Dr. Burgeſs, the venerable paſtor of Kirkmichael in Dumfriesſhire: three men whoſe urbanity conferred upon their beloved ſcience her moſt attractive charm, as the writer of this can well teſtify. Mr. Stuart was the companion of our travellers in their excurſion, and ſupplied each, in his own line, with much learned information, reſpecting the Erſe nomenclature, as well as the real or ſuppoſed uſes and hiſtory of the native animals and plants. Thus Mr. Pennant was enabled to prefix a compendious *Fauna* to the *Flora* of his friend; and thus Mr. Lightfoot found his path made ſtraight and plain before him, and literally ſtrewed with flowers. He profited likewiſe from the communications of Dr. Parſons, at that time profeſſor of anatomy at Oxford, and of Mr. Yalden, an ingenious young man, whoſe premature death happened ſoon after. Theſe gentlemen had cultivated botany in the courſe of their medical ſtudies at Edinburgh, the latter eſpecially, with eminent ſucceſs. When Mr. Lightfoot's materials were got together, the library, herbarium, and perſonal ſuperintendance, of his friend ſir Joſeph Banks, in conjunction with the help of Dr. Solander, were of the moſt eminent and indiſpenſable uſe; and the compariſon of his cryptogamic ſpecimens with thoſe of Dillenius at Oxford, under the eye of the profeſſor, or rather of his ſon Dr. John Sibthorp, gave the finiſhing ſtroke to his labours. Thus the *Flora Scotica* became ready for publication in 1777, when it appeared in two thick volumes 8vo. with 35, rather indifferently engraved plates, five of which are zoological. The work is diſpoſed according to the ſyſtem of Linnæus, with ſhort eſſential generic and ſpecific characters copied from that author, and references to a few of the beſt figures of each ſpecies. Engliſh, Scottiſh, and Erſe names are ſubjoined, with the general or particular places of growth, duration, &c.; and the account of every plant finiſhes with a longer or ſhorter deſcription in Engliſh, various botanical remarks, and compiled notes of its economical or medical uſes.—The plan and the execution of this work appear calculated to render it one of the moſt popular Floras. It has found its way to the continent, where it is generally quoted, eſpecially for the Cryptogamous claſs, which the author ſays "coſt more time and attention than all the other 23 claſſes together." Yet we have heard that this publication did not, for a long time at leaſt, pay its expences. This certainly did not ariſe from any want of merit; for its only great and radical fault was not known, or at leaſt ſcarcely conſidered ſuch, till lately. Of this notice is taken under the botanical article FLORA. The fault we mean is the compiling deſcriptions from foreign authors, without mentioning whence they are taken; ſo that a ſtudent can never be certain of their juſt application, but, on the contrary, often finds them erroneous or unſuitable, without knowing why. Even in the laſt claſs, on which Mr. Lightfoot beſtowed ſo much pains, the ſynonyms of Linnæus and Dillenius often diſagree, though in many caſes ſuch contrarieties are properly indicated, ſo as to throw original light on the ſubject.

Mr. Lightfoot was for ſome years a fellow of the Royal Society, and was one of the original fellows of the Linnæan Society, the formation of which he contemplated with great pleaſure, though his death happened before he could attend any of its public meetings. Having married the daughter of an opulent miller at Uxbridge, he reſided in that town, and died there ſuddenly in the ſpring of 1788, aged 53, leaving a widow and ſeveral daughters. He was buried in Cowley church, where his grave remained, for ſome time at leaſt, without any memorial. He is ſuppoſed never to have recovered from a diſappointment, reſpecting a living, which his patron, the late duke of Portland, ſolicited from lord chancellor Thurlow, but which the latter did not think fit to beſtow.

The ſubject of our memoir had, in the courſe of his botanical ſtudies, collected an excellent Britiſh herbarium, conſiſting of abundant ſpecimens, generally gathered wild, and in many caſes important for the illuſtration of his work. He had alſo amaſſed, from ſir Joſeph Banks and other friends, a number of exotic plants. The whole was bought, after his death, for 100 guineas, by his majeſty, as a preſent to the queen, and depoſited at Frogmore, the price being fixed by an intelligent friend of the family. The ſpecimens having been for ſome time neglected, were, after a while, diſcovered to be much infeſted with inſects; and as their royal poſſeſſor, having a genuine and ardent taſte for the ſtudy of botany, was anxious for their preſervation, the writer of the preſent article was requeſted to give his advice and aſſiſtance on this ſubject. This led to his frequent invitation as a viſitor at Frogmore, and to a regular courſe of converſations, rather than lectures, on botany and zoology, which her majeſty, and the princeſſes Auguſta and Elizabeth honoured with their diligent attention; the queen regularly taking notes of every lecture, which ſhe read over aloud at its concluſion, to prevent miſtake. The plan of this exemplary mother, on which ſhe has often been heard to deſcant, was, in the education of her royal offspring, to open as many reſources to them as poſſible, in a variety of ſtudies and purſuits; out of which they might ſubſequently make their own choice, and thus be independent of circumſtances for occupation and amuſement. Nor has the herbarium of Lightfoot been conſigned to uſeleſs repoſe. It was allowed to be conſulted frequently, on the ſubject of Scottiſh Willows, and other doubtful matters, while the *Flora Britannica* was preparing; and the preſent biſhop of Carliſle was permitted to make all requiſite uſe of it, for the completion of his valuable paper on Britiſh *Carices*, printed in the ſecond volume of the Linnæan Society's Tranſactions. In the knowledge of theſe two genera of plants, Mr. Lightfoot excelled moſt botaniſts of his day; but the ſpecimens of Linnæus, being compared with his, have brought errors to light, which were never ſuſpected before. S.

LIGHTFOOTIA, in *Botany*, ſo named by L'Heritier, in honour of the author of the *Flora Scotica*. (See LIGHTFOOT.) L'Herit. Sert. Angl. 4. Ait. Hort. Kew. v. 1. 217. ed. 2. v. 1. 343. Willd. Sp. Pl. v. 1. 887. Juſſ. 450.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. *Campanulaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of five equal, acute leaves, broad at the baſe, encompaſſing the middle of the germen. *Cor.* of one petal, in five deep, equal, regular, oblong, ſpreading ſegments, rather longer than the calyx; the very ſhort tube cloſed by five valves, bearing the ſtamens. *Stam.* Filaments five, linear, flat, equal, much ſhorter than the corolla; anthers ſmall, roundiſh, incumbent. *Piſt.* Germen half inferior, ovate, ſtyle thread-ſhaped, about the length of the corolla; ſtigma dilated into three or five, ſomewhat ſpreading, ſegments. *Peric.* Capſule ovate, with three or five cells, opening at the top by as many valves. *Seeds* numerous, ſmall, roundiſh.

Eſſ. Ch. Corolla in five deep ſegments, cloſed at the bottom by valves bearing the ſtamens. Calyx of five leaves. Stigma of three or five lobes. Capſule half ſuperior, of three or five cells, and as many valves.

1. L. *oxycoccoides*. Cranberry-leaved Lightfootia. L'Herit. Sert. Angl. 4. t. 4. Sm. Exot. Bot. v. 2. 19. t. 69.—(Lobelia tenella; Linn. Mant. 120. Thunb. Prodr. 40. L.
parviflora;

parviflora; Berg. Cap. 345.)—Leaves plain, ovato-lanceolate, alternate, reflexed. Stigma three-cleft. Corolla widely ſpreading.—Native of the Cape of Good Hope, as are the two following ſpecies alſo. This was ſent to Kew in 1787, by Mr. F. Maſſon. It is kept in the greenhouſe, and flowers from July to September. The *ſtem* is perennial, ſhrubby, of humble growth, buſhy and ſpreading, not proſtrate, very much branched, often finely downy. *Leaves* numerous, ſmall, alternate, ſeſſile, reflexed, ovate or ſomewhat lanceolate, acute, ſmooth, thick-edged, entire, except a ſmall glandular tooth or two at each ſide. *Flowers* ſmall, on little, terminal, naked, ſimple ſtalks. *Corolla* white, with a tinge of purple along the middle of each ſegment. *Stigma* purple. *Capſule* of three pointed valves forming a cone.

2. L. *tenella.* Curve-leaved Lightfootia. (Campanula tenella; Linn. Suppl. 141.)—Leaves ovato-lanceolate, channelled, cluſtered, recurved. Stigma three-cleft. Corolla widely ſpreading, with narrow linear ſegments. Stigma three-cleft. Gathered by Thunberg at the Cape. It ſeems a ſtranger to our gardens. L'Heritier confounded it with the preceding, from which it differs in its very numerous, cluſtered, recurved, and deeply channelled *leaves*, and the longer and narrower ſegments of the *corolla*. We cannot but think it more than a variety, though there is ſcarcely any difference beſides what we have mentioned.

3. L. *ſubulata.* Awl-leaved Lightfootia. L'Herit. Sert. Angl. 4. t. 5.—Leaves awl-ſhaped. Calyx almoſt altogether inferior. Corolla moderately ſpreading, with linear ſegments. Stigma five-cleft.—Sent to Kew by Mr. Maſſon in 1787, from the Cape.—This is diſtinguiſhed by its copious, awl-ſhaped, very narrow *leaves*, ſometimes near an inch long. The ſhrubby *ſtem*, with downy *branches*, accords nearly with the two former. The *flowers* ſtand on ſhorter ſtalks, and have longer ſharper calyx leaves, tumid at the baſe, and almoſt perfectly inferior. Segments of the *corolla* moderately ſpreading, recurved, narrow, white or blueiſh. *Stigma* five-cleft. *Capſule* we preſume of five valves.

Nothing can agree more exactly with this as to habit than *Campanula paniculata*, Linn. Suppl. 139, and *Trachelium diffuſum*, 143; but their corolla has a long tube. The capſule of this ſuppoſed *Campanula* has five valves opening at the top, exactly as in *Lightfootia*, not by pores laterally, and the calyx is half ſuperior, ſo that it certainly belongs to the ſame genus, the length of the tube of the corolla being of much leſs importance.

Lightfootia is alſo the name of an arboreſcent genus of the *Polyandria Monogynia*, in Swartz's Fl. Ind. Occ. v. 2. 947, referred to *Prockia* in Willd. Sp. Pl. v. 1. 1214. This is *Lightfootia* of Mart. Mill. Dict. v. 3.

LIGHTNESS. See Levity.

LIGHTNING, in *Phyſiology*, is a large bright flame, darting ſwiftly through the air, and extending every way to a conſiderable diſtance, of momentary duration, and commonly attended with thunder. Some have accounted for this phenomenon by ſuppoſing, that, from the particles of ſulphur, nitre, and other combuſtible matter, which are exhaled from the earth, and carried into the higher regions of the atmoſphere, is formed an inflammable ſubſtance, which, when a ſufficient quantity of fiery particles is ſeparated from the vapour buoyed up into the air, with theſe particles adhering to them by the colliſion of two clouds or otherwiſe, takes fire, and ſhoots out into a train of light, larger or leſs, according to the ſtrength and quantity of the materials. Others have explained lightning by the fermentation of ſulphureous ſubſtances with nitrous acids: ſee Thunder. But in the preſent advanced ſtate of the ſcience of electricity, this is univerſally allowed to be an electrical phenomenon. Philoſophers had not proceeded far in their experiments and inquiries on this ſubject, before they were ſtruck with the obvious analogy between lightning and electricity, and they produced many arguments, *à priori*, to aſcertain their ſimilarity. But the method of verifying this hypotheſis was firſt propoſed by Dr. Franklin, who, towards the cloſe of the year 1749, conceived the practicability of drawing lightning from the clouds: having found, by previous experiments, that the electric fluid is attracted by points, he apprehended, that lightning might likewiſe poſſeſs the ſame property; though the effects of the latter muſt, in an aſtoniſhing degree, ſurpaſs thoſe of the former. The other circumſtances of reſemblance between lightning and electricity remarked by this ingenious philoſopher, and abundantly confirmed by later diſcoveries, are the following: flaſhes of lightning, he obſerved, are generally ſeen crooked and waving in the air; and the electric ſpark drawn from an irregular body at ſome diſtance, and when it is drawn by an irregular body, or through a ſpace in which the beſt conductors are diſpoſed in an irregular manner, always exhibits the ſame appearance.

Lightning ſtrikes the higheſt and moſt pointed objects in its way, preferable to others, as high hills, trees, ſpires, maſts of ſhips, &c. and all pointed conductors receive and throw off the electric fluid more readily than thoſe which are terminated by flat ſurfaces. Lightning is obſerved to take the readieſt and beſt conductor; and this is the caſe with electricity in the diſcharge of the Leyden phial; whence the doctor infers, that in a thunder ſtorm, it would be ſafer to have one's clothes wet than dry. Lightning burns, diſſolves metals, (ſee Fusion,) rends ſome bodies, has been often known to ſtrike people blind, deſtroys animal life, deprives magnets of their virtue, and reverſes their poles; and theſe are well-known properties of electricity.

Lightning not only gives polarity to the magnetic needle, but to all bodies that have any thing of iron in them, as brick, &c.; and by obſerving which way the poles of theſe bodies lie, it may be known, with the utmoſt certainty, in what direction the ſtroke paſſed. Signior Beccaria ſuppoſes, that perſons are ſometimes killed by lightning, without being really touched by it; a vacuum of air only being ſuddenly made near them, and the air ruſhing out of their lungs to ſupply it; and with ſo much violence that they could never recover their breath. In proof of this opinion he alleges, that the lungs of ſuch perſons are found flaccid; whereas, when they are properly killed by the electrical ſhock, the lungs are found inflated: but this hypotheſis is controverted by Dr. Prieſtley. In order to demonſtrate the identity of the electric fluid with the matter of lightning, by actual experiment, Dr. Franklin contrived to bring lightning from the heavens, by means of an electric kite, which he raiſed, when a ſtorm of thunder was perceived to be coming on; and with the electricity thus obtained, he charged phials, kindled ſpirits, and performed all other electrical experiments, which are uſually exhibited by an excited globe or tube. This happened in June, 1752, a month after the electricians in France, of whom the moſt active were Meſſrs. Dalibard and Delor, followed by Mr. Mazeas and M. Monnier, purſuing the method which he had propoſed, had verified the ſame theory; but without any knowledge of what they had done. In April and June, 1753, he diſcovered that the air was ſometimes electrified poſitively, and ſometimes negatively; and found that the clouds would change from poſitive to negative electricity ſeveral times in the courſe of one thunder-guſt. He ſoon perceived that this important diſcovery was capable of being applied to practical uſe, and propoſed a method, which he ſoon accompliſhed, of ſecuring buildings from being damaged by lightning, by means of conductors. The Engliſh philoſophers had not been leſs attentive to this ſubject than their neighbours on the continent; but for want of proper opportunities for trying the neceſſary experiments, and from ſome incidental circumſtances that were unfavourable, they had failed of ſucceſs. However, in July, 1752, Mr. Canton ſucceeded; and in the following month, Mr. Wilſon and Dr. Bevis obſerved nearly the ſame appearances which Mr. Canton had obſerved before. Mr. Canton alſo ſoon after obſerved, in a number of experiments, that ſome clouds were in a poſitive and ſome in a negative ſtate of electricity; and that the electricity of his conductor would ſometimes change from one ſtate to the other, five or ſix times in leſs than half an hour. This variable ſtate of thunder clouds was diſcovered by S. Beccaria, before he heard of its having been obſerved by Dr. Franklin, or any other perſon: and he has given a very exact and circumſtantial account of the external appearances of theſe clouds. From his obſervations of the lightning abroad, and of his apparatus within doors, he inferred, that the quantity of electric matter, in an uſual ſtorm of thunder, is almoſt inconceivably great, conſidering how many pointed bodies, as trees, ſpires, &c. are perpetually drawing it off, and what a prodigious quantity is repeatedly diſcharged to or from the earth. This quantity is ſo great, that he thinks it impoſſible for any cloud or number of clouds to contain it all, ſo as either to diſcharge or receive it. Beſides, he obſerves, that, during the progreſs and increaſe of the ſtorm, though the lightning frequently ſtruck to the earth, the ſame clouds were the next moment ready to make a ſtill greater diſcharge, and his apparatus continued to be as much affected as ever; and, therefore, the clouds muſt have received at one place, in the ſame moment when a diſcharge was made from them in another: and, upon the whole, he infers, that the clouds ſerve as conductors to convey the electric fluid from thoſe places of the earth that are overloaded with it, to thoſe which are exhauſted of it. This electric matter, the riſe of which, from the earth into the higher regions of the atmoſphere, is aſcertained by the great quantities of ſand, aſhes, and other light ſubſtances, carried up with it, and ſcattered uniformly over a large tract of country, wherever it iſſues, attracts to it, and bears up with it the watery particles that are diſperſed in the atmoſphere. It aſcends into the higher regions of the atmoſphere, being ſolicited by the leſs reſiſtance it finds there than in the common maſs of the earth, which, at theſe times, is generally very dry, and conſequently highly electric. The ſame cauſe which firſt raiſed a cloud, from vapours diſperſed in the atmoſphere, draws to it thoſe that are already formed, and continues to form new ones till the whole collected maſs extends ſo far as to reach a part of the earth where there is a deficiency of the electric fluid. Thither, too, will thoſe clouds, replete with electricity, be ſtrongly attracted, and there will the electric matter diſcharge itſelf upon the earth: a channel of communication being in this manner formed, a freſh ſupply of electric matter will be raiſed from the overloaded part, and will continue to be conveyed by the medium of the clouds, till the equilibrium of the fluid between the two places of the earth be reſtored. When the clouds are attracted in their paſſage by thoſe parts of the earth, where there is a deficiency of the fluid, thoſe detached fragments are formed, and alſo thoſe uniform deſcending protuberances, which are, in ſome caſes, the cauſe of *Water-ſpouts* and *Hurricanes;* which ſee.

That the electric matter, which forms and animates the thunder-clouds, iſſues from places far below the ſurface of the earth, and that it buries itſelf there, is probable from the deep holes that have, in many places, been made by lightning; and from the flaſhes that have been ſeen to ariſe from ſubterraneous cavities and from wells; as well as from the inundations accompanying thunder-ſtorms, and occaſioned by water burſting out of the bowels of the earth. The greateſt difficulty attending this theory of the origin of thunder-ſtorms relates to the collection and inſulation of electric matter within the body of the earth. With reſpect to the former, this ingenious philoſopher has nothing to ſay: ſome operations in nature are certainly attended with a loſs of the equilibrium in the electric fluid, but no perſon has yet aſſigned a more probable cauſe of the redundancy of the electric matter, which, in fact, often abounds in the clouds, than what we may ſuppoſe poſſible to take place in the bowels of the earth: and ſuppoſing the loſs of the equilibrium poſſible, the ſame cauſe that produced the effect would prevent the reſtoring of it; ſo that not being able to force a way, at leaſt one ſufficiently ready, through the body of the earth, it would iſſue at the ſame convenient vent into the higher regions of the air, as the better paſſage. S. Beccaria obſerves, that a wind always blows from the place from which the thunder-cloud proceeds; and it is certain, that the ſudden congregation of ſuch a prodigious quantity of vapours muſt diſplace the air, and repel it on all ſides. A great number of obſervations relating to the deſcent of lightning, confirm his theory of the manner of its aſcent: for, in many caſes, it throws before it the parts of conducting bodies, and diſtributes them along the reſiſting medium, through which it muſt force its paſſage. Upon this principle, the longeſt flaſhes of lightning ſeem to be made, by its forcing into its way part of the vapours in the air. One of the principal reaſons why thoſe flaſhes make ſo long a rumbling, is their being occaſioned by the vaſt length of a vacuum, made by the paſſage of the electric matter. For although the air collapſes the moment after it has paſſed, and the vibration, on which the ſound depends, commences at the ſame moment; yet, if the flaſh was directed towards the perſon who hears the report, the vibrations excited at the nearer end of the track will reach his ear much ſooner than thoſe excited at the more remote end; and the ſound will, without any repercuſſion or echo, continue till all the vibrations have ſucceſſively reached him. Mr. Lullin, in order to account for the production of electricity in the clouds, made a long inſulated pole to project from one ſide of the Alps, and obſerved, that when ſmall clouds of vapour, raiſed by the heat of the ſun, roſe near the foot of the mountain, and aſcended along the ſide of it: if they touched the extremity of the pole only, it was electrified; but if the whole pole, and conſequently part of the hill on which it ſtood, was likewiſe involved, it was not electrified. Whence he concludes, that the electricity of the clouds is produced by their paſſing through the air while the ſun ſhines upon them. But to which of theſe two circumſtances, namely, the motion through the air or the action of the ſun's rays, this was owing, he could not determine, though he made ſeveral experiments for this purpoſe.

Upon the whole, it is eaſy to conceive, that when particular clouds or different parts of the earth poſſeſs oppoſite electricities, ſome being electrified poſitively, and others negatively, a diſcharge will take place within a certain diſtance; or the one will ſtrike into the other, and in the diſcharge a flaſh of lightning will be obſerved. But how the clouds or earth acquire this ſtate, is ſtill a queſtion not abſolutely determined. Mr. Canton queries, whether the clouds become poſſeſſed of electricity by the gradual heating and cooling of the air; and whether air ſuddenly rarefied, may not give electric fire to, and air ſuddenly condenſed receive electric fire from, clouds and vapours paſſing through it. Mr. Wilcke ſuppoſes the air to contract its electricity, in the ſame manner as ſulphur and other ſubſtances do, when they are heated and cooled in contact with various bodies. Thus the air, being heated or cooled in the neighbourhood of the earth, gives electricity to the earth, or takes it from it; and the electrified air, being conveyed upwards by various means, communicates its electricity to the clouds. Others have queried, whether, ſince thunder generally happens in a ſultry ſtate of the air, when it ſeems repleniſhed with ſome ſulphureous vapours, the electric matter then in the clouds may not be generated by the fermentation of ſulphureous vapours with mineral or acid vapours in the air.

Dr. Franklin adviſes perſons who are apprehenſive of danger from lightning, to ſit in the middle of a room, provided it be not under a metal luſtre ſuſpended by a chain, ſitting on one chair, and laying their feet on another. It is ſtill ſafer, he ſays, to bring two or three mattraſſes, or beds, into the middle of the room, and folding them double, to place the chairs upon them, for as they are not ſo good conductors as the wall, the lightning will not chooſe to paſs through them: but the ſafeſt place of all is in a hammock hung with ſilken cords, at an equal diſtance from all the ſides of a room. Dr. Prieſtley obſerves, that the place of moſt abſolute ſafety muſt be the cellar, and eſpecially the middle of it; for when a perſon is lower than the ſurface of the earth, the lightning muſt ſtrike it before it can poſſibly reach him. In the fields, the place of ſafety is within a few yards of a tree, but not quite near it. Nevertheleſs, S. Beccaria cautions perſons not to depend upon the neighbourhood of a higher, or, in all caſes, a better conductor than their own body; ſince, according to his repeated obſervations, the lightning by no means deſcends in one undivided track; but bodies of various kinds conduct their ſhare of it at the ſame time, in proportion to their quantity and conducting power. See on the ſubject of this article Franklin's Letters; Beccaria's Lettre dell' Elettriciſmo; Prieſtley's Hiſtory, &c. of Electricity, paſſim. Lord Mahon (now earl Stanhope) obſerves, that damage may be done by lightning, not only by the main ſtroke and lateral exploſion, but likewiſe by that which he calls the returning ſtroke, that is, by the ſudden violent return of that part of the natural ſhare of electricity (of any conducting body, or of any combination of conducting bodies) which had been gradually expelled from ſuch body or bodies reſpectively, by the ſuperinduced elaſtic electrical preſſure of a thunder cloud's electrical atmoſphere. See an account of his theory and experiments, relating to this ſubject, in his Principles of Electricity, &c. quarto, 1779.

The author of the Philoſophy of Agriculture remarks, that the blaſts occaſioned by lightning are more frequent, he believes, than is uſually ſuppoſed; as he is informed by thoſe who purchaſe extenſive woods, that very many trees, on being ſawed through, are found cracked and much injured by lightning. He had laſt year (1799) a ſtandard apple-tree and a tall apricot tree in full leaf, blaſted at the ſame time by lightning, as was believed. They both loſt all their leaves; the apple-tree, nevertheleſs, put out a new foliage and recovered, and bore fruit this year; but the apricot, which was nailed to a high wall, never ſhewed any returning life. Mr. Tull, he remarks, aſcribes one injury to the health of wheat plants, and frequently their death, to lightning, the effects whereof may be obſerved by the blackiſh parts or patches viſible in a field of wheat, eſpecially in thoſe years which have more thunder ſtorms than uſual, and adds, that againſt this there is no remedy. The erection of frequent metallic points could, as the doctor thinks, alone ſecure a garden or field from this misfortune; which probably occurs more frequently on damp ſituations than on dry ones.

He conceives, that the manner in which lightning deſtroys the life of vegetables may be ſimilar to that in which it deſtroys animal life; which is, he ſuppoſes, by its great ſtimulus, exhauſting the ſenſorial power in the violent action it occaſions, and thus producing total inirritability to the common ſtimuli, which ought to excite the vital actions of the ſyſtem. It may alſo affect vegetables in another way ſimilar to that, which probably alſo happens when their young ſucculent roots are frozen; that is, by burſting their veſſels, as it paſſes through them by its expanſive power; as happens to the large branches of ſome trees, and to ſtone buildings, and other bad conductors of electricity, when they are ſtruck with lightning. The expanſive power of electricity is not only ſhewn by trees and towers being rent by lightning, but by the ſound which ſucceeds the paſſage of it through air; ſince a vacuum, or nearly a vacuum, in reſpect to air, muſt previouſly be made by the preſence of the electric fluid: and the ſides of this vacuum ruſhing together, when the ſtream has paſſed, occaſions the conſequent vibrations of the air, which conſtitute ſound, whether in the audible ſpark of electricity, or the tremendous craſh of thunder. Some other effects on vegetables have been aſcribed by writers to lightning, but they have not yet been ſatisfactorily proved. See ELECTRICITY.

LIGHTNING, *Artificial.* The phoſphorus, when newly made, gives a ſort of artificial lightning viſible in the dark, which would ſurpriſe thoſe who are not uſed to ſuch a phenomenon: the uſual method of keeping this preparation is under water, and if the corruſcations are deſired to be ſeen to the greateſt advantage, the glaſs in which it is kept ſhould be deep and cylindric, and not more than three-fourths filled with water. The phoſphorus put into this water will ſend up corruſcations at times, which will pierce through the incumbent water, and expand themſelves with great brightneſs in the empty upper part of the bottle.

If we compare this artificial corruſcation to the real lightning, we ſhall find, that as in this the fire paſſes unaltered through the water, ſo in that the flaſhes of lightning, which come at intervals, paſs uninterrupted through the moſt denſe clouds, and are not obſtructed by the heavieſt ſtorms of rain, but like the beams of the ſun, or any other fire, paſs uninterrupted through glaſs and water. The ſeaſon of the weather, as well as the newneſs of the phoſphorus, muſt concur to produce theſe flaſhes; for they are as uncommon in winter as lightning is, but in warm weather both are very frequent.

The flame of lightning is generally inoffenſive, and does not, except upon particular circumſtances, ſet fire to any thing that it falls upon; and, in like manner, the flaſhings of the phoſphorus through the water will not burn the fleſh, nor even fire the moſt combuſtible things; though the phoſphorus itſelf, like the lightning, under proper circumſtances, may be a very conſuming and terrible fire. The warmth of the air, or the immediate beams of the ſun, will ſet fire to the condenſed body of the phoſphorus, and it then becomes this terrible fire; and in the ſame manner lightning, when condenſed and contracted, and wrapped up in a vehicle of air, ſo that it does not ſo eaſily diffuſe itſelf through the yielding ether, ſets fire to trees, houſes, or whatever it comes near.

The phoſphorus, while burning, acts the part of a coroſive, and when it goes out reſolves into a menſtruum, which diſſolves gold, iron, and other metals; and lightning, in the ſame manner, melts the ſame ſubſtances. From the whole, it appears that there is much more reſemblance between this phoſphorus and lightning than between gunpowder, or aurum fulminans, and that fire; though theſe have often been ſuppoſed to be nearly allied to its nature. See PHOSPHORUS.

LIGNAC, JOSEPH ADRIAN LE LARGE DE, in *Biography*, a learned French abbè, deſcended from a noble family, and born at Poictiers about the commencement of the laſt century. He was brought up among the Jeſuits, and in the courſe of time was choſen to fill different confidential poſts in that order, and in the Congregation of the Oratory. During a viſit which he had occaſion to pay to Rome, he was introduced to the pope Benedict XIV. and cardinal Paſſionei, who honoured him with attention and friendſhip. He died at Paris in 1762, leaving behind him a conſiderable reputation as a philoſopher, a naturaliſt, and theologian. He was author of "Elements of Metaphyſics deduced from Experience:" "The Poſſibility of Man's Corporeal Preſence in different Places at the ſame Time," in which he attempts to prove that the doctrine of tranſubſtantiation contains nothing in it incongruous with the principles of ſound philoſophy. "An Examination of the Treatiſe de l'Eſprit of Helvetius." As a naturaliſt, we have "Memoirs illuſtrative of Aquatic Spiders:" "A Letter to an American concerning the Natural Hiſtory of M. de Buffon:" and as a divine he publiſhed "The Teſtimony of internal Senſe and Experience, oppoſed to the profane and ridiculous Creed of modern Fataliſts," in three vols. At the time of his death he was employed in compoſing a treatiſe "On the Evidences of Religion."

LIGNE', in *Geography*, a town of France, in the department of the Lower Loire, and chief place of a canton, in the diſtrict of Ancenis; 9 miles N.W. of Ancenis. The place contains 1642, and the canton 5770 inhabitants, on a territory of 137½ kilometres, in 4 communes.

LIGNEA CASSIA. See CASSIA.

LIGNEVILLE, the MARCHESE DI, in *Biography*, an ingenious and learned dilettante at Florence in 1770, who had ſtudied counterpoint ſo ſeriouſly as to be able to ſet the hymn "Salve Regina" in canon for three voices. The compoſition is correct, and neatly engraved, copies of which were given to his friends. In the title of this production, dated 1770, the marquis de Ligneville is ſtyled prince of Conca, chamberlain to their Imperial majeſties, director of the muſic of the court in Tuſcany, and member of the Philharmonic ſociety of Bologna. He was ſon of the famous marſhal Ligneville, who was killed in the gardens of Colorno, a villa belonging to the duke of Parma, during the war of 1733, and was prince of Conca, in the kingdom of Naples, by right of his mother.

LIGNICENSIS TERRA, in the *Materia Medica*, the name of a fine yellow bole dug in many parts of Germany, particularly about Emeric, in the circle of Weſtphalia, and uſed in cordial and aſtringent compoſitions. It is a common ſuccedaneum for the yellow Sileſian bole, where that is not to be had, and is generally eſteemed very nearly, if not abſolutely, equal to it in its virtues.

It is moderately heavy, naturally of a ſmooth ſurface, and of a beautiful gold colour. It eaſily breaks between the fingers, and does not ſtain the ſkin in handling, melts freely in the mouth, and leaves no grittineſs between the teeth, and is immediately diffuſible in water. It makes no effervеſcence with acids; and burns to a fine red colour, and almoſt to a ſtony hardneſs.

Charlton (Foſſ. p. 5.) ſays it is more frequently known by the name of *terra ſigillata Goltbergenſis*.

There is another white bole known by this name. See GOLTBERGENSIS *terra*.

LIGNIE'RES, in *Geography*, a town of France, in the department of the Cher, and chief place of a canton, in the diſtrict of St. Amand; 24 miles S. of Bourges. N. lat. 46° 45'. E. long. 2° 15'. The place contains 1205, and the canton 6955 inhabitants, on a territory of 265 kilometres, in 11 communes.

LIGNITE. This name is given, by Brongniart, to the ſpecies of inflammable foſſils, called *braun kohle* (brown coal) by Werner. The following account, from Brongniart's Traité de Minéralogie, will ſupply the omiſſion of the article *Brown coal* in our work.

The combuſtible minerals belonging to this ſpecies are characteriſed by their ſmell and the products of their combuſtion. The odour which they emit in burning is pungent, often fetid, and has no analogy with that of coal or bitumens. They burn with a pretty clear flame, without bubbling and caking, like coal, and becoming fluid in the manner of the ſolid bitumens; they leave powdery aſhes ſimilar to thoſe of wood, but often more abundant, more ferruginous, and more earthy. The aſhes contain a ſmall portion of potaſh; at leaſt Mr. Majon has found about 3 in 100 in thoſe of the bituminous wood of Caſtelnuovo. Theſe combuſtibles yield an acid by diſtillation, which coal does not.

Lignites vary in colour from deep and ſhining black to a dull earthy-brown: the texture of moſt of the varieties indicates their origin and explains their name. The ligneous texture is often obſervable, though ſometimes it has wholly diſappeared. Its fracture is compact, often reſinous and conchoidal, or ſhining and even.

The external characters of the varieties of this ſpecies vary too much to allow them to be farther generaliſed.

1. *Jet Lignite; Jayet. Pech kohle*, Wern.

This ſubſtance is hard, ſolid, compact, and ſuſceptible of a bright poliſh; it is opaque and of a pure black colour; its fracture is undulated, and ſometimes ſhining like that of pitch. Specific gravity 1.259. It is ſaid to be ſometimes lighter than water; but Brongniart thinks this property rather belongs to the following variety.

Is found in ſtrata of little thickneſs, in marly, ſlaty, calcareous or gritty beds. It ſometimes exhibits the organical texture of wood.

It is found in France; in Provence, at Beleſtat in the Pyrenees; in the department of the Aude, near the village des Bains, ſix leagues to the ſouth of Carcaſſone (this ſometimes contains amber), and near Quilian, in the ſame department, in the communes of Sainte Colombe, Peyrat, and Baſtide; it is ſituated at the depth of ten or twelve yards, in oblique ſtrata between ſtrata of ſand-ſtone; but theſe ſtrata are neither pure nor continuous Jet proper to be worked is found in maſſes, the weight of which is ſeldom 55 pounds. Theſe mines have been wrought for a long time, and have produced a conſiderable quantity of jet, which was cut and poliſhed in the ſame country. It alſo occurs in Germany, near Wittemberg in Saxony, where it is alſo cut and poliſhed. Very fine jet has alſo been found in Spain, in Galicia, and the Aſturias. Is likewiſe ſaid to occur in Iceland, in the weſtern part of the iſland.

Beſides theſe, profeſſor Jameſon has quoted the following localities of pitch-coal or jet lignite; the coal diſtricts of the

Lothians, Fifeſhire, Linlithgowſhire, iſland of Skye, and Cannoby and Sanquhar, in Dumfriesſhire, in Scotland; Newcaſtle, Tindel fells, Bolton and Whitehaven, in England; Auſtria; Hungary, Bannat, Tranſylvania; Upper Luſatia; Sileſia; mount Meiſſner in Heſſia; Würtenberg; Franconia; Bavaria; Salzburg; Italy; Pruſſia.

Of this combuſtible ornaments are made, particularly mourning trinkets; it is poliſhed with water on a horizontal wheel of ſand-ſtone. Jet mixed with pyrites is generally rejected.

2. *Friable Lignite; Moor coal; Moor kohle,* Wern.

This variety occurs in thick and extenſive beds. It is of a lively black, but leſs ſhining than that of the preceding variety. Its great friability is particularly characteriſtic of it. Its ſurface is always cracked, and its maſſes divide with the greateſt facility into a number of cubic fragments; a character which is not found in jet.

Friable lignite is more abundant and conſequently more uſeful than the two firſt varieties. It is found in horizontal banks often thick and extenſive, but is never ſeen in ſuch large maſſes as coal, with which it has been confounded by ſome; it differs not only by its properties but alſo by its geognoſtic ſituation. It occurs in thoſe maſſes of ſand which often fill up vallies in calcareous mountains, or cover the ſides of the hills that ſkirt them. Is alſo found, though more rarely, in clayey marle.

Friable lignite is pretty common in the ſouth of France, ſuch as in the department of Vaucluſe. Alſo as conſiderable maſs at Luette, department des Forêts.

Other localities cited by authors are Leitmeritz, Saatz, and Ellenbogen in Bohemia: Thalern near Krems in Auſtria; Tranſylvania; Moravia; the iſland of Bornholm in the Baltic, and the Faroe iſlands. It occurs more frequently in Bohemia than in any other country. Jam.

It burns without difficulty, but ſpreads a very diſagreeable odour. It can be made uſe of only in manufactures, or to burn lime. Smiths cannot uſe it in their forges.

3. *Fibrous Lignite; Bituminous wood; Bituminöſes holtz,* Wern.

Its colour varies from a clear blackiſh-brown to clove brown; it has a perfectly woody form and texture; conſequently, its longitudinal fracture is fibrous, and its tranſverſal fracture ſhews the yearly layers of the wood. It is more eaſily frangible than wood, and takes a degree of poliſh when cut with a knife.

This lignite often occurs in large maſſes.

It is found in France; in the vicinity of Paris, near St. Germain, in the iſle of Chatou, which appears to be entirely formed of it; and near Vitry on the banks of the Seine, where is a thick bed of trunks of trees well preſerved. In the department of Arriège, the clefts of this lignite are filled with calcareous ſpar. In Liguria, near Caſtelnuovo, at the mouth of the Magra, it is found in thick and extenſive beds. In Heſſia, in the mountains of Ahlberg, the ſtratum is above two yards thick. At Steinberg, near Münden in Hanover, it forms two ſtrata, one of about ten yards, the other of ſix, ſeparated by a bed of rock from twelve to fourteen inches thick. In England, at Bovey near Exeter, there are ſeventeen pretty thick ſtrata, ſituated at a depth of about twenty-two yards under ſand and in potters' clay. In Iceland, where it is very abundant, it is called *Surturbrand;* the trunks which form theſe beds are very diſtinct, and appear merely to have been compreſſed.

To theſe localities we add the following from Jameſon: Scotland, in the fletz-trap formation, accompanied with pitch-coal, in the iſland of Skye; in ſeparate pieces in trapp-breccia in the iſland of Cannay; in fletz lime-ſtone, in the iſland of Skye, and in the independent coal formation in the county of Mid Lothian; Bohemia, in the Saatz and Leitmeritz circles; Auſtria; Tranſylvania; Moravia; Leoban in Stiria; Irſenberg in Bavaria; Upper Palatinate; Landeck in Sileſia; Halle; Merſeburg; Artern and Eiſleben in Thuringia; Kalten-Nordheim near Eiſenach; Wehrau, Upper Luſatia; Würtenberg; Freeienwalde and Königſwalde in Brandenburg; Welterwald; Salzburg; Ruſſia.

But this lignite is ſtill more common in ſmall detached maſſes; it ſometimes accompanies the preceding varieties; ſometimes it is found alone in ſmall layers, in the midſt of banks of clay or ſand. It is met with almoſt every where, and is uſed as fuel in thoſe places where it is abundant.

This combuſtible being ſcarcely decompoſed, and hence rather vegetable than mineral, would not deſerve to conſtitute a variety in a ſyſtem of mineralogy, if it did not paſs by imperceptible degrees into the preceding varieties, and into that which follows.

4. *Earthy Lignite; Earth coal; Erd kohle,* Wern.

Commonly called earth of Cologne, and ſometimes, though improperly, *umber;* but the true umber, which comes from Italy or the eaſt, contains nothing that is combuſtible, whence it cannot belong to this ſpecies.

This ſubſtance is black, or blackiſh-brown mixed with reddiſh. Its fracture and aſpect are earthy; it is fine-grained, eaſily frangible and even friable; it is rather ſoft to the feel. Its ſpecific gravity is nearly that of water. It burns, emitting a diſagreeable ſmell.

It not only often contains vegetable remains, but ſometimes itſelf preſents the texture of wood, without ever poſſeſſing either the colour and luſtre, or the hardneſs of the preceding varieties. It burns ſufficiently well to be uſed as fuel. It gives a gentle and equal heat.

It is found in ſecondary formation in the neighbourhood of coal mines, and more frequently in alluvial land.

As an authentic example of this variety may be mentioned the earthy lignite from the vicinity of Cologne, known in trade by the name of earth of Cologne. It is dug up at a little diſtance from that city, near the villages Brühl and Liblar, where it forms very extenſive beds of eight or ten yards in thickneſs, which are ſituated under elevated ground. It is immediately covered with a bed, more or leſs thick, of rolled pieces of quartz and jaſper, of the ſize of an egg, and reſts on a bed of white clay of an unknown thickneſs. The bed of lignite is homogeneous, but foſſil vegetables are found in it in a good ſtate of preſervation; they are, 1, trunks of trees lying one on the other without order; the wood is black or reddiſh, generally compreſſed, it readily exfoliates by drying in the open air. Some of theſe belong to dicotyledonous trees, others are fragments of palms. Among theſe M. Coquebert-Montbret has found ſome that are filled with a number of ſmall round pyritic bodies reſembling grains of ſmall ſhot. Similar ſmall, but elongated round grains, reſembling a two-celled pod, have been found by Mr. Heim, in the lignite of Kalten-Nordheim. This wood burns very well, and even with a ſmall flame. 2. Woody fruits, of the ſize of a nut, and which are conſidered as belonging to a ſpecies of areca. The lignite of Cologne contains about twenty *per cent.* of aſhes rather alkaline and ferruginous. Its uſes are manifold; it is worked in open air with a ſimple ſpade, but in order to convey it with greater convenience, it is moiſtened and moulded in veſſels which give it the ſhape of a truncated cone. It is generally uſed as fuel in the neighbourhood of Cologne. It burns ſlowly but readily and without flame, like fungus tinder, giving a ſtrong heat and leaving very fine aſhes. The latter being conſidered as a very good manure, a part of the lignite is burnt on the ſpot where it is wrought, for the ſake of obtaining them.

The earth of Cologne is particularly employed for painting in diſtemper and even in oil painting. The Dutch uſe it to adulterate ſnuff, and if it is not added in too great a quantity it gives the ſnuff a deſirable fineneſs and ſoftneſs, and cannot be in the leaſt injurious. Faujas.

This lignite is ſaid to occur alſo in Heſſia, Bohemia, Saxony, Iceland, &c.; but as there has been a confuſion between this ſubſtance and the variety of ochre called *umber*, we cannot be certain that theſe indications of localities are referable to earthy lignite.

It may have been obſerved, from what has been ſaid on the ſituations peculiar to ſome varieties of lignite, that this foſſil combuſtible belongs to depoſitions of the moſt recent formation, ſince it is found only in alluvial ſand or clay; it ſeldom or never occurs in ſtony depoſitions, except in coarſe grained lime-ſtone and under baſalt. In the mountains of Heſſia called the Ringe Kuhle, ſeveral thick beds of lignite are ſeen reſting on ſandſtone, and ſeparated by beds of potters' clay and ſand.—(Mohs). On the ſea-ſhore near Calais, fragments of lignite have been found that were penetrated by very tranſparent globularly aggregated quartz cryſtals.

The air which circulates where lignite is wrought is generally bad.

From what has been ſaid it appears (our author concludes) that lignite is of a very different formation from that of coal; indeed, Mr. Voigt thinks that there is no tranſition between theſe two ſubſtances.

The firſt of Brongniart's varieties of lignite, is by Werner given as a ſub-ſpecies of his ſchwartz kohle, or black coal.

A variety not mentioned in the above account of lignite, but nearly related to the fibrous lignite No. 3, is the ſub-ſpecies of Werner's brown-coal, called *common brown-coal.* Its colour is light browniſh-black, paſſing into blackiſh-brown. It occurs maſſive. Its fragments are indeterminately angular, more or leſs ſharp-edged. It is found at Bovey, and ſeveral other places mentioned under the localities of fibrous lignite or bituminous wood.

LIGNON, in *Geography*, a town of France, in the department of the Marne; 9 miles S. of Vitry le François.

LIGNUM ALOES, or *Wood of Aloes*. See ALOES.

LIGNUM *Balſami*. See BALSAM.

LIGNUM *Campechianum*. See LOG-WOOD.

LIGNUM *Caſſiæ*. See CASSIA.

LIGNUM *Colubrinum*. See STRYCHNUS. Garcias tells us of the wonderful effects of this drug againſt the bites of venomous ſerpents, and deſcribes two kinds of the plant which produces it; one having leaves like the pomegranate, and the other like the peach-tree: theſe, he ſays, both grow in the iſland of Ceylon; and Acoſta mentions two other ſpecies of plants producing this wood, both different from either of thoſe deſcribed by Garcias, and both growing in Malabar. We have alſo accounts in the Geographus Nubienſis of another lignum colubrinum, different from theſe, growing in Ethiopia, and poſſeſſed of the ſame virtues againſt the bites of ſerpents as the others. This laſt is called in the Arabic *haud alhaic*, the plain verbal tranſlation of which is ſnake-wood, or lignum colubrinum. He tells us, that it has ſome reſemblance in form to pyrethrum, and that the wood is always contorted.

Alha cararha is another of its Arabic names, and this is the word by which Avicenna, and the other Arabian writers, interpret the *pyrethrum* of Dioſcorides; but it is not certain whether the ſimilitude of ſounds between two or more Arabic words, may not have occaſioned ſome confuſion or error here. Dicæarchus, in his fragment of mount Pelion, deſcribes the root of a tree growing there, which is not only a ſovereign remedy for the bites of ſerpents, but even deſtroys them by its ſmell. This is alſo a lignum colubrinum; but whether the ſame with any of the others, or different from them all, we have not deſcriptions enough to determine.

It appears, upon the whole, that little can be depended on in the accounts of the medicine called lignum colubrinum by any author, unleſs he has himſelf experimented what he relates, and deſcribed the plant which produces the drug; for much imaginary virtue has been at all times given to many things againſt the bitings of ſerpents, and the lignum colubrinum of one author is not the lignum colubrinum of another.

LIGNUM *Nephriticum*. See NEPHRITIC.

LIGNUM *Vitæ*, the wood of a genus of trees, called by botaniſts *thuya*; which ſee.

Lignum vitæ is much valued by turners: making extremely beautiful cups, bowls, boxes, and other curioſities.

Lignum vitæ is alſo a name given to guaiacum.

LIGNY, in *Geography*, a town of France, in the department of the Meuſe, and chief place of a canton, in the diſtrict of Bar-ſur-Ornein. The place contains 2815, and the canton 10,081 inhabitants, on a territory of 192½ kiliometres, in 19 communes.

LIGNY-*le-Chateau*, a town of France, in the department of the Yonne, and chief-place of a canton, in the diſtrict of Auxerre; 9 miles N.E. of Auxerre. The place contains 1249, and the canton 7301 inhabitants, on a territory of 182½ kiliometres, in 15 communes.

LIGOR, a town of Aſia, and once capital of a kingdom, now ſubject to Siam, ſituated on a river of the ſame name. Here the Dutch have a factory for tin, rice, and pepper. N. lat. 8° 18′. E. long. 100° 35′.

LIGOR, or *Tantalam*, an iſland at the entrance of the gulf of Siam, triangular in its figure, and about 130 miles in circuit. N. lat. 8° 10′. E. long. 100° 50′.

LIGUA, a river of Chili, which runs into the Pacific ocean, S. lat. 32°.—Alſo, a town of Chili, on this river; 72 miles N.N.E. of Valparaiſo.

LIGUEIT, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the diſtrict of Loches; 9 miles S.W. of Loches. The place contains 1998, and the canton 9756 inhabitants, on a territory of 327½ kiliometres, in 14 communes.

LIGUNY, a town of Samogitia; 44 miles E. of Miedniki.

LIGULA, a word uſed by medical writers in very different ſenſes. Some expreſs by it the clavicle, others the glottis; others uſe it as the name of a meaſure, for things either liquid or dry, being a quarter of a cyathus, equal to a forty-eighth part of a pint with us; others finally uſe it for a weight, leſs than half an ounce by two ſcruples, or ten ſcruples.

LIGULA, in *Natural Hiſtory*, a genus of the molluſca order of the claſs Vermes, according to the Linnæan ſyſtem: the character of this genus is body linear, equal, long; the fore part obtuſe, the hind part acute, with an impreſſed dorſal ſuture. There are only two ſpecies, *viz.* 1, the *inteſtinalis*, which has a clear white, and very narrow body, and which is found in the inteſtines of the merganſer and guillemot; about a foot long, and exactly reſembling a piece of tape. 2. The *abdominalis*, of which there are ſeveral varieties; the body is of a pale-aſh colour, and rather broad; it is found in the abdomen of the loche, gudgeon, tench, crucian, dace, bleak; cyprinus vimba, and bream. Theſe animals are found chiefly in the meſentery, emaciating the fiſh they infeſt, and making them grow deformed: when they eſcape from the body they penetrate through the ſkin; they are ſometimes ſolitary and ſometimes gregarious, about one-twentieth of an inch thick, and from ſix inches to five feet long.

LIGULATE Florets, in *Botany*, from *ligula*, a ſmall ſtrap, are ſuch as compoſe the radiant part of a daiſy. See Floret.

LIGURES, in *Ancient Geography*, a people of Gallia Ciſalpina, who occupied a territory along the ſea-coaſt, bounded on the N. by the Po, and ſeparated from Gaul by the Alps, and the oblique winding courſe of the Varus. Its eaſtern limit, at different periods, was the Macra, and the rapid Arnus. It comprehended the greater part of the diſtricts of Nice, Piedmont, Montferrat, Genoa, Modena, and Parma. This powerful nation was compoſed of many tribes, the boundaries of whoſe ſettlements cannot now be aſcertained with preciſion. Theſe tribes were the Vediantii, who inhabited a mountainous tract watered by the Varus, in which were Nicæa or Nice, and Cemenelium, or Cimia; the Intemelii, who occupied ſeveral places along the ſea-coaſt, *viz.* Intemelium, or Ventimiglia, Tropæa Auguſti, or Torbia, &c.; the Ingauni, whoſe capital was Albingaunum, or Albenga, and they alſo occupied the ſea-port towns of Vada Sabatia, or Vai, and Savo, now Savona; the Epanterii, who inhabited a mountainous diſtrict between the Vangienni and Ingauni; the Vangienni, who reſided near the declivity of Mons Veſulus, mount Viſo, and the ſources of the Po; the Statielli, who were cantoned at the bottom of the gulf of Genoa, in a hilly territory, that extended northward to the Tanarus; the cities and towns in this diſtrict, occupied by the Statielli, and other inferior tribes of the Ligures, were Genua or Genoa, Portus Delphinus, or Porto Fino, Segeſtra or Seſtri, Portus Veneris, or Porto Venere, and Luna; and the principal rivers of this diſtrict were the Macra and Boactes; the inland towns in the territory of the Statielli were Aquæ Statiellæ or Aqui, Ceba or Ceva, near the ſource of the Tanarus, Pollentia, Alba Pompeia, Aſta or Aſti, Bodincomagus or Induſtria on the Po, Forum Fulvii, ſurnamed Valentinum, on the Po, Cariſtum, Dertona or Tortona, and Iria or Voghiera. The Celelates and Cerdicates inhabited an inconſiderable diſtrict between the Trebia and the Po, now called Paveſan; their principal towns were Claſtidium, Chiaſtezo, and Litubium. The Briniates occupied a hilly tract not far from the ſea-coaſt, watered by the Boactes. The chief town of the Apuani was Apua, now Pontremoli, at the foot of the Apennines, near the ſource of the Macra. The Ananes, or Anamani were for ſome time eſtabliſhed in the territory now called Parma and Modena; the Lingones, in the northern part of Bologneſe, and in Ferrara; the Boii, in the S. part of the Bologneſe, at the foot of the Apennines; the Senones, in the eſtate of the church, along the coaſt of the Adriatic from Rimini to Ancona. To thoſe tribes belonged the following towns, *viz.* Parma, Brixellum or Berſello, Forum Novum or Fornovo, S.W. of Parma on the Tarus or Taro, Tanetum or Tanedo, between Parma and Modena, Calicaria, S. of the Po, Padinum or Buondena, N.W. of Forum Alieni, now Ferrara, Hadrianum or Ariano, Neronia above the mouth of the Po, and Spina at the mouth of the ſouth branch of the Po. The following towns were ſituated on Via Æmilia, between Parma and Arminium, *viz.* Tanetum already mentioned, Regium Lepidi or Reggio, Mutina or Modena, Bononia now Bologna, Claterna or Claterva, New Quaderno, Forum Cornelii or Imola, Faventia or Faenza, Forum Livii or Forli, Forum Popilii or Forlimpopoli. The inland ſettlements were Suſemontium, Aquinum, and Ravenna.

LIGURIA, a country of ancient Italy, which had on the W. a part of the Maritime Alps, and the river Varus; on the N. the Po; on the E. a part of Gallia Ciſpadana, and a ſmall portion of Etruria. In the time of Scylax, who wrote about the year 350 B.C., the Ligurians extended themſelves to the Arnus. See the preceding article.

LIGURIAN Republic. See Genoa.

LIGURINUS, in *Ornithology*, a name uſed by many authors for the bird more commonly known by the name of *ſpinus*, and called in England the *ſiſkin*.

LIGURIUS, in *Jewiſh Antiquity*, a precious ſtone on the high prieſt's breaſt-plate. It is called *leſchem* in Hebrew. Theophraſtus and Pliny deſcribe the ligurius to be a ſtone like a carbuncle, of a brightneſs ſparkling like fire.

The ligurius was the firſt ſtone in the third row upon the high prieſt's pectoral, and the name of God was inſcribed upon it. Ælian, De Animal. lib. iv. cap. 17. Pliny, lib. viii. cap. 38, and lib. xxxvii. cap. 3. Calm. Dict. Bibl. See Lyncurius *Lapis*.

LIGUSTICUM, in *Botany*, λιγυςικον of Dioſcorides, ſo called from Liguria, in Italy, its native country. The ancient plant evidently appears by the deſcription of this author to have been of the umbelliferous tribe, growing in mountainous ſituations, and of an aromatic pungent nature. So far it agrees with the Linnæan adaptation of the name; but among ſo intricate a tribe, who ſhall ſay that the *Liguſticum* of Linnæus is, or is not, the very ſame with that of Dioſcorides? Linn. Gen. 137. Schreb. 187. Willd. Sp. Pl. v. 1. 1424. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 309. Prodr. Fl. Græc. v. 1. 193. Ait. Hort. Kew. ed. 2. v. 2. 141. Juſſ. 222. Tourn. t. 171. Lamarck. Illuſtr. t. 198. Gærtn. t. 85. (Cicutaria; Tourn. t. 171. Danaa; Allion. Pedem. v. 2. 34. t. 63.)—Claſs and order, *Pentandria Digynia.* Nat. Ord. *Umbelliferæ.*

Gen. Ch. *General umbel* of numerous rays; *partial* ſimilar to it. *General involucrum* membranous, of about ſeven unequal leaves; *partial* of ſcarcely more than four, likewiſe membranous. *Perianth* of five teeth, ſcarcely diſcernible. *Cor. Univerſal* uniform; flowers all uſually fertile; partial of five equal, involute, flat, undivided petals, keeled inwardly. *Stam.* Filaments five, capillary, ſhorter than the corolla; anthers ſimple. *Piſt.* Germen inferior; ſtyles two, cloſe together; ſtigmas ſimple, obtuſe. *Peric.* Fruit oblong, angular, furrowed, ſeparable into two parts. *Seeds* two, oblong, ſmooth, marked with three elevated lines on the outer ſide, flat on the other.

Eſſ. Ch. Fruit oblong, with three ribs on each ſide. Flowers uniform. Petals involute, regular, undivided. Calyx of five teeth.

Obſ. Reichard obſerves that ſome male flowers are occaſionally intermixed. The fruit has not five grooves or furrows, but three elevated ribs, at each ſide.

1. L. *Leviſticum.* Common Lovage. Linn. Sp. Pl. 359. Woodv. Med. Bot. t. 190. Zorn. Ic. t. 233. Ehrh. Pl. Off. 393. (Leviſticum vulgare; Dod. Pempt. 311. Ger. em. 1008. Moriſ. Sect. 9. t. 3. f. 1.)—Leaves repeatedly compound; leaflets wedge-ſhaped at their baſe, unequally cut in the fore-part. Umbels many together. Native of the Ligurian Alps, whence it is taken for the λιγυςικον of Dioſcorides. In medico-botanical gardens it is preſerved on that account, but rarely elſewhere. The *root* is perennial, requiring a rich, rather moiſt ſoil. *Herb* five feet high, of a light, rather glaucous, green, ſmooth, ſtrongly aromatic

and acrid. *Leaves* bipinnate; leaflets about two or three inches long, and one broad, deeply cut. *Umbels* aggregate, ſtalked, their involucral leaves deflexed, whitiſh. *Flowers* ſmall, yellowiſh, coming out in May and June.

This plant, eſpecially the root, "whoſe flavour is leſs ungrateful (ſays Dr. Woodville) than the leaves," abounds with a yellowiſh fetid gum reſin. It was thought to be uſeful in removing obſtructions of various kinds, and even to aſſiſt delivery; but is now laid aſide.

2. L. *ſcoticum*. Scottiſh Lovage. Linn. Sp. Pl. 359. Engl. Bot. t. 1207. Fl. Dan. t. 207.—Leaves twice ternate, dilated, deeply ſerrated.—Native of ſea-ſhores in Sweden, Canada, Scotland; and recently diſcovered, as Mr. Winch informs us, at Dunſtonburgh caſtle, Northumberland. It is of much humbler growth than the firſt ſpecies, with twice ternate, broader and rounder *leaves*, ſhining beneath, rather ſerrated than cut. *Umbels* fewer, white with a reddiſh tinge. Mr. Lightfoot ſays this is eaten raw as a ſalad, or boiled as greens, in the iſle of Skye, where it is called *Siunas* or *Shunis*. The *root* is reckoned a good carminative, and an infuſion of the *leaves* in whey ſerves to purge calves.

3. L. *nodiflorum*. Nettle-leaved Lovage. Villars Dauph. v. 2. 608. t. 13. (Smyrnium nodiflorum; Allion. Pedem. v. 2. 21. t. 72. Angelica alpina, ad nodos florida; Tourn. Inſt. 313.)—Leaves twice or thrice ternate, dilated, taper-pointed, ſtrongly ſerrated. Umbels very numerous. Flower-ſtalks whorled, widely ſpreading.—Native of ſhady pine-foreſts on the Alps. *Stem* three or four feet high, ſolitary, with very numerous, whorled, divaricated, ſlender flower-ſtalks, and copious white *umbels*, whoſe involucral leaves are very few and narrow. Radical *leaf* ſolitary, large, ſmooth, twice or thrice ternate, or ſomewhat pinnate; the leaflets two or three inches long, ovate, taper-pointed, ſtrongly ſerrated in the manner of a nettle. Villars ſays the *root* is ſold at Lyons by the name of Bohemian Angelica, and has an aromatic flavour, leſs agreeable but more laſting than that of the true Angelica. It is diſtinct, as Villars well obſerves, from the *Angelica verticillaris* of Linnæus, and appears never to have come under his obſervation.

4. L. *peloponnenſe*. Hemlock-leaved Lovage. Linn. Syſt. Veg. ed. 14. 283. (L. peloponneſiacum; Linn. Sp. Pl. 360. Jacq. Auſtr. 33. append. t. 13. Seſeli peloponnenſe; Camer. Epit. 514. Matth. Valgr. v. 2. 112. Cicuta latifolia fœtidiſſima; Ger. em. 1062. Moriſ. Sect. 9. t. 6. f. 5.)—Leaves repeatedly pinnate; leaflets lanceolate, decurrent, taper-pointed, cut.—Native of mountainous woods in Carniola, Rhætia, Switzerland, and, as it ſhould ſeem, in the Peloponneſus; but Dr. Sibthorp did not find it. In gardens it is conſpicuous, but too much like hemlock to be cultivated for ornament. The *leaves* are very large, but finely cut, of a fine ſhining green, their ſegments numerous, crowded, remarkably decurrent and taper-pointed. *Umbels* white, one very large, with ſeveral ſmaller in whorls, accompanied by leaves, at the baſe of its ſtalk.

5. L. *auſtriacum*. Auſtrian Lovage. Jacq. Auſtr. t. 151. Allion. Pedem. v. 2. 15. t. 43. (L. n. 11; Gmel. Sib. v. 1. 196. t. 45.)—Leaves twice pinnate; leaflets wedge-ſhaped, decurrent, cut. Umbels leafy.—Native of the Alps of Auſtria, France, Italy, &c. Much like the laſt, but the *ſtem* is ſtouter; *umbels* larger and more leafy; *leaves* not ſo regularly pinnate or pinnatifid, nor ſo exactly decurrent, neither are they by far ſo taper-pointed.

6. L. *cornubienſe*. Corniſh Lovage. Linn. Sp. Pl. 359. Sm. Fl. Brit. 310. Ic. Pict. t. 11. Engl. Bot. t. 683. (L. aquilegifolium; Willd. n. 3. L. alterum belgarum; Lob. Ic. 786. Danaa aquilegifolia; Allion. Pedem. v. 2. 34. t. 63. Smyrnium luſitanicum minus, apii foliis; Tourn. Inſt. 316.)—Radical leaves twice compound, wedge-ſhaped, cut; ſtem-leaves ternate or ſimple, lanceolate and entire. Seeds ovate, tumid, obſcurely ribbed.—Native of buſhy ſtony places in Cornwall, Piedmont, and Portugal. Gathered by Dr. Sibthorp on mount Athos. It is perennial, and known from all the reſt by its principal compound *leaves* being all radical, the *ſtem* bearing only a few ternate or ſimple ones, quite undivided. The *umbels* are few and ſolitary. *Involucrum* ſcarcely membranous. *Seeds* remarkably tumid, ovate, black, obſcurely ribbed.—This plant, found in Cornwall in the time of Dillenius, who has figured it in his edition of Ray's *Synopſis*, t. 8, was long overlooked, and ſuppoſed to be loſt, till it was recovered about 25 years ago. Specimens ſent by Prof. Allioni to the writer of this have proved his *Danaa* to be the ſame. (See DANÆA.) Little did the late Prof. Sibthorp ſuſpect he had found ſo celebrated an Engliſh plant on mount Athos, which from his herbarium proves to be the caſe. Willdenow perhaps learnt from the Eſſay on Dorſiferous Ferns, Mem. de l'Acad. de Turin, v. 5. 420, that it was a *Liguſticum*, but having never ſeen it, either as the *Danaa* or the Corniſh Lovage, he has it twice in his Sp. Pl.

7. L. *pyrenæum*. Pyrenean Lovage. Willd. n. 8. Gouan. Illuſtr. 14, but not his t. 10. f. 2, which, though cited by himſelf, and copied by others, is *Thapſia garganica*. (L. alpinum perenne, ferulæ folio, floribus albis; Segu. Veron. v. 2. 41. t. 13.)—Leaves repeatedly compound; leaflets pinnatifid; ſegments nearly linear, awned. General involucrum ſlight. Seeds oblong, with membranous even ribs.—Native of the ſouth of France about the Pyrenées; alſo of mount Baldus, near Verona. The *leaves* are large, very finely divided, light green; their ſegments inclining to elliptical, decurrent, obtuſe, with a minute briſtle. *Stem* leafy. *Umbels* rather large; the general involucrum wanting, or deciduous; when preſent it is ſometimes of one three-cleft leaf. *Flowers* white, ſmall. *Fruit* elliptic-oblong, with ſtraight, pale, membranous ribs, and crowned with but a ſmall glandular floral receptacle. *Styles* reflexed.—Linnæus confounded this with his *Selinum Carvifolia*, but they appear to be ſufficiently different.

8. L. *multifidum*. Fine-leaved Lovage. (L. foliis triplicato-pinnatis, extremis lobulis breviter multifidis; Gmel. Sib. v. 1. 199. t. 46. Herb. Linn.)—Leaves thrice compound; ſegments linear, channelled, decurrent, pointed. Seeds ovate, with membranous, ſomewhat criſped, ribs.—Native of fields in the province of Iſet, in Siberia. Gmelin's ſpecimen is in the herbarium, but appears never to have been noticed in the works of Linnæus. The *root* is ſaid to have the taſte and ſhape of Carrot; it is as thick as the middle finger at the top, long and taper downward, yellowiſh without, white within. *Stem* two cubits or more in height, hollow, branched from about a third part of its height upward, the branches a foot long, ſomewhat leafy. Radical *leaves* with their long ſtalks about a ſpan long or more, finely thrice compounded, the ſegments uniformly narrow, acute, ſcarcely awned, channelled, entire, all decurrent, light green, ſmooth; ſtem-leaves much leſs divided, and ſmaller. *Umbels* not large, white; their general *involucrum* of about eight lanceolate, membranous-edged, leaves, and the partial ones are ſimilar. *Fruit* ſhort and roundiſh, with criſped wings, and a very large floral diſk or receptacle. *Styles* divaricated. *Stigmas* very obtuſe.

9. L. *candicans*. Pale Lovage. Ait. Hort. Kew. ed. 1. v. 1. 348. ed. 2. v. 2. 142.—Leaves repeatedly compound;

leaflets wedge-ſhaped, cut, ſmooth. General involucrum of two leaves, ſomewhat leafy. Ribs of the ſeeds membranous, ſmooth.—Introduced into Kew garden about the year 1780. It is ſaid to be a hardy perennial, flowering there in July and Auguſt; but its native country is unknown.

10. L. *peregrinum.* Parſley-leaved Lovage. Linn. Sp. Pl. 360. Jacq. Hort. Vind. v. 3. 13. t. 18.—Leaves repeatedly compound; leaflets three-cleft, wedge-ſhaped, cut. Seeds ovate, obtuſely ribbed. Umbels terminal.—Native of Portugal; gathered by the late M. Brouſſonet on the rock of Gibraltar, flowering in May. The *root* is biennal. The whole plant has the appearance, even the taſte and ſmell, of common parſley, but is in every part ſtouter and more rigid. There can be no doubt of its cloſe affinity to that plant; and great violence is offered to nature in referring one to *Liguſticum*, the other to *Apium*. Yet even the Bauhins diſtinguiſhed them as ſpecies.

11. L. *diffuſum.* Spreading Lovage. Roxburgh MSS. —Leaves twice compound; ſegments wedge-ſhaped, decurrent, three-toothed. Seeds ovate, ſtrongly ribbed. Umbels on lateral ſtalks, oppoſite to the leaves.—Native of the Eaſt Indies; given by Dr. Roxburgh, with the above name, to lord viſcount Valentia, to whom we are obliged for the ſpecimen. Its habit is ſo like the laſt, the *fruit* being of the ſame ſhape, though more ſtrongly ribbed, that it confirms the genus of that ſpecies. It differs in having ſmaller, leſs compounded, and blunter neatly toothed *leaves*, ſtrongly decurrent in their ſegments, and *umbels* on ſolitary, ſimple, lateral ſtalks. The *involucral* leaves are of a ſufficient number, lanceolate, long, narrow, pointed, with membranous edges. Ribs of the *ſeeds* prominent and ſomewhat criſped, not membranous.

12. L. *Meum.* Briſtle-leaved Lovage, Spignel, Meu, or Bald-money. Crantz. Auſtr. faſc. 3. 82. Roth. Germ. v. 1. 123. v. 2. 322. (Meum athamanticum; Jacq. Auſtr. v. 4. 2. t. 303. Sm. Fl. Brit. 308. Engl. Bot. t. 2249. Athamanta Meum; Linn. Sp. Pl. 353. Hudſ. 116. Œthuſa Meum; Linn. Syſt. Veg. ed. 14. 287. Willd. Sp. Pl. v. 1. 1447.)—Leaflets all in numerous, deep, briſtle-like ſegments.—Native of mountains in Italy, Spain, Germany, Switzerland and Britain, flowering in May. The propriety of referring it to this genus was hinted in Fl. Brit. and Crantz and Roth had previouſly ſo arranged it. Where ſo many different opinions have been ſtarted, the genus cannot be ſuppoſed very clear, but we venture to remove the plant hither. Its *root* is powerfully aromatic, with a flavour like melilot, of which the herb partakes; and an infuſion of the plant is ſaid to give cheeſe the taſte of the Swiſs *Chapziegar*. The finely divided *leaves* diſtinguiſh it readily. The *flowers* are white, with a bluſh occaſionally. *Fruit* oblong, often curved, coloured; its ribs ſtrong, not membranous, even, not criſped.

13. L. *balearicum.* Balearic Lovage. Linn. Mant. 218.—Radical leaves pinnate, rounded, ſerrated; the lower leaflets auricled: ſtem-leaves pinnate, narrow, cut. Fruit oblong.—Native of the Balearic iſlands, as well as of Italy and Spain. M. Brouſſonet gathered it at Gibraltar in May. Linnæus had this plant in the Upſal garden, but ſays it did not ripen ſeed, ſo that he was doubtful of the genus. It appears to us rather to belong to *Athamanta*. The young *fruit* is ſtriated rather than ribbed; the involucral leaves very ſlender, awl-ſhaped, not membranous. The *leaves* have ſomewhat of the aſpect of *Paſtinaca ſativa* in a wild ſtate. The *umbels* are wide, but ſlender, yellow.

14. L. *Gingidium.* New Zeeland Lovage. Forſt. Prod. 22. Willd. n. 12. (Gingidium montanum; Forſt. Gen. 21.)—Leaves pinnate; leaflets ovate, crenate; oblique and entire at the baſe.—Native of New Zeeland. Its aſpect is not unlike *Sium anguſtifolium*, but the *umbels* are axillary or terminal, and the *leaflets* very finely, rather ſharply, crenate, all broad and ovate.

15. L. *longifolium.* Long-leaved Lovage. Willd. n. 13. —"Leaves twice ternate; the radical ones doubly compounded; leaflets linear-lanceolate, entire."—Native of Siberia. Prof. Willdenow ſaw a dried ſpecimen. We know this ſpecies by his account only. He cites the *Peucedanum majus italicum* of Moriſon, ſect. 9. t. 15. f. 1, (at the bottom,) as ſeeming to agree with his plant.—The *leaflets* are ſtalked, linear, entire, tapering at each extremity, ſix or ſeven inches long, and three lines wide. General *involucrum* wanting; partial of many ſetaceous leaves.

We have, in the above view of the genus *Liguſticum*, added three ſpecies to his liſt, although we have reduced two of his into one.

LIGUSTICUM *Leviſticum*, or *Common Lovage*, in the *Materia Medica*. The odour of this plant is very ſtrong, and peculiarly ungrateful; its taſte is warm and aromatic. It abounds with a yellowiſh, gummy, reſinous juice, very much reſembling opoponax. Its virtues are ſuppoſed to be ſimilar to thoſe of angelica and maſter-wort in expelling flatulencies, exciting ſweat, and opening obſtructions; and it is therefore chiefly uſed in hyſterical diſorders and in uterine obſtructions. A teacup-ful of the juice with Rheniſh wine, or a decoction of the ſeeds with wine or mugwort water, was, by Foreſtus, ſaid to be a ſecret remedy of extraordinary efficacy in ſlow or laborious parturition. The leaves, eaten as ſalad, are accounted emmenagogue. The root, leſs ungrateful than the leaves, is ſaid to poſſeſs ſimilar virtues, and may be employed in powder. Woodv. Med. Bot.

LIGUSTICUM *Marmor*, in *Natural Hiſtory*, a name by which ſome authors have called the *Carrara marble*, the *marmor lunenſe* of the ancients. It is a fine white marble, harder than the Parian or ſtatuary kind, and uſed for tables, chimnies, &c. as the other for carving. See LUNENSE *Marmor*.

LIGUSTRUM, in *Botany*, a name found in Pliny and other Latin writers, by which the oriental Cypros (*Lawſonia inermis*) ſeems originally to have been intended, but which is now univerſally received for our Privet.—Linn. Gen. 9. Schreb. 12. Willd. Sp. Pl. v. 1. 41. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 12. Ait. Hort. Kew. ed. 2. v. 1. 19. Tournef. t. 367. Juſſ. 106. Lamarck Illuſtr. t. 7. Gærtn. t. 92.—Claſs and order, *Diandria Monogynia*. Nat. Ord. *Sepiariæ*, Linn. *Jaſmineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, very ſmall; mouth four-toothed, erect, obtuſe. *Cor.* of one petal, funnel-ſhaped; tube cylindrical, longer than the calyx; limb ſpreading, cut into four ovate ſegments. *Stam.* Filaments two, oppoſite, ſimple; anthers erect, almoſt as long as the corolla. *Piſt.* Germen ſuperior, roundiſh; ſtyle very ſhort, ſtigma cloven, obtuſe, thickiſh. *Peric.* Berry globoſe, ſmooth, ſingle-celled. *Seeds* four, convex on one ſide, angulated on the other.

Obſ. Gærtner more correctly deſcribes *Liguſtrum* as having a two-celled berry; the cells coated with a thin membrane, having two ſeeds in each cell.

Eſſ. Ch. Corolla four-cleft. Berry ſuperior, of two cells, with two ſeeds in each cell.

1. L. *vulgare.* Privet. Linn. Sp. Pl. 10. Engl. Bot. t. 764. Curt. Lond. faſc. 5. t. 1.—Leaves elliptic-lanceolate, obtuſe, with a little point.—Not uncommon in hedges and thickets where the ſoil is moiſt and gravelly, flowering in May and June, and ripening its berries in Auguſt.—This *ſhrub* riſes to the height of five or ſix feet. *Branches* wand-

like. *Leaves* oppoſite, nearly ſeſſile, dark green, ſmooth, lanceolate, (now and then elliptical,) entire, pointed, not acuminated, generally remaining through the winter. *Panicles* terminal, denſe. *Flowers* white, ſmelling diſagreeably. *Berries* dark purple, or blackiſh, very bitter, like the foliage and bark.

Privet is remarkable for thriving amidſt the ſmoky atmoſphere of towns, being frequently planted for hedges in gardens, for which purpoſe it is particularly eligible, ſince its foliage ſomewhat reſembles that of the myrtle, and in mild winters is almoſt evergreen. It was formerly known by the name of Print, or Prim-print, moſt probably from its neat and regular appearance when clipped and trimmed. The beſt mode of propagating this plant is by ſeed. It is eaten by the *Sphinx* Liguſtri, in its caterpillar ſtate, one of our fineſt native inſects. Curtis ſays that the berries are recommended in dyeing, colouring of wines, and as affording a purple colour to ſtain prints, though at the ſame time he remarks there are much better materials in common uſe for the ſame purpoſes.—This ſpecies is ſubject to variation with reſpect to its leaves, which are ſometimes variegated, and growing three at each joint. The berries have alſo been found white, or rather yellow. We ought not to omit mentioning that this fruit is one of the vegetable ſubſtances which has been ſuſpected to form a principal ingredient in the preſent popular gout medicine, the *eau medicinale d'Huſſon*.

2. L. *japonicum.* Broad-leaved Privet. Willd. n. 2. Thunb. Japon. 17. t. 1.—Leaves ovate, acuminate. Panicle divaricated.—A native of Japan, as its ſpecific name teſtifies; where it flowers in June and July, and ripens its fruit late in the autumn.—*Stem* eight or nine feet high, very much branched. *Branches* oppoſite, roundiſh, rugoſe, aſh-coloured, erect, rather ſpreading. *Leaves* oppoſite, on footſtalks, entire, with a deep furrow in their centre, green above, pale underneath, ſmooth, an inch broad, an inch and half long. *Footſtalks* round, furrowed on the upper ſide. *Flowers* in terminal ſpreading panicles. *Berry* ovate, ſmooth, the ſize of a pea.

3. L. *lucidum.* Chineſe Privet. Wax-tree. Ait. Hort. Kew. n. 2.—Leaves ovate-oblong, acuminate, ſhining above. Panicle greatly divaricated.—A native of China, and introduced into Kew garden by the Right Honourable ſir Joſeph Banks, K.B. in the year 1794. It flowers from July to September.—This *ſhrub* is only to be ſeen at the place above mentioned, where we are informed it makes a beautiful appearance, when covered with its copious white bloſſoms, in the open air. It is to be regretted that ſo deſirable a plant ſhould not be in general cultivation.

4. L. *ſinenſe.* Narrow-leaved Privet. Loureir. Cochinch. 19. Mart. Mill. Dict.—Leaves lanceolate, downy, panicles oblong, both lateral and terminal. Found near Canton in China.—This ſmall *tree*, according to Loureiro, grows to the height of about eight feet. *Branches* diffuſe, ſtraight. *Leaves* oppoſite, lanceolate, entire, downy, dark-green. *Flowers* white, ſmall, in oblong panicles. *Berry* very ſmall, roundiſh, of a brown colour.

LIGUSTRUM, in *Gardening*, comprehends a plant of the hardy deciduous and evergreen ſhrubby kind; of which the ſpecies cultivated is the common privet (L. vulgare). It is a ſhrub, uſually about ſix feet in height, branched, the bark of a greeniſh aſh-colour, irregularly ſprinkled with numerous prominent points; branches oppoſite, the young ones flexible and purpliſh; the leaves oppoſite, on very ſhort petioles, ſmooth on both ſides, perfectly entire, the lower ones at the bottoms of the ſmall branches leaſt: the panicle about two inches in length, cloſe and ſomewhat pyramidal; branches and pedicles appearing villoſe when magnified; the corolla white, but ſoon changing to a reddiſh-brown; the flowers are ſweet-ſcented; berry ſuperior, fleſhy, ſub-globular, ſhining, of ſo dark a purple as to ſeem black; it is found wild in moſt parts of Europe, &c. flowering in July, and the berries ripen in autumn.

Of theſe plants there are ſeveral varieties; as with the leaves in threes, and enlarged at the baſe; with ſilver-ſtriped leaves; with gold-ſtriped leaves, with white berries; and the evergreen or Italian privet, which riſes with a ſtronger ſtem, the branches leſs pliable, and grows more erect; the bark is of a lighter colour. The leaves much larger, ending in acute points, of a brighter green, and continue till they are thruſt off by the young leaves in the ſpring: the flowers are rather larger, and are not often ſucceeded by berries in this climate.

Method of Culture.—Theſe different plants are capable of being increaſed by ſeeds, layers, ſuckers, and cuttings; but the firſt method affords the beſt plants: the ſeeds ſhould be ſown in autumn, in a bed of common earth an inch deep, or in drills the ſame depth; but as they do not always grow freely the firſt year, they may be buried till next autumn, in pots of ſandy earth, in the ground, and then ſown as above: when the plants come up they ſhould be kept well weeded, and, when a year or two old, be planted out in nurſery rows, to remain two or three years, then removed where they are wanted to remain: the layers ſhould be laid down, from ſome of the pliable young branches, in the earth, in autumn or winter, when they will be rooted by the autumn following; then take them off from the ſtool, with their roots, and plant them in the nurſery for a year or two, or till of a proper ſize for the purpoſes they are intended: the ſuckers which ariſe annually from the roots ſhould be taken up in autumn, winter, or ſpring, with roots, and planted in the nurſery as above; the cuttings of the young ſhoots, eight or ten inches long, ſhould be planted in the autumn, in a ſhady border, where they will be properly rooted by the following autumn, when they may be planted out in nurſery rows, to acquire proper growth, in the manner directed above. The varieties with ſtriped leaves may be increaſed by budding, or inarching upon the plain ſort, or by laying down the branches; but they ſeldom ſhoot ſo faſt as to produce branches proper for this purpoſe; and being more tender, they ſhould have a dry ſoil and a warm ſituation: in a rich ſoil they ſoon loſe their variegation, and become plain. The Italian or evergreen ſort, which is now generally found in the nurſeries, is equally hardy with the other ſorts, and thrives in almoſt any ſituation: it is increaſed in the ſame manner; but as it ſeldom produces berries in this climate, they muſt be procured from the place of its native growth.

Theſe plants may be introduced in the ſhrubberies and other parts by way of variety, eſpecially the evergreen ſort.

But the chief uſe of the common ſort is to form ſuch hedges as are required in dividing gardens for ſhelter or ornament; yet the Italian or evergreen kind ſhould be preferred; it bears clipping well, is not liable to be diſfigured by inſects, and having only fibrous roots, it robs the ground leſs than almoſt any other ſhrub; it is one of the few plants that will thrive in the ſmoke of large towns, though it ſeldom produces any flowers in the cloſer parts after the firſt year: it alſo grows well under the drip of trees and in ſhade; the ſphinx liguſtri, or privet hawk moth, and phalena ſyringaria, feed on it in the caterpillar ſtate, and meloe veſicatorius, cantharides or bliſter beetle, is found on it. From the pulp of the berries a roſe-coloured pigment may be prepared; with which, by the addition of alum, wool and ſilk may be dyed of a good durable green: for which purpoſe they muſt be gathered as ſoon as they are ripe.

LIHONS, in *Geography*, a town of France, in the department of the Somme; 18 miles E. of Amiens. N. lat. 50° 15′. E. long. 2° 31′.

LIKA, a county and province of Dalmatia, or Auſtrian Croatia, bordering on the Adriatic, oppoſite to the iſland of Pago.

LIKAVA, a town and caſtle of Hungary; 5 miles N. of Roſenberg.

LIKE QUANTITIES, in *Algebra*, are thoſe which are expreſſed by the ſame letters, under the ſame power, or equally repeated in each quantity.

Thus $2b$ and $3b$, and $9ff$ and $3ff$, are like quantities; but $2b$ and $3bb$, and $9ff$ and $3fff$, are unlike ones, becauſe the quantities have not every where the ſame dimenſions, nor are the letters equally repeated.

LIKE *Signs*, or *Symbols*, are when both are affirmative, or both negative.

If one be affirmative, and the other negative, they are unlike ſigns.

Thus $+ 64d$ and $+ 5d$, have like ſigns; but $+ 9f$ and $- 7f$, have unlike ſigns.

LIKE *Figures*, in *Geometry*, are ſuch as have their angles equal, and the ſides about thoſe equal angles proportional. See SIMILAR.

LIKE *Arcs*, in the projection of the ſphere in plano, are parts of leſſer circles, containing an equal number of degrees with the correſponding arcs of greater ones.

LIKE *ſolid Figures*, are ſuch as are contained under like planes, equal in number.

LIKENAS, in *Geography*, a town of Sweden, in the province of Warmeland; 60 miles N.N.W. of Philipſtadt.

LI-KIANG-TOU, a city of China, of the firſt rank, in the province of Yun-nan, near the ſource of the river Yan-gong-kiang. This place is ſaid to be occupied by deſcendants of ſome ancient colonies of Chineſe; it has no other city under its juriſdiction, but the mountains that ſurround it ſeparate it from the land of the Lamas. Its mountains are ſaid to contain mines of gold. Amber and pine-apples are plentiful. The adjoining land is fertile, and is well watered. N. lat. 26° 52′. E. long. 100° 8′.

LILA, a town of Abyſſinia, on the coaſt of the Red ſea; 48 miles S.S.E. of Arkiko.

LILAC, in *Botany*, or rather *Lilâk*, the Turkiſh name for the Privet, *Liguſtrum vulgare*, according to Dr. Sibthorp; ſee Prodr. Fl. Græc. v. 1. 3. It is generally known in England as the appellation of the beautiful and popular *Syringa vulgaris*, which was introduced into our gardens, under the name of *Lilach*, or *Lillach*, in the time of queen Elizabeth; nor was this word by any means borrowed, as Dr. Johnſon ſuppoſes, from the *Lilas* of the French, though they have, doubtleſs, one common origin. The cloſe affinity and near reſemblance between the Privet and the Lilac, leave no room for wonder at their having the ſame name among the Turks. The common as well as the Perſian Lilac is cultivated by them, and the former at leaſt is found wild in ſome countries under their dominion. Matthiolus has given a fine cut of it (ſee *Lilac*, Matth. Valgr. v. 2. 575, 576.), from a drawing brought from Conſtantinople under this name; and it is curious to obſerve how the incorrect delineation of its fruit led him to miſtake it for a plant of the Piſtacia kind, and thence to ſuppoſe it a ſort of *Glans Unguentaria*, or *Ben* nut.

LILÆA, in *Ancient Geography*, a town which, according to Homer, was not far from the ſprings of the Cephiſſus, in the Phocide. When the Macedonians took poſſeſſion of it, Patron, one of the citizens, rouſed and armed the people, and cauſed them to evacuate it. In commemoration of this event, his fellow-citizens erected a ſtatue to his honour in the town of Delphi. In the time of Pauſanias it had a theatre, baths, and two temples, one in honour of Apollo, and another of Diana. The ſtatues were formed of Penthelic marble.

LILBURNE, JOHN, in *Biography*, famous for his exertions in the cauſe of liberty during the tyrannies of Charles I. and Cromwell, was born in the year 1618, of an ancient family, in the county of Durham. At an early age he was ſent, with very little education, to London, and put apprentice to Mr. Thomas Hewſon, of London-ſtone, a wholeſale clothier. He had, probably, imbibed thoſe principles for which he was afterwards diſtinguiſhed among his own relations in the country, and having a bold and intrepid mind, he was, from this period, involved in that perpetual ſeries of contention and ſuffering, of which we ſhall proceed to give a brief account. The firſt diſplay of his temper was exhibited in a complaint which he laid before the chamberlain of London, againſt his maſter for ill uſage. He carried his point, and obtained redreſs, and ever afterwards not only lived in peace with him, but he ſays, in his "Legal and Fundamental Liberties, &c." that he had in Mr. Hewſon "the trueſt friend that ever ſervant had of a maſter in the day of his trial." While he was in his apprenticeſhip he had much leiſure time, which he ſpent in reading the bible, the book of Martyrs, and the works of Luther, Calvin, Beza, &c. From theſe he unqueſtionably imbibed an enthuſiaſtic paſſion for encountering all dangers and ſufferings in the cauſe of truth. In 1636 he was introduced to the acquaintance of Dr. Baſtwick, at that time a priſoner in the Gate-houſe, whom he conſtantly viſited, and for whom he contracted ſuch a friendſhip and affection, that he could, he ſays, have readily laid down his life in his defence. He was ſoon engaged actively in the popular cauſe, and carried to Holland one of the doctor's anti-epiſcopal writings in order to get it printed. Shortly after his return he was apprehended, tried, and convicted in the ſtar-chamber court of printing and publiſhing libels and ſeditious books. At his examinations he refuſed to anſwer the interrogatories of his judges, and in every inſtance he juſtified and maintained the rights and privileges attached to his character as an Engliſhman. He was ſentenced on this occaſion to receive 500 laſhes, and then to be ſet in the pillory, which ſentence was executed with great ſeverity, the whipping being inflicted with knotted cords, as ordered by the bloody decree of old ſir Henry Vane. His ſpirit was not, however, ſubdued, for even on the pillory he uttered many invectives againſt the biſhops, and threw pamphlets from his pockets among the crowd. For this conduct he was remanded to priſon, and, according to his own account, endured a world of other unheard-of miſeries and barbarous cruelties for three years together. Though double-ironed, and in one of the worſt cells in the priſon, he contrived while there to get another libel printed and publiſhed. Such was the opinion held reſpecting his deſperate reſolution, that a fire having taken place near the cell in which he was locked up, he was ſuſpected of being the occaſion of it, for the ſake of obtaining his deliverance, and the other priſoners and neighbours joined in an application to have him removed, by which he obtained a more airy ſituation. On the meeting of the Long Parliament in 1640, he was allowed the liberties of the Fleet, an indulgence that enabled him to appear as a ringleader of an armed mob which aſſembled at Weſtminſter, and cried out for juſtice againſt the earl of Strafford, for which he was brought to the bar of the houſe of lords on a charge of treaſon, but diſmiſſed. In the following year the houſe of commons voted "That the ſentence of the ſtar-chamber againſt Mr. Lilburne was illegal, barbarous, bloody, and tyrannical, and that reparations ought to be given him for his impriſonment, ſufferings, and loſſes ſuſtained by that illegal ſentence." Neverthefeſs, he tells us, that he never received any remuneration, though he had been put to the expence of from 1000 to 1500*l.*, and had endured ſeven or eight impriſonments for nothing. When an army was raiſed by parliament, Lilburne entered into it as a volunteer, and, at the battle of Edge-hill, he acted as a captain of infantry. He behaved with diſtinguiſhed bravery at the battle of Brentford, where he was made priſoner, carried to Oxford, and arraigned on a charge of high-treaſon, but was ſaved by a declaration of parliament, threatening repriſals, and was ſoon after exchanged, was received with triumph by his party, and rewarded with 300*l.* as a compenſation for his ſufferings. Cromwell and Fairfax would willingly have employed him after they had new-modelled the army in 1645, and given him a high command; but his diſlike to the Preſbyterian church government would not permit him to ſerve the party then in power, and he laid down his ſword to reſume his pen, which he employed againſt Prynne, Lenthall, and other perſons. He was in conſequence committed to Newgate on a charge of ſeditious practices, but no bill being found againſt him, he was releaſed without trial. He next was brought before the houſe of lords for certain reflections caſt on the earl of Mancheſter, in a work entitled "The Juſt Man's Juſtification:" being examined upon interrogatories reſpecting the writing of that work, he not only refuſed to anſwer queſtions, but proteſted againſt their juriſdiction over him. He had ſtated the argument on this point, in full, in his "Legal and Fundamental Liberties of the People of England;" which he had maintained in the houſe, but which proved of no avail, as the houſe immediately made an order "that he be committed a cloſe priſoner in Newgate, and that none have acceſs to him but his keeper, until this court doth take farther order;" that is, ſaid Lilburne, "when they turn honeſt and juſt, which I confidently believe will never be." So much was he now regarded by the people as a champion of liberty, that a remonſtrance, ſigned by many thouſand names, was preſented to the houſe of commons in his behalf. This failing of effect, he continued to publiſh pamphlets, in which he diſplayed his grievances in ſuch bold and virulent language, that he rendered the leading men of all parties his enemies. It ſhould, however, be obſerved, that the leading men alluded to, were thoſe who were either adherents to the king, or thoſe who were attached to Cromwell; but Lilburne, perceiving that both parties were hoſtile to the liberties of the ſubject, did not ſcruple to oppoſe all their projects, which he ſuſpected, and juſtly too, would lead to the eſtabliſhment of a tyranny in ſome ſhape or other. He charged Cromwell with a deſign of uſurping the ſovereignty; and accuſed him and his relation Ireton of high treaſon, for which he was ordered to be tried as a libeller. At this period he had ſo many friends among the people, that the houſe of commons judged it proper to diſcharge him from priſon, and make an order for remunerating him for his ſufferings. At the time of the king's death, Lilburne was buſy in plans for ſettling a new model of government. Finding the leaders of the army reſolved to keep the power in their own hands, he oppoſed them with his uſual intrepidity, and maintained the right of the people to form a conſtitution for themſelves. So dangerous now did he appear to Cromwell and his council, that he was again committed to the Tower, and was brought to his trial for high treaſon before a ſpecial commiſſion. On this occaſion he defended himſelf with great firmneſs, never once ſhewing a diſpoſition to crouch to his proſecutors or his judges: he felt that he ſtood on firm ground, and was determined not to bend to the circumſtances of the times. The trial laſted many hours, and when the jury were about to retire to conſider their verdict, the foreman aſked permiſſion of the court to take a cup of ſack among them; to which the judge replied, it was impoſſible, they could have no manner of refreſhment while impannelled in a caſe of high treaſon. One of the court was willing they ſhould be indulged, but the chief juſtice ſaid he dare not permit it. Mr. Lilburne's jury retired for three quarters of an hour, and then brought in a verdict of Not Guilty: which, ſays the reporter of the trial, was received with unanimous plaudits from within and without, that continued without intermiſſion for more than half an hour. The judges, who ſeem to have ſtrained hard for a verdict of guilty, were abaſhed and confounded. Lilburne ſtood ſilent, affected and oppreſſed with the gratulations of his countrymen, unable to expreſs thoſe ſenſations which he unqueſtionably felt for the general intereſt which was taken in his cauſe. A medal was ſtruck of his head, with the following inſcription: "John Lilburne, ſaved by the power of the Lord and the integrity of his jury, who are judges of law as well as of fact." The names of the jurymen were given on the reverſe; names which muſt live ſo long as England is a free country. Mr. Hume, ſpeaking on this ſubject, and of thoſe who had uſurped the government, and of their unwillingneſs to truſt their cauſe to the deciſion of juries, choſen according to the ancient conſtitution of the country, ſays, "They had evidently ſeen in the trial of Lilburne what they could expect from juries. This man, the moſt turbulent, but the moſt upright and courageous of human kind, was tried for a tranſgreſſion of the new ſtatute of treaſons; but though he was plainly guilty, he was acquitted to the great joy of the people. Never did any eſtabliſhed power receive ſo ſtrong a declaration of its uſurpation and invalidity, and from no inſtitution, beſides the admirable one of juries, could be expected this magnanimous effort."

A new offence which he gave to parliament cauſed that body to paſs a ſentence of heavy fine and puniſhment againſt him, upon which he retired to Holland. Here he remained till the diſſolution of the Long Parliament, when he uſed all his intereſt to obtain a paſſport for his return to England, and not ſucceeding, he ventured, in June 1653, to come back without one. He was very ſoon apprehended and committed to Newgate, and being brought once more to trial, he defended himſelf on the plea of illegality in his ſentence of baniſhment, and was accordingly acquitted by his jury. The government, however, ordered him to be immediately ſent out of the kingdom, but giving ſecurity for his future quiet behaviour, he was ſuffered to remain. The nature of the ſecurity here referred to has excited ſome doubts in the hiſtorian; but the writer of the article in the Biographia Britannica, makes it appear highly probable, that Lilburne's brother Robert became ſecurity in this inſtance for his future peaceable demeanour. Having brought together the arguments in favour of this hypotheſis, the writer referred to ſays, "Laying then all theſe circumſtances together, can there be any reaſonable doubt who was the perſon that averted Cromwell's wrath againſt our author, and ſaved him from tranſportation, and after going through an uncommon variety of ſtorms, tempeſts, and ſhipwrecks, ſettling the weather-beaten veſſel in a peaceful and ſtill harbour; where, partly through a full conviction, that all poſſibility of ſucceſs in any farther ſtrugglings againſt his adverſary was cut off, and chiefly out of a religiouſly affectionate regard for his entirely beloved brother who ſtood reſponſible for him, he paſſed the remainder of his days in perfect tranquillity, equally undiſturbed by, and undiſturbing his triumphant competitor." John Lilburne now ſettled at Eltham, in Kent, joined the ſociety of quakers, and even preached at their meetings in Woolwich, and other adjacent places, till his death in 1657, at the early age of thirty-nine. He had a wife, who poſſeſſed the ſame undaunted ſpirit with that of her huſband, and was his faithful and affectionate helpmate in all his ſufferings. By Anthony Wood, Lilburne is ſtyled, "a great trouble-world in all the variety of government:" by other hiſtorians and biographers he has been repreſented to have been of ſo factious and quarrelſome a temper, that "if there were none living but him, John would be againſt Lilburne, and Lilburne againſt John." Such charges were brought againſt him by his contemporaries, and in his "Legal and Fundamental Liberties of the People of England," he has taken pains to rebut the calumnies of his adverſaries, and to ſhew that his hand was never lifted up but againſt tyranny and tyrants: and at the cloſe of that work he ſubſcribes himſelf "An honeſt and true bred free Engliſhman, that never in his life feared a tyrant, nor loved an oppreſſor." If it were Lilburne's misfortune to be a trouble to the exiſting governments under which he lived; it muſt be remembered that he vindicated the cauſe of his country in oppoſition to the arbitrary meaſures of Charles I. and the uſurpations of Oliver Cromwell; and however he might be regarded by his contemporaries, and miſrepreſented by party writers, poſterity muſt look to him with reſpect, and ſhould be thankful that ſuch a man exiſted, in times of peculiar difficulty, when the will of the few had well nigh ſuperſeded the authority of the law, and when every thing holy and excellent in our conſtitution muſt have been for ever loſt, but for the exertions of ſuch patriots as Lilburne. His efforts in the public cauſe were not more zealous than they were pure and diſintereſted. What he conceived to be juſtice and the public good, he purſued againſt all parties with an invincible ſpirit, and through a life of perſecution. He was, at the ſame time, a firm ſupporter of the laws of his country, which, in return, often ſupported him, and proved effectual barriers againſt arbitrary violence. Biog. Brit. Hume. Lilburne's Trial by Varax; and his Legal Fundamental Liberties of the People of England, revived, aſſerted, and vindicated.

LILEN, in *Geography*, a town of South America, in the province of Popayan; 15 miles S.W. of Cali.

LILESWARA, in *Hindoo Mythology*, a name of Siva, the regenerative power of the deity. (See SIVA.) It means Iſwara (or the lord) who gives delight, and was aſſumed with manhood, in one of the numerous metamorphoſes detailed in the Puranas, by this deity, who in this form became re-united to his ſpouſe Parvati, *giving delight* to her in her terreſtrial manifeſtation, under the name of Lileſwari. (See PARVATI.) The Puranas abound in this deſcription of incarnation of their male and female deities, which, thus veiled in allegory, are ſuppoſed to conceal hiſtorical and philoſophical facts. (See PURANA.) Mr. Wilford, in ſeveral of the volumes of the Aſiatic Reſearches, has purſued this allegorical maze with great induſtry. See more particularly vol. iii. vi. and viii. See alſo Hindu Pantheon, p. 389.

LILI, the name of one of the favourite remedies of Paracelſus, the baſis of which is antimony; but he has not given us the proceſs for preparing it.

LILIA, in *Botany*, a natural order of plants, ſo called from *Lilium*, the Lily, which is one of them. Tournefort, who underſtood this order in a wider ſenſe than more recent authors, denominated the plants which he referred to it, *liliacei*; Linnæus, and moſt others, call them *liliaceæ*.

The *lilia* conſtitute the fourteenth order in Juſſieu's ſyſtem, and the fourth of his third claſs. The eſſential characters of this claſs are "Cotyledon one. Stamens inſerted into the calyx or corolla." He gives its diſtinctions at length as follows.

"Calyx of one leaf, tubular or deeply divided, ſuperior or inferior, ſometimes naked, more generally attended by a ſheath containing one or many flowers, rarely by an involucrum reſembling an exterior calyx. Corolla none; for what is called corolla by Tournefort, Linnæus, and others, in the opinion of the writer (Juſſieu), is a real calyx. Stamens definite in number, rarely indefinite, inſerted either into the lower or the upper part of the calyx, oppoſite to its ſegments; the filaments ſeparate, rarely united; the anthers ſeparate, of two cells. In a few inſtances the germens are ſeveral and ſuperior; with as many ſtyles and ſtigmas, and the ſame number of ſingle-celled capſules, with one or many ſeeds, internally of two valves, which bear the ſeeds on their margins. In moſt caſes the germen is ſingle, ſuperior or inferior; ſtyle ſingle, rarely threefold, or wanting; ſtigma ſimple or divided; fruit pulpy or capſular, of three cells, with three ſeeds or many; ſometimes two of the cells are abortive, or there is only one of the ſeeds perfected. The ſeeds of the berries are affixed to the internal angle of each cell; in the capſules, uſually of three valves, they are inſerted here and there upon the edges of an elevated receptacle, conſtituting the partition, in the middle of each valve, and ſeparating along with it. The *corculum* is ſmall, in a large horny *albumen*."

The order of *lilia* is thus defined.

Calyx inferior, coloured, in ſix deep ſegments, uſually equal and regular. *Stamens* ſix, inſerted into the bottom of each ſegment. *Germen* ſimple, ſuperior; ſtyle one, rarely wanting; ſtigma in three diviſions. *Capſule* ſuperior, of three cells and three valves, with many ſeeds, which are ranged in a double row in each cell, and generally flat.

The *ſtem* is moſtly herbaceous. Radical *leaves* ſometimes ſheathing; the reſt ſeſſile, for the moſt part alternate, rarely whorled. *Flowers* either naked, or furniſhed with a ſheath, (*ſpatha*,) or accompanied by a leaf reſembling ſuch; often drooping, the ſtyle being longer than the ſtamens.

The genera are eight; *Tulipa*, *Erythronium*, *Glorioſa*, (for which laſt Juſſieu retains the name *Methonica*,) *Uvularia*, *Fritillaria*, *Imperialis* (the Crown Imperial, ſeparated from *Fritillaria*, becauſe its nectariferous cells are round inſtead of oblong), *Lilium*, and *Yucca*.

Linnæus calls his *lilia* the Patrician order, or Nobility of the vegetable kingdom, in his fanciful diſtribution of plants at the head of his *Syſtema Vegetabilium*. We may ſuppoſe that he had in view, in this inſtance, not only the analogies of the other orders, but eſpecially the text, ſo often quoted, "conſider the lilies of the field,—they toil not, neither do they ſpin," &c. in which theſe gorgeous plants ſeem more particularly indicated. The very ſpecies, which our Saviour had then perhaps before his eyes, is thought to have been the ſplendid *Amaryllis lutea*, with which the fields of Paleſtine are over-run at the end of autumn. Poſſibly this hint may be of uſe to biblical chronologiſts. The learned Olaus Celſius ſeems not to have adverted to this text, as alluding to any particular plant. Some have, without any reaſon, taken for granted that the Garden Tulip was meant; but that plant is not a native of Paleſtine.

The order of liliaceous plants is now receiving moſt magnificent illuſtration at Paris, in a work expreſsly deſtined to that purpoſe, by M. Redouté, of which five volumes in folio have reached us. The figures are printed in colours, in the modern French manner. The deſcriptions are in French. Many plants, not properly belonging to the ſame family, are admitted into this publication, as a few of the *Orchideæ*, and *Scitamineæ*, which, though they interfere with its oſtenſible deſignation, certainly do not leſſen its value, either as to beauty or utility.

LILIACEOUS Plants, in *Gardening*, all ſuch as reſemble thoſe of the lily kind, in their flowers having ſix regular petals, in the form of a lily; or three, or even one petal deeply divided into ſix ſegments, aſſuming a lily-flower form: they have not, however, all flowers ſo large as that of the lily, ſome being conſiderably ſmaller; and as the common lily has no calyx, ſo ſeveral of the liliaceous flowers are alſo deſtitute of a cup; and others have cups, which are principally of that ſort called a ſpathe. They may, therefore, be diſtinguiſhed into ſuch as have cups and ſuch as have not.

Thoſe with cups are all the different ſorts of the common lily: the tulip, all the kinds; fritillary, and crown imperial; hyacinth; ſtar of Bethlehem; baſtard ſtar of Bethlehem; tuberoſe; aſphodel; ſquill; hemerocallis, or daylily; anthericum, or ſpiderwort; aloe; yucca, or Adam's needle; glorioſa, or ſuperb lily, &c.

Thoſe with ſpathes or cups are the crocus; galanthus, or common ſnow-drop; leucoium, or great ſnow-drop; daffodil, narciſſus, and jonquil; crinum, or aſphodel lily; colchicum; iris, or flower-de-luce; hemanthus, or bloodflower; gladiolus, or ſword-lily; Virginia ſpider-wort; amaryllis, including the Guernſey lily, belladonna lily, and Jacobea lily, &c.; pancraticum lily, &c.

It may be noticed, that the greater part of theſe liliaceous plants of both kinds are bulbous-rooted: ſome, however, have tuberous, and ſome fibrous roots; and all of them are perennial in root, but annual in the ſtalk or ſtem.

Theſe are all ornamental garden-flowers, and moſt of them ſufficiently hardy to grow in the open ground; though a few are proper for the green-houſe and ſtove, as they require protection. See theſe different genera.

LILIAGO, in *Botany*. See Anthericum.

LILIASTRUM, the beautiful St. Bruno's lily. See Anthericum.

LILIENDAL, in *Geography*, a town of Sweden, in the province of Nyland; 15 miles N.E. of Borga. N. lat. 60° 23′. E. long. 26° 3′.

LILIENTHAL, a town of the duchy of Bremen, ſituated on the river Worp; 10 miles N.N.E. of Bremen.

LILIO-Asphodelus, in *Botany* See Crinum and Hemerocallis.

Lilio-*Fritillaria*. See Fritillaria.

Lilio-*Hyacinthus*. See Scilla.

Lilio-*Narciſſus*. See Amaryllis and Pancratium.

LILIUM appears to be a name of rather obſcure origin; ſome deduce it from the Greek λειριον, *a lily*, derived from λειος, *ſmooth, not rough*, alſo *handſome*, becauſe the plant is conſpicuous for the beauty of its flowers. It has moreover been called κρινον, from κριμνον, *duſt*, or *pollen*, becauſe the flowers ſeem in general to be ſprinkled with a powdery ſubſtance, from the abundance of their pollen. *Lilium* is adopted from Pliny and other Latin authors. Linn. Gen. 163. Schreb. 218. Willd. Sp. Pl. v. 2. 84. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 240. Tournef. t. 195. Juſſ. 49. Lamarck. Illuſtr. t. 246. Gærtn. t. 83.—Claſs and order, *Hexandria Monogynia.* Nat. Ord. *Coronariæ*, Linn. *Lilia*, Juſſ.

Gen. Ch. *Cal.* Perianth none. *Cor.* bell-ſhaped, narrower at the baſe; petals ſix, erect, lying over each other, obtuſely carinated at their backs, more expanding and broader upwards; their tips obtuſe, thick, reflexed. Nectary a longitudinal line, tubular, forming a channel in each petal from its baſe to the middle. *Stam.* Filaments ſix, awl-ſhaped, erect, ſhorter than the corolla; anthers oblong, incumbent. *Piſt.* Germen ſuperior, oblong, cylindrical, marked with ſix furrows; ſtyle cylindrical, the length of the corolla; ſtigma thickiſh, triangular. *Peric.* Capſule oblong, ſix-furrowed, hollow, triangular, and obtuſe at the top, of three cells and three valves; the valves connected by a network of fibres. *Seeds* numerous, incumbent in a double order, flat, outwardly ſemicircular.

Obſ. The nectary, in ſome ſpecies, is bearded, in others naked. In ſome the petals are totally revolute, in others not ſo.

Eſſ. Ch. Corolla of ſix petals, bell-ſhaped, each petal marked with a longitudinal nectary. Capſule with valves connected by a network of fibres.

Examples of this beautiful and fragrant genus are the following. The colour of their flowers is either white, yellow, or red. The fourteenth edition of Linnæus's *Syſtema Vegetabilium* compriſes ten ſpecies. Willdenow has ſixteen, though his firſt, *L. cordifolium*, belongs to another genus, which Mr. Saliſbury, in Tr. of Linn. Soc. v. 8. 11, has propoſed to call *Sauſſurea*. (See Hemerocallis.)

L. *candidum*. Common White Lily. Linn. Sp. Pl. 433. Sm. Prod. Fl. Græc. v. 1. 227. Curt. Mag. 278. Redouté Liliac. t. 199. Woodv. Med. Bot. t. 101. (L. album; Rudb. Elyſ. v. 2. 167.)—Leaves lanceolate, ſcattered, attenuated at the baſe. Corolla bell-ſhaped, ſmooth on the inſide.—This is the Κρινον of Dioſcorides, and Κρίνο of the modern Greeks. Great doubts exiſted reſpecting the native habitat of this well knowm and elegant plant, till Mr. Hawkins, the friend and companion of Dr. Sibthorp, found it growing wild in that truly claſſical and celebrated ſpot, the vale of Tempe. It flowers early in the ſummer, and has been cultivated in our gardens from time immemorial. *Root* a large ſcaly bulb, from which proceed many ſucculent fibres. *Stem* firm, upright, ſimple, uſually riſing to the height of about three feet. *Leaves* numerous, long, ſmooth, ſeſſile. *Flowers* large, white, in a cluſter at the top of the ſtem; the petals are of a beautiful ſhining white on their inſide, ridged, and not quite ſo tranſparent or luminous on their outſide.

Pliny and Ovid have each added their teſtimony to the general admiration in which this plant has been univerſally held. The former ſays, *Lilium Roſæ nobilitate proximum eſt.* The latter has thus poetically aſcribed its origin to the milk of Juno:

> " Dum puer Alcides Divæ vagus ubera ſuxit
> Junonis, dulci preſſa ſapore fuit;
> Ambroſiumque alto lac diſtillavit Olympo
> In terras fuſum Lilia pulchra dedit."

Both theſe flowers have furniſhed ancient and modern poets with their ſhare of metaphor; either ſingly

> " —— Vel mixta rubent ubi lilia multâ
> Alba roſâ; tales virgo dabat ore calores."
>
> Æn. l. xii. 68.

The flowers have a pleaſant ſweet ſmell, and were formerly uſed for medicinal purpoſes, particularly as an antiepileptic and anodyne. A water diſtilled from them was uſed as a coſmetic, and the "oleum liliorum" was ſuppoſed to poſſeſs anodyne and nervine powers: but the odorous matter of theſe flowers is very volatile, being totally diſſipated in drying, and wholly carried off in evaporation by rectified ſpirit as well as water; and though both menſtrua become impregnated with their agreeable odour by infuſion or diſtillation, yet no eſſential oil could be obtained from ſeveral pounds of the flowers. Hence the Edinburgh College now directs the uſe only of the roots, which are mucilaginous, and are chiefly employed, boiled with milk or water, in emollient and ſuppurating cataplaſms: it is not improbable, however, that the poultices formed of bread or farina, poſſeſs every beneficial quality aſcribed to thoſe of lily-root. Gerard recommends them internally in dropſies. For this purpoſe, bread was made of barley meal, with the juice of the roots, and conſtantly uſed for a month or ſix weeks; but Dr. Lewis obſerves, that there are inſtances of ſimilar cures by the uſe of common bread; and that probably, in one caſe as well as in the other, abſtinence from liquids was the remedy. Lewis Mat. Med. Woodv. Med. Bot.

L. *bulbiferum*. Bulb-bearing, or Orange Lily. Linn. Sp. Pl. 433. Jacq. Auſtr. t. 226.—Leaves linear-lanceolate, ſcattered. Corolla bell-ſhaped, erect, glandular and rough on the inſide, downy without.—A native of Italy, Auſtria, and North America. It flowers in June and July. *Bulb* compoſed of numerous thick, white, looſely imbricated ſcales. *Stem* upright, about a foot and half high, ſtriated and angular, ſmooth, or ſlightly hairy. *Upper leaves* ſpreading horizontally, having a roundiſh pale-green or purpliſh bulb at their baſe. *Flowers* large and handſome, of a beautiful red or orange colour, paler on the outſide, inodorous.

There are ſeveral varieties of this generally cultivated plant, of which the moſt common is that figured in Curt. Mag. t. 36, but the darker tinted one of Jacquin is handſomeſt, bearing more bulbs and fewer flowers.

L. *ſuperbum*. Superb Martagon Lily. Linn. Sp. Pl. 434. Curt. Mag. t. 936. Redouté Liliac. t. 103.—Lower leaves whorled, the reſt ſcattered. Flowers forming a branched pyramid, reflexed. Corolla revolute.—A native of North America, whence it was imported by Mr. Peter Collinſon in the year 1738. It flowers from June to Auguſt. Wild ſpecimens of this beautiful ſpecies are ſeldom found with above three or four flowers, but they may be brought, by careful cultivation, to bear from twelve to fifteen. *Bulb* white as ivory. *Stem* round, ſmooth and even, two or three feet in height, branched. *Flowers* large and handſome, one at the end of each branch, red or yellow with dark ſpots; their ſmell is diſagreeable.

One of the fineſt figures that can be exhibited of this or any other plant, may be ſeen in the ſecond number of Dr. Thornton's Illuſtration of the Linnæan Syſtem.

L. *philadelphicum*. Philadelphian Lily. Linn. Sp. Pl. 435. Curt. Mag. t. 519. Redouté Liliac. t. 104.—Leaves whorled. Flowers erect. Corolla bell-ſhaped; petals unguiculate.—Sent from Philadelphia by Mr. John Bartram in the year 1757. It flowers in July. *Bulbs* ſmall, white and ſcaly. *Stem* rather more than a foot high, bearing two elegant flowers at the ſummit. Petals red and yellow, ſpotted towards their baſe with darkiſh red or purple.

Among the moſt common ſpecies in the gardens are *L. chalcedonicum*, Curt. Mag. t. 30, which is the Scarlet Martagon, ſo remarkable for its fine colour; and *L. Martagon*, Curt. Mag. t. 893, the Purple Martagon, or Turk's Cap Lily; both are very hardy.—*L. tigrinum*, Curt. Mag. t. 1237, (*L. ſpecioſum*; Andr. Bot. Repoſ. t. 586.) is however perhaps the moſt ſhowy ſpecies of all. It was introduced from China, by ſir Joſeph Banks, in the year 1807, and is found to bear our climate if cultivated in a border of bog earth, flowering in Auguſt.

Lilium *Convallium*. See Convallaria.

Lilium, in *Gardening*, containing plants of the bulbous-rooted flowery perennial kind, of which the ſpecies uſually cultivated are the common white lily (L. candidum); the Cateſby's lily (L. Cateſbei); the bulb-bearing or orange lily (L. bulbiferum); the purple martagon lily, or Turk's cap (L. martagon); the pomponian lily (L. pomponium); the ſcarlet martagon lily (L. chalcedonicum); the great yellow martagon lily (L. ſuperbum); the Canada martagon lily (L. Canadenſe); the Kamtſchatka lily (L. Camſchatcenſe); and the Philadelphian martagon lily (L. Philadelphicum).

In the firſt ſort the principal varieties are, with ſtriped flowers, or with blotched purple flowers, or with variegated ſtriped leaves, or with yellow edged leaves, with double flowers, and with pendulous flowers. But the firſt of theſe varieties is now become common; the purple ſtain giving the flower a dull colour, the common white is generally preferred. The ſecond is chiefly valued for its appearance in winter and ſpring; for the leaves coming out early in the autumn, ſpreading themſelves flat on the ground, and being finely edged with a fine yellow band, make a pretty appearance during the winter and ſpring months, as it flowers earlier than the plain ſort. The third is of little value, as the flowers never open well unleſs they are covered with glaſſes; nor have they any of the rich odour of the common ſort. The fourth came originally from Conſtantinople; the ſtalk is much more ſlender; the leaves narrower, and fewer in number; the flowers not quite ſo large, and the petals more contracted at the baſe; they always hang downwards; the ſtalks are ſometimes very broad and flat, appearing as if two or three were joined together: when this happens, they ſuſtain from ſixty to one hundred flowers, and ſometimes more; this, however, is merely accidental, as the ſame root ſcarcely ever produces the ſame two years together, or in ſucceſſion.

The third ſort has varieties with double flowers, with variegated leaves, with ſmaller ſtems, and the bulb-bearing fiery lily, which ſeldom riſes more than half the height of the others; the leaves are narrower; the flowers ſmaller, and of a brighter flame-colour, few in number, and more erect: they come out a month before thoſe of the common ſort, and the ſtalks put out bulbs at moſt of the axils, which, if taken off when the ſtalks decay, and planted out, they readily produce new plants.

In reſpect to the ſub-varieties, they are the great broad-leafed, the many-flowered, the ſmall, and the hoary bulb-bearing lily.

The fourth kind varies with white flowers, with double flowers, with red flowers and hairy ſtalks, and with imperial divided ſtalks.

The fifth ſpecies has varieties with double red flowers, with white flowers, with double white flowers, with red ſpotted flowers, with white ſpotted flowers, with yellow ſpotted flowers, with early ſcarlet flowers, and the major ſcarlet pompony.

And the ſixth ſort, according to Mr. Curtis, varies in the number of flowers, from one to ſix, and the colour in ſome is of a blood-red; alſo, with deep ſcarlet flowers, with purple flowers, and with large bunches of flowers.

ſtolen goods, but the evidence being inſufficient to convict him he was acquitted. In 1659, he received a handſome gold chain and medal from the king of Sweden, on account of his having mentioned that monarch in his almanac for two ſucceſſive years with applauſe. On the reſtoration of Charles II. he was examined as to the perſon who decapitated the late king, and declared that it was cornet Joyce. On account of the part which it was known he had taken during the commonwealth, he was glad to ſue out a pardon under the great ſeal, which was granted him. In 1665, when the plague raged in London, he removed to Herſham. After the great fire of London in 1666, he was examined as to the perpetrators of the deed, but he was unable by his art to ſatisfy his employers. Shortly after this he adopted for a ſon a perſon named Henry Coley, a taylor by trade, and gave him the profits of his almanac. Lilly died at Herſham in 1681, when he was about ſeventy-nine years of age. His works were numerous, the titles of which are given in the Biog. Brit., and alſo in Hutton's Mathematical Dictionary: the chief of them are "Chriſtian Aſtrology;" "A Collection of Nativities;" "Obſervations on the Life and Death of Charles late King of England;" and "Annus Tenebroſus, or the Black Year."

LILLY *of Paracelſus*. See TINCTURE *of Metals*.

LILLY *Point*, in *Geography*, a place of America, in King William County, Virginia, in which is a poſt-office; 134 miles from Waſhington.

LILOAN, a town on the E. coaſt of the iſland of Sibu; N. lat. 10° 40′. E. long. 123° 45′.

LILY, WILLIAM, in *Biography*, a famous ſchoolmaſter and grammarian, was born at Odiham, in Hampſhire, about the year 1466. He was educated at Magdalen college, Oxford, where he took a degree, and then went on a pilgrimage to the Holy Land. On his return he purſued his ſtudies at Rhodes, which iſland, after the capture of Conſtantinople, was the reſidence of ſeveral learned men, under the protection of the knights, its poſſeſſors. Here he ſtudied, and made great progreſs in, the Greek language; but for farther improvement in it, and in the Latin tongue, he viſited Rome, and attended the lectures of the moſt celebrated profeſſors. He now returned to London, and opened a ſchool for the learned languages, rhetoric and poetry, which he taught on pure claſſical principles. In 1510, when dean Collet founded St. Paul's ſchool, he appointed Lily the firſt maſter, a ſtation which he occupied with ſingular utility for twelve years. He died of the plague in 1522, or 1523. Lily was much eſteemed by his contemporaries, as well for his moral character, as for his literary abilities. He was the author of ſeveral Latin poems and tracts, but is beſt known for the grammar that goes under his name, and is ſtill uſed in our public ſchools. This was not wholly of his own compoſition, having been aſſiſted in it by the labours of cardinal Wolſey and dean Collet. Biog. Brit.

LILY, GEORGE, eldeſt ſon of the preceding, was born in London, and educated at Magdalen college, Oxford, after which he was made canon of St. Paul's and prebendary of Canterbury. He was the firſt perſon who publiſhed an exact map of Britain: he died in 1559, and left behind ſeveral works of merit, as "Anglorum Regum Chronices Epitome;" "Regum Angliæ Genealogia;" "Catalogus ſive Series Pontificum et Cæſarum Romanorum," &c. He left likewiſe a MS. life of biſhop Fiſher, which is depoſited in the library of the Royal Society. Biog. Brit.

LILY, *Leſſer yellow water*. See MENYANTHES.

LILYBÆUM, now *Marſala*, in *Ancient Geography*, a town of Sicily, S. of Drepanum, and near the promontory of the ſame name, now called Cape Bocco. It was the principal fortreſs of the Carthaginians in Sicily, and the only city that reſiſted Pyrrhus when he paſſed into this iſland in the 475th year of Rome; but having been ineffectually beſieged for five years, it was ceded to the Romans after the victory of Lutatius, A. U. C. 511. The iſle Ægades, the modern Maretimo, which is oppoſite to Marſala, ſeems to be the key of that immenſe harbour. It is formed by rocks, little low iſlands, tongues of land, and ſand-banks, which break the waves on all ſides, and form a large ſemi-circle, within which the ſea is always calm. It was from this fort that the formidable fleet commanded by Scipio Africanus ſailed, when he ſet out for Africa in the ſecond Punic war, A.U.C. 548. The beauty of this harbour induced the Saracens to call it "Marſala," ſignifying, in their language, the "Port of God." The number of inhabitants at Marſala is eſtimated at 25,000. Of this famous port and impregnable city, the traces that remain are ſome few ruins of the ancient walls W. of the town, built with enormous maſſes of ſtone, which no machine, before the invention of cannon, could ſhake. In front of theſe walls were deep ditches, hewn out of the rock, ſome parts of which ſtill exiſt. Here is no longer any anchorage for ſhipping, and the port is only fit for the reception of ſmall barks. It was deſtroyed, as it is ſaid, by Don John of Auſtria, who being unable to defend it, would not leave it open to the Africans, who were only at the diſtance of 50 leagues. At preſent Marſala has only a ſmall road, to which veſſels reſort in order to load with tunny, and the aſhes of kali, which are made here in great abundance, and form the principal and almoſt ſole object of the commerce of the country. The merchants of Marſeilles come hither to purchaſe it for their ſoap manufactories.

LIMA, in *Geography*, an audience of Peru, erected in the year 1542, which contains within its juriſdiction one archbiſhopric and four biſhoprics; *viz.* thoſe of Truxillo, Guamanga, Cuzco, and Arequipa. The archbiſhopric of Lima comprehends 15 juriſdictions, *viz.* the circuit of Lima, Chancay, Santa, Canta, Canete, Ica, Piſco, and Naſca, which three places form one juriſdiction, Guarachia, Guanuco, Yauyos, Caxatambo, Sarma, Jouxa, Conchucos, Guyalas, and Guamalies. The dioceſe of Truxillo contains ſeven juriſdictions; that of Guamanga nine; that of Cuzco fourteen; and that of Arequipa ſix.

LIMA, a famous city of the audience of Lima, and capital of the vice-royalty of Peru. This city, called "Civdad de los Reyes," or the city of the kings, from its having been founded by Don Franciſco Pizarro, on the feaſt of the Epiphany, A. D. 1535, is ſituated in the ſpacious and delightful valley of Rimac, whence, by corruption, the name Lima is derived: Rimac being the appellation of an idol to which the native Indians uſed to offer ſacrifices, as the

Yncas alſo did, after they had extended their empire hither: and as it was ſuppoſed to return an anſwer to the prayers addreſſed to it, they called it, by way of diſtinction, Rimac, or he who ſpeaks. The ſituation of this city is peculiarly advantageous, as it is placed in the centre of a valley, the whole of which it commands. Towards the north, at a conſiderable diſtance, is the Cordillera, or chain of the Andes; whence ſome hills project into the valley, the neareſt of which, to the city, are thoſe of St. Chriſtopher, and Amancaes. A river of the ſame name waſhes the walls of Lima, over which is an elegant and ſpacious ſtone bridge, with a gate of beautiful architecture, that forms the entrance into the city, and leads to the grand ſquare, which is large, and finely ornamented. In the middle of it is a noble fountain of bronze, and ſuch objects, uſeful as well as ornamental, are not uncommon. The form of the city is triangular, the baſe, or longeſt ſide, extending along the banks of the river. Its length is 1920 toiſes, or ⅔ds of a league; and its greateſt breadth from N. to S., that is, from the bridge to the angle oppoſite to the baſe, is 1080 toiſes, or ⅖ths of a league. It is ſurrounded with a brick wall, flanked with 34 baſtions; and in its whole circumference it has ſeven gates and three poſterns. On the ſide of the river oppoſite to the city is a ſuburb, called St. Lazaro, which has lately increaſed; all its ſtreets, like thoſe of the city, are broad, parallel, and at right angles, forming ſquares of houſes; all well-paved, ſupplied from the river with ſtreams of water, arched over, ſo that they contribute to cleanlineſs and ſalubrity, without the leaſt inconveniency. The number of ſtreets is ſaid to be 355, and of houſes 3941. Towards the E. and W. parts of the city, within the walls, are many fruit and kitchen-gardens; and moſt of the principal houſes have gardens for amuſement, which are continually refreſhed with water by means of canals. The whole city is divided into five pariſhes, and abounds with churches, convents, nunneries, colleges, and charitable foundations, which it would be tedious to recount, and it has alſo a famous univerſity, founded in 1576. All the churches and chapels are large, and adorned with paintings and other decorations of great value. The viceroys of Peru uſually reſide at Lima, enjoying all the privileges of royalty, and, beſides aſſiſting at the courts of juſtice, and the councils relating both to the finances and war, give every day public audience to all ſorts of perſons; for which purpoſe, there are in the palace three very grand and ſpacious rooms. Under the viceroy there is a number of officers, and of tribunals for the tranſactions of the buſineſs of the city and audience. The Cabildo, or Ayuntamiento, that is, the municipal body of the city, enjoys particular privileges; and the revenue of the capital exceeds 36,000 dollars. Since 1786, there is alſo a judge of the police, aſſiſted by an able architect, and other officers.

Upon the whole, we may obſerve, without reciting particulars, that Lima is not only large, magnificent, and diſtinguiſhed as the capital of the kingdom, by the reſidence of the viceroy, and the ſuperior courts and offices, but that it has an acknowledged ſuperiority over the other cities in that part of the world, from the inſtitutions that are eſtabliſhed for the advancement of literature and the ſciences. It is a place where luxury prevails to a great degree; the malls are crowded with handſome carriages; the number of coaches and calaſhes being computed at 1400. Nevertheleſs, amuſements are rare, and literature is neglected. Little encouragement is given to publications of a kind moſt likely to intereſt the inhabitants of the city and its environs. The univerſity of St. Mark is conducted on the plan of the Spaniſh univerſities. The theatre is a neat building; but the exhibitions do not diſplay much taſte. Coffee-houſes only began to be opened in 1771. Cock-fighting is a favourite amuſement on Sundays and feſtivals; nor are bull-fights unknown.

The number of inhabitants in this city, according to the lateſt enumeration, amounts to 52,627; the monks and clergy being 1392; the nuns 1585; the Spaniards, in general, 17,215; with 3219 Indians, and 8960 negroes, the reſt being Meſtizos, and perſons of other caſts. The rich eccleſiaſtics, proprietors of entailed eſtates, military and civil officers, and phyſicians, advocates, attornies, and artizans, may amount to 19,000; the reſt being ſlaves or domeſtics. The want of occupation leads many of the females to vice; and the men are rather inclined to indolence and ſloth. The population has declined ſince the erection of the new vice-royalty of La Plata; and it is likely ſtill farther to decreaſe, notwithſtanding an influx of 1400 perſons of all ſexes and conditions, who annually arrive as a ſupply; not to mention the Spaniſh girls, who, from the province of Piura in the north, and Ica in the ſouth, come hither to diſpoſe of their charms either in marriage or love, thoſe provinces being celebrated for female beauty. All the inhabitants of Lima, from the higheſt to the loweſt, are fond of fine clothes, and they indulge their paſſion to great exceſs. The women's dreſs conſiſts of a pair of ſhoes, a chemiſe, a petticoat of dimity, an open petticoat, and a jacket, which, in ſummer, is of linen, and in winter of ſtuff, to which ſome add a mantelette. Women of the loweſt condition, whoſe whole ſtock of apparel conſiſts merely of two chemiſes and a petticoat, wear bracelets, roſaries, and ſmall gold images, about their necks and arms, to the value of fifty or ſixty crowns. The females are, in general, of a middling ſtature, handſome, genteel, of a very fair complexion, with beautiful hair, and enchanting luſtre, and dignity in their eyes. They are naturally gay, ſprightly, jocoſe, without levity, and remarkably fond of muſic. The temperature of the air at Lima is agreeable; and though the difference of the four ſeaſons is perceptible, they are all moderate, and none of them troubleſome. Spring begins towards the cloſe of the year, *i. e.* towards the end of November, or beginning of December; this is ſucceeded by ſummer, the heat of which is moderated by the ſouth winds: at the latter end of June, or beginning of July, the winter begins, and continues till November or December, the autumn intervening. As rain is ſeldom or never ſeen at Lima, the place is equally free from tempeſts, and the inhabitants are totally ſtrangers to thunder and lightning: there are, however, other inconveniences and evils to which they are obnoxious. In ſummer they are tormented with fleas, bugs, and moſquitoes; but the moſt dreadful calamity to which this country is ſubject is the recurrence of earthquakes, of which they have had ſeveral, which have almoſt ruined the city. Theſe have occurred in 1582, 1586, 1609, 1630, 1655, 1678, 1687, 1690, 1697, 1699, 1716, 1725, 1732, 1734, 1745, and 1746; the latter being the moſt tremendous and deſtructive. As the beſt ſecurity againſt earthquakes, they build their houſes moſtly of wood, and the walls of wattled oziers or canes, covered with clay, and painted. The diſtempers moſt common at Lima are malignant, intermittent, and catarrhous fevers, pleuriſies, and conſtipations; and theſe rage continually in the city. The ſmall-pox is alſo known here; and when it occurs proves fatal to many. The wealth of this city is chiefly derived from the mines in the provinces to the north and ſouth; but agriculture proſpers very much in the vicinity, and the fields ſupply food for a multitude of horſes and cattle. The fertility of the ſoil was very much improved in ancient times by the care of the Yncas, to cut and arrange trenches in ſuch a manner, as to conduct the water of the rivers to irrigate the ſoil; and when the Spaniards took poſſeſſion of the country, they purſued the ſame plan; thus they watered the ſpacious fields of wheat and barley, large meadows, plantations of ſugar canes, and olive trees, vineyards, and gardens of all kinds, which were rendered very productive. By the earthquake in 1687, the ſoil was ſo vitiated, that it became unfit for yielding wheat and barley; but after remaining 40 years in this ſtate of ſterility, it again ſo far recovered itſelf as in a conſiderable degree to become fit for grain as before. However, repeated earthquakes have been unfavourable. The fields in the neighbourhood of Lima are chiefly ſown with clover, of which there is a very great conſumption, as it is the common fodder for all beaſts, particularly mules and horſes, of which there is an inconceivable number. The bread at Lima is the beſt in all this part of America, both with regard to its colour and taſte. The mutton and beef are alſo very good; and here is alſo plenty of poultry, pork, and fiſh; which latter article is ſupplied by the Indians of the coaſt, from the bay of Callao, and the villages of Cherillo and Luria. The river of Lima, and the coaſts, furniſh anchovies and various ſorts of ſhell-fiſh. The wines at Lima are of different ſorts, white, red, and dark-red, and of each ſort ſome are peculiarly excellent. They are imported from the coaſts of Naſca, Piſco, Lucumba, and Chili, but the latter produces the beſt. That from Piſco has the greateſt ſale, and from the ſame place all the brandies uſed at Lima or exported are brought. Many of the dried fruits are brought from Chili, and by the trade carried on between the two kingdoms, Lima is ſupplied with all ſorts of fruits known in Spain. At Lima there are no fabrics nor manufactures of any kind. Lima owes much of its magnificence and ſplendour to its being the capital of Peru, and the general ſtaple of the kingdom. As it is the reſidence of the government and chief tribunals, it is alſo the common factory for commerce of every kind, and the centre of the products and manufactures of the other provinces, together with thoſe of Europe, brought over in the galleons or regiſter ſhips; and diſtributed from hence through the wide extent of theſe kingdoms. At the head of the commerce is the tribunal del Conſulado, which appoint commiſſaries to reſide in the other cities of its dependencies, extending through all Peru. The chief commerce of Lima is with Valparaiſo, Concepcion, and Coquimbo, in the kingdom of Chili; the iſle of Chiloe, and Arica, Ilo, and Piſco in the ſouth; towards the north with Truxillo, Pacaſmayo, and Payta, in the viceroyalty of Peru; with Guayaquil and Panama in the viceroyalty of New Granada; and with Realejo in Guatamala, and Acapulco, in Mexico. This trade is conducted by 10 ſhips, 11 merchant-frigates, 19 packet-boats, and a balandra, or ſmall tranſport-boat; amounting in all to 351,500 quintals of tonnage, navigated by 460 ſeamen. After the deſtruction of the ſea-port town of Callao by an earthquake in 1747 (ſee CALLAO), a new town or village was founded, at the diſtance of a quarter of a league, called "Ballaviſta." There is a fortreſs called "San Fernando," with a ſufficient garriſon to defend the bay, which in the S.W. is fenced by a barren iſland called "San Lorenzo." Here all the ſhips anchor about two leagues from Lima. The coaſts of Naſca and Piſco ſend to Lima wine, brandy, raiſins, olives, and oil; and the kingdom of Chili, wheat, flour, lard, leather, cordage, wines, dried fruits, and ſome gold. Every Monday, during the whole year, there is a fair at Callao, whither the traders or proprietors of commodities reſort from all parts; and the goods are carried, according to the directions of the buyers, on droves of mules kept for this purpoſe by the maſters of the warehouſes. Copper and tin in bars are brought from Coquimbo; from the mountains de Caxamarea and Chacapoyas, canvas made of cotton for ſails and other ſtuffs of that kind, and Cordovan leather and ſoap are made all over Valles, the valley in which Lima is ſituated. From the ſouthern provinces, as Plata, Oruro, Potoſi, and Cuzco, is ſent Vicuna wool, for making hats and ſome ſtuffs of a peculiar firmneſs. From Paraguay, the herb called by that name is ſent, of which there is a great conſumption. The produce of the ſales in the inland parts of the kingdom is ſent to Lima in bars of ſilver, and pignas, which are porous and light maſſes of ſilver, being an amalgam of mercury and duſt taken out of the mines. The ſilver is coined at the mint in this city. Lima has alſo its particular trade with the kingdoms both of North and South America. The moſt conſiderable commodity received from the former is ſnuff, which is brought from the Havannah to Mexico, and after having been there improved is forwarded to Lima, and conveyed from thence to the other provinces. There is no province in Peru, that does not tranſmit to Lima its products and manufactures; and ſupply itſelf from hence with the neceſſary commodities.

Lima alſo receives from the ports of New Spain, naphtha, tar, iron, and ſome indigo for dyeing. The kingdom of Terra Firma ſends to Lima, leaf-tobacco and pearls, which find here a good market, as no mulatto woman is without ſome ornament made of them. The ladies and women of all ranks have an ancient cuſtom of carrying in their mouths a "limpion," or cleanſer, of tobacco. The intention of theſe is, as their name imports, to keep the teeth clean. The limpions are ſmall rolls of tobacco, four inches long and nine lines in diameter, tied with a thread which they untwiſt as the limpion waſtes. One end of this they put into the mouth, and after chewing it for ſome time, rub the teeth with it, thus keeping them always clean and white. All the timber uſed in building houſes, refitting ſhips, or conſtructing ſmall barks at Callao, is brought from Guayaquil, together with the cacao. S. lat. 12° 2′ 31″. E. long. 282° 27′. See Juan and De Ulloa's Voyage to South America, and Eſtalla, cited by Pinkerton's Geography. For further particulars, ſee PERU.

LIMA, a river of Spain, which riſes in the province of Galicia, traverſes the province of Entre Duero e Minho, and runs into the Atlantic, two miles below Viana. N. lat. 41° 40′. W. long. 8° 30′.—Alſo, a town of Arabia, in the province of Oman, near the coaſt; 32 miles S.E. of Julfa.

LIMACHU, a river of Chili, which runs into the Pacific ocean, S. lat. 30° 25′.

LIMACIA, in *Botany*, ſo named by Loureiro, from *limax*, a ſnail, in alluſion to the ſpiral furrows on its nut.—Loureir. Cochinch. 620.—Claſs and order, *Diœcia Hexandria*. Nat. Ord. *Sarmentaceæ*, Linn. *Aſparagi*, Juſſ.

Gen. Ch. Male-flowers nearly terminal, crowded together. *Cal.* Perianth inferior, ſhort, of ſix acute leaves, the alternate ones ſmaller, arranged altogether horizontally in a triangle. *Cor.* Petals three, triangular, almoſt erect, longer than the calyx; nectary equal to the calyx, divided into ſix, roundiſh, concave, fleſhy ſegments. *Stam.* Filaments ſix, very ſhort, each placed upon a ſegment of the nectary, and altogether forming a triangle; anthers of two cells, roundiſh.—Female flowers axillary, in pairs, on a ſeparate plant. *Cal.* as in the male. *Cor.* Petals ſix, roundiſh, curved, unequal; nectary equal to the calyx, divided into ſix, turbinate, connivent ſegments. *Piſt.* Germen ſuperior, ſomewhat triangular; ſtyle none; ſtigmas three, many-cleft, ſpreading. *Peric.* Drupa fleſhy, rather kidney-ſhaped, containing a ſingle ſeed. *Nut* ſpirally furrowed like a ſcrew, the kernel ſimple.

Eſſ. Ch. Male, Calyx of ſix leaves. Corolla of three petals.—Female, Calyx of ſix leaves. Corolla of ſix petals. Stigmas three. Drupa kidney-ſhaped, ſpiral.

1. L. *ſcandens.* Cay Mè gà of the Cochinchineſe, and found in the woods of Cochinchina.—*Stem* ſhrubby, climbing, without tendrils, long, much branched. *Leaves* alternate, ovate-oblong, acuminate, entire, ſmooth. *Flowers,* both male and female, yellowiſh-green. *Drupa* ſmall, ſmooth, acid and eſculent.

LIMADASI, in *Geography,* a town of Curdiſtan, on an iſland in the lake Van.

LIMANDA, in *Ichthyology,* a name by which ſome authors have called the flat-fiſh, which we in Engliſh call the *dab,* the *paſſer aſper* of authors.

LIMARIA, a name given by Gaza and ſuch other writers to the thynnus or tunny-fiſh, called the *Spaniſh mackrel.*

LIMASOVA, in *Geography,* one of the ſmaller Philippine iſlands, near Leyta. N. lat. 10° 1′. E. long. 125° 2′.

LIMASSOL. See LIMESOL.

LIMATAMBA, a town of Peru, in the dioceſe of Cuzco; 25 miles W. of Cuzco.

LIMATURA *Martis Præparata.* See IRON.

LIMAX, in *Natural Hiſtory,* the ſlug or ſnail, a genus of the Vermes Molluſca, claſs and order, of which the character is;—Body oblong, creeping, with a fleſhy kind of ſhield above, and a longitudinal flat diſk beneath; aperture placed on the right ſide, within the ſhield; feelers four, ſituated above the mouth, with an eye at the tip of each of the larger ones.

This genus, of which there are fifteen ſpecies mentioned in the Syſtema Naturæ, comprehends thoſe animals that are commonly known by the name of ſlugs, or naked ſnails, which commit ſuch depredations in our fields and gardens, eſpecially in wet weather. Of the fifteen ſpecies ſix are common in our own country.

Species.

LEVIS. Body black, and almoſt without wrinkles. It is found among moſs late in the autumn, and is about half an inch long. The body is gloſſy, with undulate tranſverſe ſtriæ on the ſhield; narrower, and not ſo much wrinkled as the *ater,* which is the next mentioned.

ATER, or black ſlug; body black and furrowed with deep wrinkles. Of this ſpecies five varieties are enumerated: 1. The colour of this is deep black and pale beneath. 2. Black, with a pale greeniſh ridge down the back. 3. Black, beneath white; mouth yellowiſh. 4. Cheſnut-brown, beneath white; mouth yellowiſh. 5. Duſky-brown, with a yellowiſh mouth and ſtreak each ſide. This laſt is common in woods, meadows, fields, and gardens; and is from an inch and a half to five inches in length; it crawls very ſlowly, and leaves a ſlime upon whatever it paſſes over; feelers always black; the back is convex; the ſhield rough, with numerous dots; abdomen wrinkled.

ALBUS. This ſpecies, which is characterized by the whiteneſs of its body, contains four varieties. 1. The entirely white. 2. White edged with yellow. 3. White, with an orange margin and hind-head. 4. White, with black feelers; it inhabits woods and groves, and is from a quarter to half an inch in length.

RUFUS. Body, above pale rufous, beneath white; it inhabits ſhady damp places, and the bottom of hills, is about an inch and a half long; the body has neither ſpots nor belts; its feelers are larger than thoſe of the ater.

FLAVUS. Body amber-colour ſpotted with white, and is found in herbage.

MAXIMUS. Body cinereous, with or without ſpots; there are ſix varieties, *viz.* 1. Body immaculate; ſhield black-blue. 2. Shield ſpotted with black; body with black longitudinal ſtripes. 3. Shield and body ſpotted with black. 4. Body with five whitiſh ſtreaks, the lower one interrupted. 5. Body with white and cinereous wrinkles, and black ſpots in a double row. 6. Body edged with white; inhabits woods, gardens, and damp cellars; is from four to five inches long.

HYALINUS, takes its name from the colour of its body, which has a hyaline or glaſſy appearance; feelers obſolete, with a brown line reaching from the feelers to the ſhield; this is found in damp moſſy places, and is very deſtructive to the young ſhoots of kidney-beans; belly with numerous interrupted wrinkles.

AGRESTIS. Ruſtic ſlug; body whitiſh, with black feelers; this ſpecies is divided into four varieties, of which the 1, is entirely whitiſh, immaculate; 2, whitiſh, with a yellowiſh ſhield; 3, whitiſh, with a black head; 4, whitiſh, with a cinereous back; 5, whitiſh, with ſcattered black ſpecks.

The moſt curious of the above varieties is the ſecond, that with a yellowiſh ſhield, or that which is characterized by Müller, in his Hiſt. Verm. "Limax albidus clypeo flaveſcente," or by Gmelin, "Limax albus, clypeo flaveſcente;" it has been figured by Liſter, but more accurately, and with great care, in the fourth volume of the Linnæan Tranſactions, in which it is exhibited in a ſtate of repoſe, as it is ſeen in its progreſſive motion on the ground; and alſo as it is obſerved ſuſpended from the branch of a tree, &c. both with reſpect to its upper and under ſurfaces. This variety is denominated in our own language the *ſpinning ſlug,* and is commonly about three quarters of an inch long; it inhabits woods and other ſhady places. It was particularly noticed by Mr. Hoy, and deſcribed in the firſt volume of the Tranſactions of the Linnæan Society; at firſt he ſaw it ſuſpended from the branch of a fir tree, and was not aware that it was a living creature. It was hanging by a ſingle line or thread attached to its tail. This thread was in the upper part extremely fine, but near the animal it became thicker and broader, till at length it exactly correſponded with the tail. Its deſcent was at the rate of an inch in three minutes, a motion ſufficiently ſlow for the minuteſt obſervations. The line by which it deſcended was drawn from the ſlimy exudation gradually ſecreted from the pores that covered its whole body. Apparently there was much exertion required to produce a ſufficient ſupply of the liquid, and to force it towards the tail; it alternately drew back its head, and turned it as far as poſſible, firſt to one ſide, and then to the other, as if to preſs its ſides, and thus promote ſecretion.

In addition to Mr. Hoy's account, we ſhall give ſome farther particulars, taken from a curious paper by Dr. John Latham, in the fourth volume of the Linnæan Tranſactions; a work that contains abundance of intereſting matter, but which is too expenſive to have a very general circulation beyond the members of the ſociety. Speaking of the curious property belonging to the ſpinning ſlug, the doctor ſays, "that it is a cuſtom not unuſual for this ſpecies of limax to paſs from an height ſecurely to the ground, by means of a thread of its own conſtruction ſeems manifeſt; for, on my friend's (Colonel Montague, F.L.S.) putting one of them on the projecting frame of a window, it immediately crawled forwards till it came to the projecting angle, from whence, without attempting to fix itſelf by its fore parts to any thing, it became viſibly ſuſpended by a thread from its tail. When it had deſcended two feet, the colonel took it up by the thread, and carried it to a diſtant room; but trying to fix it afreſh, in order more accurately to obſerve its progreſs, the thread broke. He then put it on a frame about four feet from the ground; in a few minutes it was again ſuſpended, and obſerving by his watch, it deſcended at the rate of three inches and a half in a minute." After repeated trials, the colonel, by means of glaſſes, was enabled to aſcertain that the ſecretion, of which the thread was formed, was wholly from the under parts, and not from the back and ſides, both of which appeared nearly dry, nor did it proceed from any orifice in the tail. This creature ſeems quite ſenſible of its abilities, for it extended itſelf from the bottom of the frame, with its head downwards, till the tail became ſuſpended; and it was by means of an undulating motion of the belly that the flow of the viſcous ſecretion was produced towards the tail, but in doing this the belly was contracted, being furniſhed with numerous tranſverſe *rugæ;* at the ſame time the body and tentacula were fully extended, indicating no alarm whatever; the head was occaſionally moved from ſide to ſide, which gave ſeveral turns to the right or left, as the centre of gravity lay; but as it as frequently turned one way as the other, the thread was not in the leaſt twiſted. The thread, on firſt leaving the tail, was five times as broad as it was at the eighth of an inch diſtant therefrom, but afterwards ſeemed of an equal ſize, and conſiderably ſmaller than the fineſt human hair. When a portion of this thread was placed under a microſcope, it appeared contracted; it was pellucid and elaſtic. By another writer on this ſubject we are told, that by the application of the microſcope, the ſlimy humour will be ſeen to come out inſenſibly from the glandular pores of the ſkin, like clear and minute points; theſe, by continuing a gentle preſſure on the ſkin, will become ſmall drops, and in the end form a conſiderable collection of matter. It may be alſo obſerved, that colonel Montague found ſeveral individuals of this variety that he could not induce to ſpin, and, as if ſenſible of their inability ſo to do, readily turned back when approaching the projected edge; while others at once let themſelves down without heſitation; ſo that it might be known by their motion, when near the brink of the precipice, whether they were endued with the faculty or not. After theſe animals have ſpun for ſome time, their ſpinning power ſeems to be for a while loſt, but in all thoſe on which experiments have been made, it has been recovered again by keeping them for a few hours among wet moſs.

The fifth variety above-mentioned, or that with ſcattered black ſpecks, is found in gardens, paſtures, and groves, from May till the end of the year, and is the animal which has been recommended to be ſwallowed by conſumptive perſons. It is about half an inch in length, and when touched it ſticks to the fingers as if dead.

Cinctus. This ſpecies is yellowiſh, with a cinereous belt on the ſhield and body; it is commonly found in groves, and is about two inches long; body without ſpots, and beneath it is white.

Marginatus. This is cinereous; ſhield with a duſky ſtreak on each ſide: the body is of a pale blueiſh colour; it is found on the beech; back with a white ridge, each ſide of which is blueiſh-aſh; abdomen ſometimes ſpotted black.

Reticulatus. Brown, with black dots on the ſhield and lines on the body; it inhabits gardens in Denmark and Germany; it is an inch and a half long.

Aureus. Yellow, immaculate, with black feelers; it inhabits the groves of Denmark and Norway, is about half an inch long. The body beneath is white, with a black line between the feelers.

Fuscus. This is of a reddiſh hue, with a blackiſh lateral line and back.

Tenellus. Greeniſh, with black head and feelers; is found, early in the ſpring, in hollows of woods filled with dry leaves; about an inch long; the ſhield whitiſh with a yellowiſh caſt.

Lanceolatus. Linear-lanceolate and very ſharp at each end; the margin ſurrounded with a membranaceous border; without tentacula or feelers; found on the coaſt of Cornwall.

Limax *Marinus*, in *Zoology*, a name given by ſome to the *lipparis*, or, as it is commonly termed in Engliſh, the *ſea-ſnail*, caught in plenty at the mouths of rivers in Yorkſhire, and ſome other places. See Cylindrus.

LIMAY, in *Geography*, a town of France, in the department of the Seine and Oiſe, and chief place of a canton, in the diſtrict of Mantes; ſituated on the Seine, oppoſite to Mantes. The place contains 1520, and the canton 9881 inhabitants, on a territory of 137½ kiliometres, in 17 communes.

LIMB, in *Anatomy*, is uſed to denote certain parts of the human body, proceeding from the trunk. See Extremities.

The limbs, as well as the life of a man, are of ſuch high value in the eſtimation of the law of England, that it pardons even homicide, if committed *ſe defendendo*, or in order to preſerve them.

Limbs, *Amputation of*, in *Surgery*. See Amputation.

Limbs, *Artificial*. Under this denomination, ſurgical writers ſpeak of the various machines and contrivances which have been invented for ſupplying the place, and in ſome meaſure executing the office, of limbs which are naturally imperfect or wanting, or which have been amputated, or otherwiſe loſt. Anciently, it was as much the duty of the ſurgeon to provide his patient with a wooden leg after amputation, as to cut off the member, which endangered life and could not be preſerved. At preſent, however, the buſineſs of furniſhing artificial limbs is left almoſt entirely to the mechanic, though it cannot be denied, that the attention of a judicious ſurgeon will often be well beſtowed in taking care, that the preſſure of ſuch machines is contrived to fall as little as poſſible upon that part of a ſtump which is moſt tender, and inclined to ulcerate. The end of a thigh-ſtump, indeed, can ill bear the effects of preſſure, and in this caſe, it is uſual to make the thigh part of the wooden member in the form of a conical box, which is calculated to receive the ſtump, and at the ſame time not allow the end of the bone to meet with any material reſiſtance below. The preſſure partly falls on the ſides of the remaining portion of the thigh, and partly on the pelvis, round which a ſtrap proceeds from the upper part of the machine. The makers of artificial limbs in this metropolis, however, have in general brought their buſineſs to great perfection, and ſuch patients as can afford it, may be accommodated with contrivances, which, without being heavy and cumberſome, bear a great reſemblance to the natural limb. Artificial hands and arms may alſo be procured, which have moveable fingers, and by the ingenuity of the mechaniſm, may be made to perform many little uſeful offices in graſping and holding things.

Limbs, *Diſlocations of*. See Luxation.

Limbs, *Fractures of.* See Fracture.

Limb, *Limbus*, the outermoſt border, or graduated edge, of an aſtrolabe, quadrant, or the like mathematical inſtrument.

The word is alſo uſed for the primitive circle in any projection of the ſphere in plano.

Limb alſo ſignifies the outermoſt border or edge of the ſun or moon, when the middle or diſk is hid in an eclipſe of either luminary.

Aſtronomers obſerve the lower and upper limb of the ſun in order to find out its true height, which is that of the centre.

Limb is alſo uſed, among *Botaniſts*, for the outer edge or border of plants, their leaves and flowers. See Petal.

LIMBÉ, in *Geography*, an iſland in the Eaſt Indian ſea, about 12 miles long, and 3 broad, near the E. coaſt of Celebes. N. lat. 1° 18'. E. long. 125° 10'.—Alſo, a ſmall town or village in the N.W. part of the iſland of St. Domingo; ſeven leagues W. by S. of cape François.

LIMBECK. See Alembic.

LIMBERG, in *Geography*, a town of the duchy of Stiria; 12 miles S. of Voitſberg.

LIMBERS, in *Artillery*, a ſort of advanced train joined to the carriage of a cannon, upon a march. See Carriage.

Limber-*holes*, in a *Ship*, little ſquare holes cut through her floor-timbers, ſerving to let the water to the well of the pump, which otherwiſe would lie between thoſe timbers, where the keel rope runs.

Every floor-timber has two limber-holes cut through it; *viz.* one on each ſide of the keelſon.

Limber *boards*, are ſhort pieces of plank, which form a part of the cieling or lining of a ſhip's floor, cloſe to the keelſon, and immediately above the limbers. They are occaſionally removed, in order to examine and clear the limber-holes.

Limber-*rope*, is a long rope, frequently retained in the limber-holes of a ſhip, and communicating from one to another, in order to clear them, by pulling the rope backwards and forwards, ſo as to looſen the ſand or dirt by which they may occaſionally be choaked.

LIMBEUO, in *Geography*, a town on the E. coaſt of the iſland of Celebes. N. lat. 0° 18'. E. long. 123° 18'.

LIMBOBARYA, a town of Bengal; 30 miles N.W. of Nattore.

LIMBORCH, Philip, in *Biography*, a celebrated Dutch divine, was born at Amſterdam in the year 1633. He was educated among the Remonſtrants, and had for his inſtructors among others, Barleius, and Gerard Voſſius. Having completed the uſual courſes of learning, in ethics, philoſophy, and the languages, he ſtudied theology under Curcellæus, the ſucceſſor of Epiſcopius, in the profeſſorſhip of that faculty, among the Remonſtrants at Amſterdam. Afterwards he went to Utrecht, where he attended the lectures of Gilbert Voetius, and other celebrated divines. In 1654 he undertook the office of miniſter at Haerlem, from whence he removed to Gouda. In 1660 he publiſhed an excellent collection of the correſpondence of learned and celebrated men, under the title of "Epiſtolæ præſtantium, et eruditorum virorum," 8vo. In 1684 and 1704 he publiſhed new editions of it, greatly enlarged, in folio. In this collection, almoſt the entire hiſtory of the affairs of the Remonſtrants may be traced from the time of Arminius down to the ſynod of Dort. In 1661 he publiſhed, in the form of a dialogue, a treatiſe in defence of toleration, which was exceedingly well received by the friends of liberty. In 1667 he undertook the paſtoral charge of the church at Amſterdam, and in the following year he was appointed divinity profeſſor. From this period he wholly devoted his ſtudies to the enquiries connected with his new office, and acquired a high reputation by the manner in which he performed its duties. In the year 1686 he publiſhed his ſyſtem of theology, under the title of "Theologia Chriſtiana ad Praxim Pietatis ac Promotionem Pacis Chriſtianæ unice directa." It paſſed very quickly through four editions. In this ſame year Limborch had a diſpute with Orobio, a Spaniſh Jew, who had eſcaped from the priſon of the Inquiſition, and ſoon after he publiſhed the ſubſtance of it in a treatiſe, entitled "Collatio Amica de Veritate Religionis Chriſtianæ, cum erudito Judæo." This treatiſe very ſatisfactorily repels the objections which any conſiſtent believer in the Old Teſtament can advance againſt the New. He obtained, in 1692, "The Book of Sentences of the Inquiſition of Tholouſe from 1307 to 1313," which he publiſhed, and prefixed to it a hiſtory of that horrible and bloody tribunal drawn from the writings of the inquiſitors themſelves. The title of it is "Hiſtoria Inquiſitionis; cui ſubjungitur Liber ſententiarum Inquiſitionis Tholoſanæ, ab anno 1307 ad 1313," 4to. This hiſtory is pronounced, by Mr. Locke, to be a work abſolutely perfect in its kind; it was tranſlated by Dr. Samuel Chandler into Engliſh, in two volumes 4to. with additions by the editor, by Anthony Collins, eſq. and by the author. Dr. Chandler prefixed to his edition an introduction, concerning the riſe and progreſs of perſecution. In 1694 he converted a young woman to Chriſtianity who had been drawn over to the Jewiſh religion by a perſon of whom ſhe had learned the Hebrew language. In 1711 Limborch publiſhed his valuable "Commentarius in Acta Apoſtolorum et in Epiſtolas ad Romanos, et ad Hebræos." He died in the month of April 1712, in the ſeventy-ninth year of his age. A funeral oration was delivered on the occaſion by Le Clerc, who, among other things, ſays, "He was, above all things, animated with the love of truth, and was indefatigable in ſearching for it, day and night, in the ſacred ſcriptures and the beſt expoſitors, and whenever he found it, he adhered to it inflexibly. His piety was pure and ardent, untinctured by ſuperſtition, or any notions diſhonourable to the benevolence of the Deity. As a preacher he was methodical, argumentative, and ſolid rather than eloquent; and ſo invariably was he governed by candour, moderation, and prudence, that he never gave offence to any one. In his inſtructions from his profeſſional chair, he was diſtinguiſhed by the greateſt perſpicuity, and the moſt exact order; to which his memory, which retained whatever he had written, no doubt greatly contributed. His behaviour towards all who had the happineſs of being acquainted with him, was ſo affable, kind, and conciliating, that they ſaw him with delight, and regretted, when they could no longer enjoy his converſation." Gen. Biog. Moreri.

LIMBOURG, John Philip de, a phyſician at Spa, who obtained a great reputation by his knowledge of the properties of the mineral waters, and by the ſucceſs with which he preſcribed them in many obſtinate diſeaſes, which had reſiſted other remedies. He reſided at Spa during the ſeaſon of drinking the waters. He publiſhed ſeveral works, the principal of which detail the reſult of his obſervations on their properties and uſes; *viz.* "Diſſertation ſur les Eaux de Spa, ſoutenue à Leyde, le 7 Août, 1736, &c." Liege, 1749, 12mo. "Traité des Eaux Minerales de Spa," Leyden, 1754, 12mo. "Diſſertations ſur les Bains d'Eau ſimple, tant par immerſion, qu'en douches et en vapeurs," Liege 1757, 12mo. "Caractères des Médecins, ou l'idée de ce qu'ils ſont communément, et celle de ce qu'ils devroient être, &c." ibid. 1760, 12mo. "Diſſertation ſur les Affinités chymiques, qui a remporté le prix de Phyſique de l'an 1758, au jugement de l'Académie de Rouen," ibid. 1761, 12mo. "Nouveaux Amuſemens des Eaux Minerales de Spa," ibid. 1763, 12mo. "Diſſertation ſur les douleurs vagues, connues ſous le nom de goutte vague, et de rheumatiſme goutteux, &c.;" a prize eſſay, ibid. 1763. "Recueil des Effets des Eaux Minerales de Spa, de l'an 1764; avec des remarques ſur le ſyſtème de M. Lucas ſur les mêmes eaux minerales," ibid. 1765. Eloy. Dict.

LIMBOURG, *Duchy of*, in *Geography*, before the revolution, was a province of the Netherlands, bounded on the N. by the duchy of Juliers, on the E. by the electorate of Cologne and duchy of Juliers, and on the S. and W. by the biſhopric of Liege; about 30 miles long and 24 broad; but now annexed to France, and forming part of the department of the Ourte. It affords good arable ground, and abounds with a fine breed of cattle. Near the town of Limbourg are found mines of iron, lead, and calamine.

LIMBOURG, late capital of the above-mentioned duchy, now a town of France, in the department of the Ourte, and chief place of a canton, in the diſtrict of Malmédy; ſituated near the river Waze, in a fertile country, on a pleaſant mountain. It was formerly fortified in a regular manner, and had a caſtle, built on a rock, and defended by towers and baſtions, conſtructed of free-ſtone. When it was ceded to the houſe of Auſtria by the treaty of Baden, the fortifications were deſtroyed. Near it are quarries of different kinds of marble; the adjacent rocks are romantic; the air is healthy, and the inhabitants long-lived. Here is a conſiderable manufacture of woollen cloth; and in its environs ſome excellent cheeſe is made. The town is ſaid to contain 1484, and the canton 12,759 inhabitants, on a territory of 152½ kiliometres, in 12 communes; 20 miles E.S.E. of Liege. N. lat. 50° 36′. E. long. 23° 30′.

LIMBRA, a town of Hindooſtan, in Guzerat; 35 miles W. of Gogo.

LIMBRY, a town of Hindooſtan, in Guzerat; 68 miles W. of Amedabad.

LIMBURG, a lordſhip and principality of Germany, belonging to the circle of Franconia, but ſituated in Swabia; extending from S. to N. almoſt 20 miles, and from W. to E. 18 miles.—Alſo, a town of Germany, ſeated on the Lahn; 26 miles N. of Mentz. N. lat. 50° 20′. E. long. 8° 3′.—Alſo, a town and citadel of Germany, called *Hohen-Limburg*, which gives name to a county, a fief of the county of Mark, in which it is inſulated; about 15 miles long and 12 broad; 30 miles E. of Duſſeldorp.

LIMBUS, or LIMB, is a term in the *Roman Theology*, uſed for that place where the patriarchs are ſuppoſed to have waited for the redemption of mankind, and where they imagine our Saviour continued from the time of his death to that of his reſurrection.

Du-Cange ſays, the fathers call this place *limbus, eo quod ſit limbus inferiorum*, as being the margin or frontier of the other world.

LIMBUS is alſo uſed by Catholics for the place deſtined to receive the ſouls of infants, who die without baptiſm; who have not deſerved hell, as dying in innocence; nor yet are worthy of heaven, becauſe of the imputation of original ſin.

LIMBUS *Corollæ*, in *Botany*, the expanded part, or border, of a monopetalous corolla, ſupported by the tube, and analogous to the *lamina* of each petal in a polypetalous one. See COROLLA and LAMINA.

LIMBUYAN, in *Geography*, a town on the S. coaſt of the iſland of Maſbate. N. lat. 12° 8′. E. long. 123° 36′.

LIME, LIME-STONE, in *Mineralogy*, *Kalkſtein*, Germ. *Pierre calcaire, Chaux carbonatée*, Fr. This ſpecies of the carbonates of lime is divided by Werner into four ſubſpecies. 1. Compact lime-ſtone. 2. Foliated lime-ſtone. 3. Fibrous lime-ſtone. 4. Pea-ſtone.

1. *Compact lime-ſtone*, is ſubdivided into common compact lime-ſtone, and roe-ſtone.

A. *Common compact lime-ſtone; Gemeiner dichter kalkſtein*, Wern. *Pierre calcaire compacte commune*, Broch. *Chaux carbonatée compacte ou groſſière*, Haüy. *Compact lime-ſtone*, Kirwan. *Tätt kalkſten*, Swed.

Among the numerous colours of common compact lime-ſtone, the moſt frequent are the various ſhades of grey, ſuch as ſmoke-grey, yellowiſh-grey, bluiſh-grey, reddiſh and greeniſh-grey; it is alſo ſeen greyiſh-white, greyiſh-black, fleſh-red, with ſome deep tints of red and of yellow; ſeveral of theſe colours often occur in the ſame fragment, and moſtly in ſuch veined, clouded and other delineations which are diſtinguiſhed by the epithet of *marbled*.

It is moſtly found maſſive, ſometimes in rolled, ſeldom in tabular pieces, frequently with, and almoſt entirely compoſed of, extraneous foſſils, particularly ſhells.

Internally it is dull. Its texture is always more or leſs cloſely compact, ſometimes wax-like; fracture ſmall and fine ſplintery paſſing into large and flat conchoidal, and ſometimes into even. Fragments indeterminately angular, more or leſs ſharp-edged.

The varieties having a cloſe texture are tranſlucent on the edges.

It is ſemi-hard, ſometimes approaching to ſoft; brittle; eaſily frangible.

Specific gravity from 2.500 to 2.700.

It is chiefly compoſed of lime, carbonic acid, and water; but is ſeldom without an admixture of ſome argil and oxyd of iron, and ſometimes inflammable matter.

This widely extended ſubſtance occurs principally as fletz rock, but it is alſo found in the tranſition mountains.

The tranſition lime-ſtone is generally more tranſlucent on the edges, and very often exhibits variegated colours, particularly black, ſmoke-grey, bluiſh and greeniſh-grey, and red. It contains, like the fletz lime-ſtone, petrifactions, but moſtly of ſea animals, the prototypes of which do no longer exiſt. With regard to the petrifaction, both in the tranſition and fletz lime-ſtone, it is to be obſerved, that they occur pretty regularly diſpoſed; different ſtrata being generally furniſhed each with particular genera or even ſpecies.

Fletz lime-ſtone occurs, almoſt without exception, diſtinctly ſtratified; the ſtrata are ſometimes very thin, of which we have a remarkable inſtance in the lime-ſtone quarries of Sollenhofen, near Pappenheim, in Germany. Theſe ſtrata, which, as Mohs informs us, are very regular and perfectly horizontal, contain the well-known petrifactions which are called after that place, but are much leſs frequently found than is generally imagined.

M. de Bournon ſays, that in the Alps of Dauphiné lime-ſtone is found in ſtrata of no more than one or two inches in thickneſs, in which caſe it is not unfrequently mixed with quartz. This lime-ſtone in tables, called *lauſes* in Dauphiné, is employed for encloſing fields: a ſimilar variety is found at Grenoble at the foot of the mountains of Saſſenages.

Fletz lime-ſtone is frequently alternating with ſubordinate ſtrata of marle, and bituminous marle ſlate; but in theſe caſes the lime-ſtone is generally greatly predominating. The exterior of mountains compoſed of fletz lime-ſtone is of a peculiar kind; the hills formed by it are ſeldom conical, but blunt and maſſy, and interſected by deep vallies.

There are, beſides the tranſition lime-ſtone, ſeveral other formations of compact lime-ſtone. That called by Werner the *firſt fletz lime-ſtone* is the oldeſt; its loweſt ſtratum is the bituminous and cupriferous marle ſlate, or the *kupfer-ſchiefer-fletz*, as it is called by German miners: it extends round a great part of the oldeſt mountains of Germany, ſuch as the Hartz, the Thuringian foreſt, Suabia, &c. reſts on the old red ſand-ſtone, and is covered by the oldeſt fletz gypſum, or the variegated ſand-ſtone. It contains, beſides the above copper ſlate ſtrata, ſeveral ores of copper, cobalt, heavy ſpar, &c. being the productions of veins.

The ſecond formation of fletz lime-ſtone is called *ſhell-lime-ſtone*, on account of its abounding in petrifactions, which, however, are not peculiar to it, nor do they conſiſt in ſhells only, for the upper ſtrata contain likewiſe petrified crabs, vermiculites, ſpecies of aſterias, &c. (See SHELLS, *petrified*, and MARBLE.) It is widely extended, and appears moſt characteriſtic in Franconia, Suabia, and Bavaria. This formation is alſo remarkable, on account of the many caves which occur in it almoſt in all parts of the world, and many of them filled with the oſſeous remains of land animals. The moſt famous of theſe lime-ſtone caves are thoſe of Muggendorf and Galenreuth in Bayreuth, at Eichſtedt in Franconia, the Baumanſhole on the Hartz, thoſe of Dalmatia, Carniola, Hungary, Siberia, &c.

There are ſome other ſubordinate formations of fletz-lime-ſtone; which, however, require to be more cloſely examined before their characters can be determined with any thing like preciſion. Of ſuch apparently diſtinct depoſitions the following are mentioned by profeſſor Jameſon. 1. A fletz lime-ſtone, in Poland and Sileſia, which alternates with beds of lead-glance and calamine. It was formerly called the calamine formation, and Karſten conſiders it as ſubordinate to the firſt fletz lime-ſtone, but, according to Werner, it belongs to the ſecond. 2. A depoſit of lime-ſtone between Dreſden and Meiſſen, particularly near Plauen and in the vicinity of Göttingen, which was conſidered as a third fletz lime-ſtone formation, but is now claſſed as a mere variety of the ſecond fletz lime-ſtone: it is generally ſandy, or mixed with clay, and is therefore ſeldom uſed as lime, but principally employed as a building ſtone. It often contains petrifactions, ſuch as corallites, ammonites, &c. and ſometimes lead-glance is diſſeminated through it. 3. A lime-ſtone formation at Wehrau, in Upper Luſatia, containing newer petrifactions, ſuch as pectinites, mytilites, &c.: it alternates with beds of ſand-ſtone, and the whole reſts upon alluvial land. 4. A fletz lime-ſtone of a reddiſh-brown colour, frequently containing petrifactions; it is horizontally ſtratified, and contains beds of a variety of alum ſlate. Alſo a conchoidal lime-ſtone of Greece is mentioned as probably conſtituting a particular formation.

The uſes to which compact lime-ſtone is applied are various; it is principally employed as a building ſtone, and burnt for making lime and mortar; nor is it leſs important to the agriculturiſt as a manure, to the miner as a flux for the reduction of ores, to the ſoap-boiler, tanner, &c.

The fine-grained and variegated varieties of compact lime-ſtone, many of which are highly valued, are known by the name of *marble;* a term which is more particularly applied to the fine varieties of granular lime-ſtone, and alſo given to various mixtures of lime-ſtone with other ſubſtances. See MARBLE.

B. *Roe-ſtone; Roogenſtein,* Wern. *Oviform lime-ſtone,* Kirw. *Oolite,* Broch. *Chaux carbonatée globuliforme,* Haüy. *Meconite, pſammite,* &c.

Its colour is generally yellowiſh-brown, paſſing into various deeper ſhades of brown, ſuch as hair-brown, clove-brown; it is alſo found ſmoke-grey, yellowiſh, and reddiſh-grey. The colour of the globules is often different from that of the marley maſs by which they are cemented together.

It is found maſſive. It is dull. Fracture fine ſplintery, a character not eaſily obſervable, on account of the ſmallneſs of the diſtinct concretions. Fragments indeterminately angular, blunt-edged.

It conſiſts of ſpherical, granular, diſtinct concretions; each of which is generally compoſed of concentric lamellar concretions, which are either cemented together by a marley ſubſtance, or connected by ſimple contact; the grains vary in ſize, and are often ſo minute as to be ſcarcely diſtinguiſhable by the naked eye; the largeſt are nearly of the ſize of a pea, but theſe are ſeldom ſeen. In ſome varieties each globule is an aggregate of ſeveral ſmaller globules.

It is opaque, ſeldom tranſlucent on the edges.

It is ſoft and ſemi-hard; brittle; eaſily frangible. Specific gravity 2.456 — 2.494, Kirw.

Its chemical character is little different from that of the common compact lime-ſtone. The variety analyſed by Kirwan was compoſed of 90 parts of carbonate of lime and 10 of alumine, with ſome oxyd of iron.

This ſub-ſpecies is much leſs frequently met with than common compact lime ſtone. It occurs, however, in conſiderable quantities at Brunſwic, in Thuringia, particularly in the diſtrict of Weimar, in that of Mansfeld, Sangerſhauſen, Kloſterroda, &c. in Tyrol; in England, at Bath, in Derbyſhire, at Purbeck.

It occurs chiefly, in more or leſs conſiderable beds, in the variegated ſand-ſtone formation, to which it is ſubordinate, and between the ſtrata of which it is generally interpoſed with great regularity. It contains no petrifactions, nor is it metalliferous.

Roe-ſtone, being very ſubject to diſintegration, is ſeldom employed for the purpoſes of building; but it is in ſome countries uſed as a manure. The more compact varieties take a tolerably good poliſh.

The name of roe-ſtone is given to this mineral on account of its cloſe reſemblance to fiſh-roes; indeed, the old mineralogiſts were ſo far miſled by the imitative form of this ſubſtance, that they really conſidered it as the petrified roes of fiſh.

The origin of the ſtructure of roe-ſtone is not eaſily explained; ſome have conſidered it as a conglomerate of rolled pieces of lime-ſtone; others have aſſigned the ſame origin to it as to the pea-ſtone; but Werner conſiders it as the reſult of cryſtallization.

2. *Foliated lime-ſtone; Blättriger kalkſtein* of Werner, who divides this ſub-ſpecies into two kinds: 1. Granular lime-ſtone. 2. Calcareous ſpar.

A. *Granular lime-ſtone. Körniger kalkſtein,* Wern. *Foliated and granular lime-ſtone,* Kirw. *Pierre calcaire grénue,* Broch. *Chaux carbonatée ſaccaroïde,* Haüy. *Granular,* or *ſaline marble, ſtatuary marble,* &c.

Its chief colour is white, often ſnow-white, greyiſh, yellowiſh, and greeniſh and reddiſh-white; alſo bluiſh, greeniſh, aſh and ſmoke-grey, and greyiſh-black; from greeniſh-white it paſſes into yellowiſh and olive-green, and from reddiſh-white into pearl-grey and fleſh-red. Its colours are moſtly uniform, but it alſo occurs ſometimes ſpotted, and with ſtriped and veined delineations; and on their rifts the maſſes are now and then marked with dendritic figures.

It is maſſive. Internally it alternates from ſhining to gliſtening and glimmering; its luſtre being intermediate between pearly and vitreous.

Fracture foliated; ſometimes, on account of the ſmallneſs of the particles, it appears almoſt compact and ſplintery. Fragments indeterminately angular, not particularly ſharp-edged. It occurs almoſt always in granular diſtinct concretions, which are coarſe, ſmall, and fine-grained.

It is generally tranſlucid; the dark-coloured varieties tranſlucent only on the edges.

It is ſemi-hard, ſometimes hard when mixed with ſiliceous and argillaceous particles; brittle; eaſily frangible; ſeldom elaſtic.

Specific gravity 2.707 (white Carrara), Muſchenbr;—2.717 (the ſame), Kirwan;—2.837 (Parian), Briſſon;—2.849 (white Saxon), Gellert;—2.836, (elaſtic var. from Campo Longo), Fl. de Bellevue.

Pure white granular lime-ſtone is infuſible before the blow-pipe, and only crumbles to pieces. In the charcoal crucible, that of Carrara was found by Klaproth to be burnt to quicklime; while in the clay crucible it was fuſed into a compact, tranſparent, hard glaſs of a light glaſs-green colour. It uſually ſtrongly effervesces with nitric acid, and when pure is ſoon diſſolved in it without leaving a reſidue.

Granular lime-ſtone is almoſt always of primitive formation; it ſeldom occurs as tranſition rock, and ſcarcely ever as a production of ſecondary mountains, or if it be found in theſe, it is never in extenſive depoſitions, but only in beds of not very conſiderable dimenſions. As tranſition rock it principally occurs on the Hartz; it is found there of a grey colour, and of coarſe granular texture.

Primitive granular lime-ſtone is ſeldom ſeen very diſtinctly ſtratified; it moſt commonly occurs in conſiderable beds in gneiſs, mica ſlate, and clay ſlate, in which latter the tranſition lime-ſtone appears, which, however, principally belongs to compact lime-ſtone. It is generally ſimple, but alſo contains ingredients which are characteriſtic of it, ſuch as mica, quartz, ſerpentine, tremolite, hornblende, clay ſlate, garnets, magnetic iron-ſtone, blende, &c. Mixed with noble ſerpentine it conſtitutes the *verde antico*.

The common varieties are employed for the ſame purpoſes as compact lime-ſtone; the finer are among the moſt ſplendid and deſirable materials for ſtatuary and architecture, and for the decoration of the interior of houſes. See MARBLE, under which article alſo ſeveral of the numerous localities of this ſub-ſpecies will be given.

Some varieties of granular lime-ſtone have manifeſted a conſiderable degree of flexibility; one of theſe was diſcovered by M. Fleuriau de Bellevue, at an elevation of 6000 feet, on Campo Longo, on mount Gothard. The ſame phenomenon may be artificially produced by expoſing granular lime-ſtone to a certain degree of heat.

2. *Calcareous ſpar.* *Calc ſpar*, Jam. *Kalkſpath*, Wern. *Common ſpar*, Kirw. *Spath calcaire*, Broch.

Its principal colour is white, which is pure and ſnow-white, or greyiſh, yellowiſh, greeniſh, and ſeldom reddiſh; it occurs alſo olive, aſparagus, piſtachio and leek-green; greeniſh-grey, yellowiſh-grey, honey, ochre, wine, and wax-yellow; fleſh-red, brown-red, and very rarely roſe-red; ſmoke-grey paſſing into black; very ſeldom pearl-grey, and light violet-blue.

It occurs maſſive and diſſeminated, alſo druſed and ſtalactitical, but moſt commonly cryſtallized.

The primitive figure of the cryſtals is an obtuſe rhomboid of 101° 32′ 13″, and 78° 27′ 47″, according to Haüy; and of 101° 32′, and 78° 28′, according to Bournon.

The integrant molecule, as obſerved by Monſ. de Bournon, is a trihedral priſm with inclined baſes. The number of modifications derived from the primitive rhomboid is very conſiderable; thoſe enumerated in the laſt mentioned author's very elaborate "Traité de Minéralogie," amounting to no leſs than fifty-nine.

The figures ſuppoſed fundamental by Werner, and from which all the others may be derived, are: the ſix-ſided pyramid, the ſix-ſided priſm, and the three-ſided priſm. The following Wernerian deſcription of the different varieties of calcareous ſpar is from Jameſon's Mineralogy.

1. *The ſix-ſided Priſm.*—When perfect it is acute, and three alternate lateral edges are more obtuſe than the others. It occurs 1. *Simple;* either erect or inverted. The inverted has three cylindrical concave, and three inwardly bent lateral planes, and on the upper extremity it is flatly acuminated by three planes, which are ſet on the cylindrically concave lateral planes. 2. *Double*, where the lateral planes of the one are obliquely ſet on the lateral planes of the other, in ſuch a manner, that the edges of the common baſis form a zigzag line, and the more obtuſe lateral edges of the one are oppoſed to the leſs obtuſe lateral edges of the other pyramid. Of this figure the following varieties occur: *a.* The extremity of the pyramid is ſometimes more or leſs deeply and flatly acuminated by three ſomewhat convex planes, which are ſet on the more obtuſe lateral edges? *b.* The angles of the common baſe are often more or leſs deeply truncated; when the truncating planes become ſo large that they touch one another, the tranſition into the ſix-ſided priſm is formed. *c.* The leſs obtuſe edges are ſometimes bevelled, and the extremities ſometimes more or leſs deeply truncated. *d.* If two double ſix-ſided pyramids penetrate one another in the direction of their axis, and one of them is turned around a ſixth of its periphery, ſo that the leſs obtuſe lateral edges of the one cryſtal come to be oppoſed to the leſs obtuſe lateral edges of the other, the reſult is a twin cryſtal, repreſenting a double ſix-ſided pyramid having three alternate re-entering angles at the common baſe, where the more obtuſe lateral edges are oppoſed to one another.

2. *Six-ſided Priſm.*—It occurs uſually with three alternate lateral planes broader than the others, and rather acutely acuminated by ſix planes which are ſet on the lateral edges, and the acuminating planes meet alternately under more obtuſe angles. *a.* The ſame priſm a ſecond time flatly acuminated by three planes, which are ſet on the alternate obtuſe lateral edges of the firſt acumination. *b.* When the planes of the ſecond acumination enlarge ſo much that thoſe of the firſt entirely diſappear, there reſults the ſix-ſided priſm flatly acuminated by three planes, which are ſet on the alternate and alternating lateral planes. *c.* The apex of the acumination is often more or leſs deeply truncated, which produces the ſix-ſided priſm, in which the alternate and alternating terminal angles are truncated. *d.* When the truncation of the apex becomes ſo large that all traces of the acumination diſappear, the perfect ſix-ſided priſm is formed. *e.* When the priſm becomes lower, it paſſes into the ſix-ſided table, which is often extremely thin.

3. *Three-ſided Pyramid.*—1. Simple three-ſided pyramid, whoſe ſummit angle is of various degrees of magnitude, from obtuſe to acute. 2. If the angles of the preceding figure are ſo deeply truncated, that the angles of the truncating planes meet each other, an octahedron is formed. 3. The pyramid is often double; in which caſe, the lateral planes of the one pyramid are ſet on the lateral edges of the other. It preſents the following varieties: *a.* Flat double ſix-ſided pyramid, which has ſometimes convex lateral planes. *b.* If a number of theſe flat or obtuſe pyramids are piled on one another, there is formed a ſix-ſided priſm acuminated by three planes, which are ſet on the alternate and alternating lateral planes. *c.* When this pyramid becomes very obtuſe, it gives riſe to the lens. *d.* When the ſummits of the pyramid become leſs obtuſe, and approach to right angles, a figure differing but little from the cube is formed. *e.* When

the ſummits become ſtill more acute, an acute double three-ſided pyramid is formed. *f.* The acute double three-ſided pyramid is ſometimes truncated on the lateral edges, ſometimes bevelled: in the latter caſe, when the bevelling planes become ſo large that the original ones are very ſmall, or even diſappear, the reſult is an acute double three-ſided pyramid, having its planes length-wiſe divided; or it is a double ſix-ſided pyramid. *g.* If the ſummits of the double ſix-ſided pyramid are deeply truncated, it gives riſe to the ſix-ſided table, having its terminal planes ſet on alternately in oppoſite directions.

Though the preceding deſcription of the different modifications of calcareous ſpar may poſſeſs the merit of ſpeaking to the eye, yet it can by no means ſuperſede the details of a ſtrictly cryſtallographical inveſtigation; we therefore ſubjoin a ſhort abſtract of the excellent claſſification given by count Bournon, in the firſt volume of his "Traité de Minéralogie" lately publiſhed.

All the modifications of cryſtallized carbonate of lime are by this author divided into, 1, priſmatic; 2, rhomboidal; and 3, pyramidal modifications.

I. *Priſmatic Modifications.*

1. *Priſm from the edges of the baſe of the primitive cryſtal;* or theſe edges intercepted each by a plane.—Of this, a variety with very ſhort priſm occurs in Cumberland and Derbyſhire. That with long priſm (Chaux carbon. *priſmé*, Haüy, pl. 24. f. 10) is likewiſe found in Cumberland. The variety in which the lateral planes form rhombs, ſo that the cryſtal at firſt ſight has the appearance of the garnet dodecahedron, is the ſcarceſt of this modification.

2. *Priſm from the ſolid angles of the baſe;* theſe angles of the primitive cryſtal being intercepted each by a plane.—The chaux carb. *imitable*, Haüy, (ib. fig. 12.) belongs to this modification. It is generally ſeen in combination with others. Sometimes two of the planes of the pyramid of the primitive rhomboid enlarge at the expence of the third; and ſometimes one of them cauſes, in the ſame manner, the two others to diſappear. Found in Cumberland, Dauphiné, and on the Hartz.

3. *Summit intercepted by a plane perpendicular to the axis.*—This modification ſeldom occurs in its ſimple ſtate. The varieties in which this plane is of conſiderable extent is called chaux carb. *baſée* by Haüy (pl. 23. fig. 8.) This is frequently ſeen united with the preceding modifications; in which caſe, if the new plane has cauſed the pyramid of the rhomboid entirely to diſappear, the chaux carb. *priſmatique*, Haüy, (pl. 24. fig. 14.) is produced, the fineſt groups of which are found in Cumberland and on the Hartz. Some of the lateral planes of theſe priſms frequently enlarge, at the expence of the adjoining planes; ſo that one, two, or even three, entirely diſappear. The cryſtals of the regular hexahedral priſmatic variety, from the Hartz, are not unfrequently ſeen with white opaque ſurface, and alſo ſometimes to include ſimilar cryſtals of ſmaller diameter, which now and then project above the terminal plane of the larger cryſtal. The priſm of this variety is often ſo ſhort as to repreſent a thin ſix-ſided table. When both the ſecond and the firſt modifications are united in the priſm, we have the chaux carb. *péridodécaèdre* of Haüy (pl. 26. fig. 33.)

II. *Rhomboidal Modifications.*

A. *Obtuſe Rhomboids.* Of theſe, Nos. 5, 6. 8, and 9, have not before been noticed.

4. *Obtuſe rhomboid of* 114° 19', *and* 65° 41'.—One of the moſt common modifications, and more frequently than all the reſt (except the preceding) combined with other modifications. It is produced by the edges of the pyramids of the primitive rhomboid being replaced each by a plane equally inclining on thoſe by which the edge itſelf is formed. In its complete ſtate, this modification is the chaux carb. *équiaxe* of Haüy (pl. 23. fig. 2.), which is much more frequently met with than the different paſſages of the primitive rhomboid into this modification. The planes of this fourth modification are often longitudinally ſtriated; and when they are arrived at their limits, the ſtriæ run parallel to the ſhorter diagonal of the rhomboidal planes.—This is found united principally with No. 2, repreſenting various degrees of elongation of the chaux carb. *dodécaèdre*, Haüy (pl. 24. fig. 18.): found alſo as twin cryſtals in Derbyſhire; with No. 1, belonging to the chaux carb. *biſunitaire*, Haüy (fig. 17.), chiefly from Cumberland (rare); with Nos. 1 and 2, and with Nos. 2 and 3, chaux carb. *équivalente*, Haüy (pl. 25. fig. 28.), both from Cumberland; with Nos. 2 and 3, and part of the primitive planes, whence it is called chaux carb. *triforme* by Haüy (fig. 26.). The laſt mentioned variety is from the Hartz; and both the ſpecimen of Haüy and that deſcribed by M. de Bournon are remarkable, for having part of the pyramid covered with cryſtalline matter, which appears to be depoſited after the cryſtal had been completed, and is thus forming a paſſage into the regular hexahedral priſm.

5. *Very obtuſe rhomboid of* 117° 56', *and* 62° 4'.—It is produced by the edges of the primitive rhomboid being replaced each by a plane, which is inclined towards its ſummit. This has hitherto been found only in combination with other modifications, *viz.* Nos. 2 and 3. The cryſtals are all from the Hartz, where red ſilver ore is ſometimes accompanied with them. The variety of calcareous ſpar, called *en roſe*, generally belongs to the complete rhomboid of this modification, as alſo moſt of thoſe known by the names of coxcomb and lenticular ſpar; but they are ſeldom determinable by the goniometer.

6. *Obtuſe rhomboid of* 113° *and* 67°.—This is eaſily confounded with the preceding modification. Count Bournon has obſerved it only in a few inſtances, combined with the planes of Nos. 1, 2, and 36 (*vide infra*), in cryſtals from Derbyſhire and Cumberland.

7. *Obtuſe rhomboid of* 107° 3', *and* 72° 57'.—This is the reſult of a decrement of the laminæ, ſimilar to that which produces the preceding modification; but the planes thus formed are more inclined on the baſe of the primitive rhomboid. To this is to be referred Haüy's chaux carb. *quadrirhomboïdale.* (Ann. du Muſ. d'H. Nat. t. 1. pl. 8. fig. 4.) It is always obſerved in combination with other modifications, ſuch as with thoſe of Nos. 1, 2, and with thoſe of the primitive cryſtal. They come from Dauphiné and Derbyſhire. This modification has not yet been ſeen perfect; though nearly ſo, in a variety which has very narrow planes of No. 1. One variety from Derbyſhire, which has the priſm of No. 2 combined with this modification, and part of the planes of the primitive rhomboid, might be eaſily miſtaken for priſmatic rock cryſtal, of which it has ſometimes the tranſparency. The planes marked *l* in Haüy's chaux carb. *rétrograde*, (pl. 26. fig. 36.) belong to this variety.

8. *Very obtuſe rhomboid of* 118° 34', *and* 61° 26'.—This moſt obtuſe of all rhomboids known to occur in calcareous ſpar, is the reſult of a decrement of the cryſtalline laminæ, at the obtuſe angles of the planes that form the ſolid angle of the ſummit, which is thus replaced by three planes reſting on thoſe of the primitive rhomboid. This modification, which is ſcarce, does not occur in its complete ſtate: beſides with planes of the primitive rhomboid, it has been obſerved

in combination with thoſe of Nos. 1, 3, 5, 8, 41, and 43; moſt of them from the Hartz. Perhaps ſome of the very flat lenticular varieties of calcareous ſpar may be alſo referable to this modification.

9. *Slightly obtuſe rhomboid of* 95° 28′, *and* 84° 32′.—This very rare modification is produced by the obtuſe angles on the baſe of the primitive rhomboid being replaced, each by a plane reſting on the correſponding primitive planes. It is obvious, that the cleavage of this rhomboid muſt be different from that of the laſt mentioned modification, by being on the planes of the ſummit inſtead of the baſe; while that of all the preceding rhomboids, likewiſe at the baſe, takes place on the edges. This rhomboid has been obſerved perfect in ſpecimens from Siberia; and in combination with the planes of No. 36.

B. *Acute rhomboids.* Nos. 10, 12, 15, 16 and 18—21 of this diviſion are new.

10. *Acute rhomboid of* 65° 28′, *and* 114° 32′.—The obtuſe angles of the primitive rhomboid replaced each by a plane, as in the preceding; but being the reſult of a more rapid decrement of the laminæ, its axis is three times longer than that of the primitive rhomboid. Occurs, though rarely, in Derbyſhire, both in its complete ſtate, and in combination with remains of the planes of No. 2.

11. *Acute rhomboid of* 45° 34′, *and* 134° 26′.—The reſult of a decrement on the ſame angles as in the preceding, but the decrement producing a rhomboid much more acute. It is the chaux carb. *contraſtante* of Haüy (pl. 23. fig. 5.) one of the moſt common rhomboids that occur in calcareous ſpar. It occurs perfect, ſometimes with traces of the primitive planes, and in combination with Nos. 1, 2, 3, 4, and 36. Is found in Derbyſhire, Cumberland, at Grenoble in France, on the Hartz, &c. When the planes of the rhomboid of this modification are combined with thoſe of the common acute pyramidial dodecahedron, No. 36, they replace the ſolid angles of the baſe of this dodecahedron in the form of an elongated trapezoid.

12. *Acute rhomboid of* 40° 26′, *and* 139° 34′.—Decrement on the ſame angles as in the preceding, to which it approaches cloſely. Occurs moſtly in its complete ſtate in Derbyſhire, and has been ſeen combined in the ſame cryſtal with planes of the primitive rhomboid, and Nos. 1, 14, and 36, in which latter its planes are placed nearly in the ſame manner as thoſe of the rhomboid of the preceding modification.

13. *Very acute rhomboid of* 15° *and* 165°.—Decrement on the ſame angles as in the preceding modifications, but giving origin to a much more acute rhomboid. Count Bournon has obſerved it in its complete ſtate. It is ſeldom ſeen, and it is difficult to preſerve it, on account of the great fragility of the fine termination of the cryſtals. Combinations of the planes of this and No. 4 occur in Derbyſhire, on the Hartz, &c. and in Cumberland, generally on cryſtals of ſulphate of barytes; the one called chaux carb. *contractée* (Haüy, pl. 24. fig. 20.) belongs to it. Fine groups of this modification in its complete ſtate have been found in Weſtmoreland; and in the ſame ſpecimen, combined with planes of the very acute pyramidal dodecahedron, No. 54.

14 *Slightly acute rhomboid of* 87° 42′, *and* 92° 18′.—This is the chaux carb. *cuboïde* of Hauy, (pl. 23. fig. 7.) It occurs complete, with planes of the primitive rhomboid, and combined with the planes of ſeveral other modifications, ſuch as Nos. 1—4, and No. 15, in Languedoc, at Strontian, Bath, in Derbyſhire, and on the Hartz. This modification, combined with the planes of No. 3, is the chaux carb. *apophane* of Haüy, (pl. 24. fig. 15.)

15. *Acute rhomboid of* 84° 26′, *and* 95° 34′.—This rhomboid, the preceding, and all the following, are the reſult of a decrement of the cryſtalline laminæ on the obtuſe angles of the baſe; and the cleavage in all of them takes place at the ſummit, and on the edges of the cryſtal. Though combined with moſt of the other modifications, the planes of this rhomboid have never been mentioned by cryſtallographers, a circumſtance probably owing to their ſmallneſs, and their having been confounded with the preceding, from which it is, however, eaſily diſtinguiſhed, even without the aſſiſtance of the goniometer. It is ſometimes found in a complete ſtate on the Hartz, and at Strontian in groups, accompanied with ſtilbite and croſs-ſtone, or harmotome; and in combination with the planes of Nos. 1—5. and alſo with the remains of thoſe of the primitive rhomboid.

16. *Acute rhomboid of* 81° 19′, *and* 98° 41′.—This is oftener ſeen in its complete ſtate than combined with the planes of other modifications, ſuch as thoſe of Nos. 1, 2, 3, 4, and 36; it alſo occurs with traces of the primitive rhomboid. Moſt of theſe were brought from the iſland of Ferroe, and from Scotland; the former moſtly in groups, with ſtilbite zeolite, the others with analcime zeolite. The variety in which it is combined with No. 4, came from Caſtagna-moro, in Italy. Their gangue, in the above places, is a wacke like rock.

17. *Acute rhomboid of* 75° 31′, *and* 104° 29′.—This is the chaux carb. *inverſe* (Haüy, pl. 23. fig. 3.), ſo called becauſe this rhomboid is, as it were, an inverſion of the primitive. Next to No. 14, it is the moſt common of all the modifications of calcareous ſpar; but a circumſtance worth remarking is, that it ſcarcely ever occurs in any other but ſhell lime-ſtone; while the reverſe prevails with regard to the primitive rhomboid which, in its perfect ſtate, is ſeldom found in any but the older formations of lime-ſtone. The name of *muriatique*, given to this rhomboid by Romé de l'Iſle, is derived from the juſt mentioned mode of occuring. The complete rhomboid frequently occurs in veins at Bath, in Derbyſhire, and lining hollows of ſhell-marble in ſeveral other parts of Britain. In ſtill greater perfection it is found, together with various combinations of the planes of other modifications, in the ſhell lime-ſtone of Couſon, near Lyons, and in thoſe of Vougy, near Roanne, in Forez; in the former of theſe places it is generally ſeen in the interior of ſiliceo-calcareous geodes; in the latter in geodes of black, earthy, and compact black manganeſe, with mammillary internal ſurface. It has been obſerved by M. de Bournon combined with the planes of the primitive rhomboid, and with thoſe of Nos. 1 to 4, and Nos. 11, 14, 36, 37, and 49. That with narrow remains of the primitive planes is Haüy's chaux carb. *unitaire* (pl. 23. fig. 9.); that with remains of the primitive planes, and thoſe of the priſm No. 2, has been deſcribed by the ſame cryſtallographer under the name of chaux carb. *unibinaire* (Ann. du Muſ. Par. vol. i.); that with the planes of the ſame priſm No. 2, and with thoſe of No. 3, is Haüy's chaux carb. *perſiſtante* (pl. 25. fig. 29.); the ſame with additional remains of the planes of No. 4, is his chaux carb. *coordonnée*; and a variety in which this rhomboid is combined with narrow planes of Nos. 1, 2, 3, 4, and 37, is deſcribed by him under the name of chaux carb. *quadruplante*. (Ann. du Muſ. vol. i.)

18. *Acute rhomboid of* 70° 18′, *and* 109° 42′.—This rhomboid is very rare, and has been ſeen in combination only with the planes of the priſm No. 2, accompanied by planes of Nos. 23, 30, 36, and of the primitive rhomboid. Theſe cryſtals occur in Cumberland and in Derbyſhire.

19. *Acute rhomboid of* 61 12′, *and* 118 48′. This has been obſerved by count Bournon, in its complete ſtate, in a

maſs of brown iron-ſtone; and alſo in combination with the planes of the primitive rhomboid and thoſe of Nos. 1, 2, 3, 4, 11, and 36. The cryſtals exhibiting this modification are, with a few exceptions, all from Derbyſhire.

20. *Acute rhomboid of* 55° 34', *and* 124° 26'.—This rhomboid, which has been obſerved complete, and in combination remains of the primitive planes, and thoſe of Nos. 2 and 3, is of ſtill rarer occurrence than the preceding. Found in Derbyſhire and Cumberland. The preceding, and the next modification, ſometimes exhibit, underneath their pyramidal edges, the planes of the primitive rhomboid, which, eſpecially when of a different tint from the reſt, are viſible through the ſubſtance of the cryſtal; a phenomenon produced by a ſuperpoſition of cryſtalline matter on the cryſtal already formed.

21. *Acute rhomboid of* 50° 54', *and* 129° 6'.—This occurs both ſimple and combined with other modifications, ſuch as Nos. 1, 2, 3, 4, 11, 17, and 46, in the Hartz, in Cumberland, and more frequently in Derbyſhire. It is often ſeen to accompany ſtalactitical varieties of calcareous ſpar.

22. *Very acute rhomboid of* 37° 31', *and* 142° 29'—This is the chaux carb. *mixte* of Haüy (pl. 23. fig. 6.) It is, like the preceding, not unfrequently met with, particularly as accompanying ſtalactitical lime-ſtone; it occurs as often in a complete ſtate as combined with the planes of other modifications, among which are Nos. 2, 3, 4, 7, 11, 14, and 46. They are principally found in Derbyſhire. The variety which is combined with the planes of No 4, has been deſcribed by Haüy under the name of *unimixte* (Ann. du Muſ. vol. i.); and that with the planes of No 11, and remains of the primitive planes, is called by the ſame cryſtallographer chaux carb. *tri-rhomboidale* (Min. pl. 25. fig. 17.); that with additional traces of the planes of No. 7, is his chaux carb. *quadri-rhomboidale* (Ann. du Muſ. vol. i.). When the planes of this variety, and thoſe of Nos. 11 and 3, are united at the extremities of the priſmatic modification No. 2, it is Haüy's chaux carb. *annulaire* (ibid.)

23. *Extremely acute rhomboid of* 14° 6', *and* 165° 54'.—This is the moſt acute of all the rhomboids that belong to calcareous ſpar. It is ſeldom ſeen in its complete ſtate, both on account of its minuteneſs and its extreme fragility; M. de Bournon has, however, obſerved it ſeveral times on the groups of calcareous ſpar from the Hartz, which are conſidered as filiform and indeterminable. The combination of the planes of this with thoſe of No. 4, is named chaux carb. *dilatée* by Haüy (pl. 24. fig. 21.), which occurs alſo as macle; that with traces of the planes of Nos. 3 and 17 is the ſame cryſtallographer's chaux carb. *hyperoxide* (pl. 25. fig. 30.); and that with Nos. 4 and 7, his chaux carb. *rétrograde* (pl. 26. fig. 36.) It occurs alſo with the planes of ſeveral other modifications. This rhomboid might eaſily be miſtaken for that of No. 13, which is, however, the reſult of quite a different decrement of the cryſtalline laminæ, and conſequently has a different cleavage.

III. *Pyramidal Modifications.*

The ſeveral pyramidal dodecahedrous belonging to this diviſion, are here diſtinguiſhed from each other by the meaſure of the ſolid angle of their ſummit, taken on two oppoſite edges of the pyramid.

A. *Pyramidal obtuſe dodecahedrons.*—The modifications of this ſub-diviſion of pyramidal dodecahedrons are, upon the whole, very rare, and almoſt peculiar to England, where they occur in Derbyſhire, Cumberland, and Durham. When the planes of ſeveral of thoſe modifications are combined in the ſame cryſtal, their narrowneſs, together with the very obtuſe angles they form with one another, ſometimes produces curvilinear planes, eſpecially when they are, at the ſame time, combined with the planes of ſeveral of the rhomboidal modifications.

The following ten modifications, with the exception of Nos. 27 and 30, have not been noticed before.

24 *Obtuſe pyramidal dodecahedron of* 134° 28'.—This modification (as well as thoſe that follow), is the reſult of a retrogradation of the cryſtalline laminæ, along, and parallel with, the edges of the pyramids of the primitive rhomboid, replacing each of theſe edges by a double plane or bevelment. Three of the edges in each pyramid of this modification muſt, therefore, be exactly in the ſame direction with thoſe of the primitive rhomboid. It has not been obſerved either in its paſſage from the primitive rhomboid, or as complete dodecahedron, but only in combination with very ſhort planes of the priſm No. 2 (from Cumberland); with thoſe of Nos. 2, 4, and 36, in a pyramidal cryſtal from Derbyſhire; and with thoſe of Nos. 2 and 35, from the ſame county.

25. *Obtuſe pyramidal dodecahedron of* 126° 51'.—This modification, if it exiſted in a complete ſtate, would exhibit pyramids with planes forming iſoſceles triangles, and conſequently with all the angles of the common baſe on the ſame level. M. de Bournon has but twice obſerved this modification; and in both caſes combined with the planes of ſeveral other modifications, among which thoſe of the priſm No. 2 are the moſt apparent. From Derbyſhire.

26. *Obtuſe pyramidal dodecahedron of* 124° 36'.—This is of much more frequent occurrence than the preceding, from which it differs eſſentially, in having ſcalene triangles. The complete dodecahedron comes from Derbyſhire; a combination of its planes with thoſe of No. 2 from Cumberland. In Derbyſhire it is alſo found combined with the planes of ſeveral other modifications, of which thoſe of Nos. 2 and 36 are the moſt characteriſtic.

27. *Obtuſe pyramidal dodecahedron of* 121° 26'.—The planes that terminate Haüy's chaux carb. *ſonſtractive* (pl. 26. fig. 37.) belong to this modification. They are alſo ſeen in his chaux carb. *ſurcompoſée* (pl. 28. fig. 50.), in which five modifications are combined. Cryſtals with planes of this dodecahedron are common in Derbyſhire and Cumberland, where it occurs combined with the planes of ſeveral other modifications. The complete dodecahedron is ſcarce.

28. *Obtuſe pyramidal dodecahedron of* 118° 26'.—Has not yet been found in a complete ſtate. The ſimpleſt combination is that with the very ſhort planes of the priſmatic modification No. 2. But it generally occurs together with the planes of ſeveral other modifications, ſuch as with Nos. 4, 7, 11, 27, 28, and 36, and in ſome of theſe alſo, with remains of the planes of the primitive rhomboid. Found principally in Derbyſhire and Cumberland.

29. *Obtuſe pyramidal dodecahedron of* 117° 25'.—Differs but little from the preceding. It has not been found in a complete ſtate, nor are its planes often ſeen combined with thoſe of other modifications; among thoſe figured by M. de Bournon are Nos. 2, 15, 17, and 36. The cryſtals which exhibit its planes are moſtly from Derbyſhire.

30. *Obtuſe pyramidal dodecahedron of* 115° 17'.—Its planes are repreſented in Haüy's chaux carb. *disjointe* (pl. 26, fig. 38.), in which it is combined with thoſe of Nos. 2 and 36. In the ſame author's chaux carb. *binoſenaire* (Ann. du Muſ. vol. i.) it is ſeen without the planes of the priſmatic modif. No. 2, but with thoſe of No. 36; and his chaux carb. *additive* (ibid.) is the biſonaire, augmented by the planes of No. 4. Theſe cryſtals are ſaid to come from Derbyſhire. M. de Bournon has not himſelf ſeen cryſtals with planes of this modification.

31. *Obtuſe, pyramidal dodecahedron of* 100° 24′.—The planes produced by the retrogradation of the cryſtalline laminæ replace the edges of the primitive rhomboid, but inſtead of being parallel to them, as in the preceding modifications, they become narrower towards the ſummit of the rhomboid. The two pyramids of this dodecahedron are, like thoſe of No. 25, compoſed of iſoſceles triangles, whence the angles of their baſe muſt be upon a level. It has not yet been obſerved in its complete ſtate; but in a variety compoſed of its planes and thoſe of Nos. 35 and 2, M. de Bournon has ſeen it terminate the cryſtal in a very regular manner. It has alſo been obſerved in a cryſtal in which the planes of No. 2, and in another in which thoſe of No. 36. are predominant. The cryſtals exhibiting the planes of this modification are rare, and have been found only in Derbyſhire and Cumberland.

32. *Obtuſe pyramidal dodecahedron of* 101° 6′.—This has not been ſeen complete, but in combination with the planes of ſeveral other modifications producing very complicated cryſtals. They occur in Derbyſhire, but rarely. The cleavage of this dodecahedron takes place at the baſe on the leſs obtuſe edges.

33. *Obtuſe pyramidal dodecahedron of* 95°.—The cryſtals in which are ſeen the planes of this modification occur but ſeldom, and are ſtill more complicated than thoſe with the planes of the preceding modification. One of the two cryſtals figured by M. de Bournon comprehends 72, and the other no leſs than 84 planes, of which thoſe of the priſmatic modification, No. 2, are the principal ones. They were found in Derbyſhire. The cleavage of this dodecahedron is the ſame as that of the preceding modification.

B. *Acute pyramidal dodecahedrons.*—The following modifications, with the exception of Nos. 34, 36, 39. 48* and 50, are all new.

34. *Acute pyramidal dodecahedron of* 88° 53′.—The planes of this dodecahedron are the reſult of a decrement of the cryſtalline laminæ along the edges of the baſe of the primitive rhomboid: cleavage at the ſummit on the more obtuſe edges. Theſe planes are marked *v* in Haüy' figure of his chaux carb. *bigéminée* (pl. 27. fig. 49.) Beſides in this combination, (in which the planes of No. 36. are the moſt prominent,) M. de Bournon has obſerved them with the planes of Nos. 2, 29, and 34, in two cryſtals from Cumberland, where alſo the complete dodecahedron has been found. The planes of this modification are of rare occurrence.

35. *Acute dodecahedral pyramid of* 78° 40′.—This is far leſs ſcarce than the preceding modification, with which it agrees in the nature of the decrement and the cleavage. Has not yet been obſerved in its complete ſtate. Its planes are repreſented in Haüy's figure of chaux carb. *aſcendante* (pl. 27. fig. 44. *n*), in which they are combined with thoſe of Nos. 2 and 11. Another cryſtal has been deſcribed by Haüy, under the name of *ſouſquadruple* (Ann. du Muſ. vol. ii.), which differs from the latter in having alſo traces of No. 28. The dodecahedron has not been ſeen in its complete ſtate, but our author poſſeſſes cryſtals in which the two pyramids are ſeparated from one another only by ſhort planes of the priſmatic modification No. 2. Beſides this, its planes have been obſerved in combination with ſome other modifications. Theſe cryſtals have been found in Derbyſhire.

36. *Acute pyramidal dodecahedron of* 48° 22′.—This is Haüy's chaux carb. *métaſtatique* (pl. 40, fig. 70), a modification which, both in its complete ſtate, and in conjunction with the planes of other modifications, is of moſt frequent occurrence in the cryſtals of calcareous ſpar. We ſhall mention the more intereſting varieties.

When, in the progreſs from the primitive rhomboid into this dodecahedron, only ſmall planes of the former remain at the top of the pyramid, it is the chaux carb. *binaire* of Haüy (pl. 24. fig. 11.) The complete dodecahedron is ſtill more common than this; it is ſometimes found with planes of the pyramids unequal, and not meeting in a point; alſo as macle. Combined with ſmall planes of No. 2, it is Haüy's chaux carb. *biſalterne* (pl. 25. fig. 23); which likewiſe occurs as macle. When the planes of the priſmatic variety are more conſiderable than in the juſt-mentioned variety, and, conſequently, hexagonal, it is the chaux carb. *priſmée* of Haüy (pl. 25. fig. 24.); this is very common. If, in addition to the latter, ſmall planes of No. 4. are ſeen, it is the chaux carb. *analogique priſmée* of Haüy (pl. 26. fig. 35.); from which the chaux carb. *analogique disjointe* (Haüy, pl. 26. fig. 38.) only differs in the magnitude of the planes of Nos. 4 and 36. The combination of Nos. 2, 4, and 36, is alſo ſometimes ſeen in the ſhape of that beautiful macle called "heart-ſhaped calcareous ſpar," and explained and figured by M. de Bournon. The priſm of No. 2, having planes of this 36th modification, together with remains of the primitive planes at the ſummits of the pyramid, is Haüy's chaux carb. *bilinaire* (pl. 25. fig. 26.) In combination with the priſm of No. 1, and with Nos. 1 and 37, this dodecahedron is ſeldom found; in the latter the line which ſeparates the pyramidal planes from the priſm is ſometimes imperceptible, ſo that the cryſtal appears compoſed of curvilinear planes.

A variety, remarkable on account of its ſimplicity, is the chaux carb. *analogique* (Haüy pl. 26. fig. 34.); it is likewiſe compoſed of the planes of this modification, and thoſe of Nos. 2 and 4, forming altogether a cryſtal of 24 trapezoidal planes, not unlike thoſe of the leucite, except that in the former the planes are of three different dimenſions.

This modification is alſo often ſeen in combination with the planes of No. 11; the variety in which theſe latter have much increaſed in ſize at the expence of the former, is Haüy's chaux carb. *binoternaire* (pl. 25. fig. 25.); the ſame cryſtal is alſo obſerved as macle. A ſimilar variety, but which contains alſo narrow planes of Nos. 4 and 17, is the chaux carb. *doublante* of the ſame cryſtallographer, (pl. 27. fig. 47.)

The pyramidal variety of this modification with planes of Nos. 17 and 11, is Haüy's chaux carb. *progreſſive* (pl. 27. fig. 41.); and a ſimilar one, but with the planes of No. 2 inſtead of 11, is the ſame author's chaux carb. *emouſſée* (pl. 26. fig. 40.); the latter occurs alſo as macle.

Many more combinations of the planes of this modification, with thoſe of others, are deſcribed and figured by count Bournon; among others a cryſtal, compoſed of ſeven modifications, contains, in all, ſixty planes, and another, compoſed of eleven modifications, exhibits no leſs than 96 planes. The ſame author has illuſtrated this modification by 129 figures.

37. *Acute pyramidal dodecahedron of* 40° 14′.—Though the dodecahedron of this modification is conſiderably more acute than that of the preceding modification; yet it appears to have hitherto been confounded with it. It has been found in combination with the planes of the primitive rhomboid, and thoſe of Nos. 36, 2, and 11, and alſo in its complete ſtate. The cryſtals exhibiting this modification are pretty large. They have been found only in the Dauphiné Alps of Loiſan, and in Derbyſhire.

38. *Pyramidal dodecahedron of* 37° 5′.—This might eaſily be miſtaken for the dodecahedron of the preceding modification. It has not yet been obſerved in its complete ſtate, but

in combination with the planes of Nos. 2, 3, 15, 17, 22, and with remains of the planes of the primitive rhomboid. Has been found in Hungary, and other places; but does not appear to occur in England.

39. *Pyramidal dodecahedron of* 29° 58'.—The complete dodecahedron occurs in Germany; nearly complete, with planes of No. 17 at the points of the pyramids, it is Haüy's chaux carb. *ſexduodécimale* (pl. 25. fig. 22.); with the ſummit intercepted by N° 3, and with trapezoidal planes of No. 2, it conſtitutes the ſame cryſtallographer's chaux carb. *octodécimale* (ib. fig. 31.); its planes are alſo ſeen in his chaux carb. *zonaire* (pl. 26. fig. 39.) in combination with thoſe of No. 1, and of No. 17, which latter are the characteriſtic planes. Alſo the variety deſcribed by Haüy under the name of *quintiforme*, (Ann. du Muſ. vol. ii.) has ſmall planes of this 39th modification, which has hitherto been found principally in Germany.

40. *Acute pyramidal dodecahedron of* 26° 34'.—This dodecahedron is not unfrequently ſeen in its complete ſtate, but its points, on account of their great fragility, are generally broken. It occurs in Germany, from which country, and from Derbyſhire and Cumberland, are alſo procured groups of cryſtals, including the planes of this modification, in combination with others, ſuch as Nos. 1, 2, 3, 17, 19, 21, 22, 39, and 50.

41. *Acute pyramidal dodecahedron of* 15° 53'.—This is the laſt, and at the ſame time the moſt acute, of the ſeries of pyramidal dodecahedrons produced by a decrement along the edges of the baſe of the primitive rhomboid, and conſequently with cleavage at the ſummit on the more obtuſe edges of the pyramid. This dodecahedron occurs complete, but, on account of its great fragility, is generally ſeen in a broken ſtate; ſometimes two oppoſite planes of the pyramid, having increaſed in ſize, ſo that they meet no longer in a point, give riſe to cuneiform pyramids. Nor is it uncommon to ſee four oppoſite planes in the ſame caſe. Such cryſtals bear great reſemblance to certain varieties of arragonite, from which they are, however, eaſily diſtinguiſhed by their much greater fragility, and by their lamellar ſtructure. It has been obſerved with veſtiges of the primitive planes, and in combination with thoſe of ſeveral other modifications: in one cryſtal there are no leſs than 60 planes, being the reſult of ſeven different modifications. The cryſtals exhibiting planes of this modification are moſtly found in Cumberland, Derbyſhire, and on the Hartz.

42. *Acute pyramidal dodecahedron of* 67° 55'.—With this begins the ſeries of thoſe dodecahedrons which are the reſult of a decrement of the laminæ at the acute angles, on the baſe of the primitive rhomboid. Hence the cleavage takes place at the ſummit on the leſs obtuſe edges. Is found in its complete ſtate, and combined with the planes of Nos. 36, and 36 and 2, in Derbyſhire; but belongs to the more ſcarce modifications of calcareous ſpar.

43. *Acute dodecahedral pyramid of* 62° 36'.—This has been found in a complete ſtate in Derbyſhire, where, as well as in Cumberland, it occurs alſo combined with the planes of ſeveral other modifications, forming, in ſome inſtances, very complicated cryſtals, ſuch as that of fig. 476 in the work before us, the 102 planes of which are the reſult of eleven modifications.

44. *Acute dodecahedral pyramid of* 61° 47'.—Though the ſolid angle of the ſummit of this dodecahedron differs but little from that of the preceding modification, yet there is a great difference in the inclination of their planes: in the preceding dodecahedron theſe meet each other under three angles of 158° 22', and three others of 96° 40', while in this 44th modification they meet three of them under an angle of 140° 42', and three under one of 112° 44'. The complete dodecahedron of this modification is ſcarce, but occurs in Derbyſhire. In combination with the planes of other modifications, particularly with Nos. 2 and 14; 2, 14, and 47; 2, 4, and 50, it is found in Derbyſhire and Cumberland; and combined with planes of ſeveral other modifications, count Bournon has ſeen it among the cryſtals of calcareous ſpar that accompany the ſilver ores of Potoſi; one of theſe cryſtals, the reſult of eight modifications, has 66 planes.

Haüy's chaux carb. *numérique* (I. des Min. No. 106.) approaches very near this modification in the meaſurement of its angles.

45. *Acute pyramidal dodecahedron of* 56° 30'.—Might eaſily be miſtaken for the dodecahedron, No. 36, in which, however, the cleavage takes place on the more obtuſe edges. The dodecahedron in its complete ſtate has been found in Derbyſhire, where this modification occurs in combination with the planes of ſeveral others; the moſt complicated among them is a cryſtal, produced by ten modifications, five of which belong to rhomboids, and four to dodecahedrons, which, together with the planes of the priſm No. 2, form a cryſtal of 84 planes.

46. *Acute pyramidal dodecahedron of* 49° 23'.—Reſembles the dodecahedron, No. 43, with regard to the inclination of its planes to each other; but it is much more acute. On the other hand it approaches near the dodecahedron, No. 36, in the meaſurement of the ſolid angle of its ſummit; but in this the inclination of the planes is different, not to mention the difference in the cleavage. This dodecahedron in its complete ſtate is very ſcarce, it has, however, been found in Derbyſhire and Cumberland; the combinations of its planes with thoſe of other modifications, ſuch as Nos. 1, 2, 3, 4, 6, 17, 36, and thoſe of the primitive rhomboid, are more frequently met with in thoſe parts of England.

47. *Acute pyramidal dodecahedron of* 45° 2'.—This appears to be peculiar to the ſame places, in which the cryſtals with the planes of the preceding modification are found. The complete dodecahedron is ſeldom ſeen. It is moſt frequently found in combination with the priſm No. 2: the angles of three alternate edges being very obtuſe, its pyramid appears almoſt triangular. Theſe cryſtals are in general very tranſparent and beautiful.

48. *Acute pyramidal dodecahedron of* 44° 30'.—This is but little more acute than the dodecahedron of the preceding modification; but the planes of the latter meet each other, three under an angle of 163° 50', and three under one of 84°; while in this 48th modification the ſame planes meet three under 150° 8', and three under 97° 12'. The dodecahedron in its complete ſtate has not yet been found. Its planes occur in cryſtals from Cumberland and Derbyſhire, in combination with thoſe of Nos. 2, 14, 32, 36, and 45.

48*. *Acute pyramidal dodecahedron of* 41° 31'.—The planes of this modification are thoſe marked *x* in the figures of Haüy's chaux carb. *paradoxale* (pl. 27. fig. 42.), *deloſique* (ib. fig. 46.), and *complexe* (ib. fig. 43.)

49. *Acute pyramidal dodecahedron of* 39° 9'.—The dodecahedron of this modification in its complete ſtate is from Hungary. Combined with the planes of ſeveral other modifications, it occurs principally in Derbyſhire; one of the cryſtals from thence, figured by count Bournon, is compoſed of 90 planes, being the reſult of nine modifications.

50. *Acute pyramidal dodecahedron of* 25° 25'.—To this probably belong the pyramidal planes of Haüy's chaux carb. *acutangle*. This modification has hitherto been principally found on the Hartz, it occurs however alſo, combined with the planes of ſeveral others, in Derbyſhire and other parts

of England; the cryſtals that exhibit its planes frequently accompany ſtalactitical carbonate of lime. The complete dodecahedron has not yet been found.

51. *Acute pyramidal dodecahedron of* 14° 30′.—The planes of the very acute pyramids of this modification are of rare occurrence; and in its complete ſtate the dodecahedron has not been ſeen at all. The cryſtals from Derbyſhire, on which its planes have been obſerved, are the reſults, ſome of ſix, others of ſeven and eleven, different modifications.

52. *Acute pyramidal dodecahedron of* 18° 26′.—Though this and the two following dodecahedrons are, like thoſe of the preceding modifications, the reſult of an intermediate decrement of the cryſtalline laminæ on the acute angles of the planes at the baſe of the primitive rhomboid, yet they differ from the latter in the cleavage, which takes place on their more obtuſe edges. This dodecahedron has not yet been found in its complete ſtate; in combination with the planes of ſeveral other modifications, of which thoſe of No. 36 are the moſt conſiderable, it is found in Derbyſhire.

53. *Acute pyramidal dodecahedron of* 16 35′.—M. de Bournon has obſerved the planes of this modification only in two cryſtals from Saxony, where they ſometimes accompany red ſilver ore. This is undoubtedly the ſcarceſt of all modifications of calcareous ſpar, and one of the few that are not found in England.

54. *Acute pyramidal dodecahedron of* 14° 4′.—This is the moſt acute of all dodecahedrons hitherto obſerved in calcareous ſpar. It differs but little in this reſpect from that of No. 51; but independently of the conſiderable difference in the reſpective inclination of their planes to each other, the cleavage of the former is on the leſs obtuſe edges, while that of this modification takes place on the moſt obtuſe edges. M. de Bournon has obſerved the planes of this modification in two varieties only; the one is the dodecahedron in its complete ſtate; the other exhibits its planes combined with thoſe of No. 13, which latter happens to be the moſt acute of all rhomboids hitherto obſerved of this ſubſtance. Both varieties were found in Weſtmoreland.

55. *Acute pyramidal dodecahedron of* 34° 12′.—This dodecahedron, like thoſe of Nos. 25 and 31, is compoſed of iſoſceles triangles. Count Bournon has obſerved this rare modification in a few cryſtals from Derbyſhire, in combination with the planes of the primitive rhomboid, and thoſe of Nos. 2 and 4.

IV. *Dodecahedral priſmatic Modification.*

56. *Dodecahedral priſm formed at the ſolid angles of the baſe.* (not before deſcribed) Its planes are produced by a retrogradation of the cryſtalline laminæ on the ſolid angles, ſo as to replace each of them by two planes which meet under an angle of 142° 2′. Its planes are found combined with thoſe of the hexahedral priſm No. 2, which give the cryſtal the form of a priſm of 18 ſides; in other cryſtals which, beſides the juſt mentioned planes, compriſe alſo thoſe of No. 1, the priſm is compoſed of 24 ſides. It has been likewiſe found in combination with the planes of ſix different modifications, four of which belong to dodecahedrons, one to the priſm of No. 2, and one to No. 56, producing in all 66 planes. Another variety has been obſerved by count Bournon, which, in addition to the planes of the laſt-mentioned variety, contains alſo thoſe of the priſm No. 1, and is conſequently compoſed of 72 planes. This modification, which has been found in Cumberland, is rare, but it is not improbable that its planes may be thoſe of ſeveral of the curvilinear varieties already mentioned, but which cannot be determined by the goniometer.

The cryſtals of calcareous ſpar are variouſly aggregated, and often ſo deeply imbedded, that their ſummits only are viſible. They occur of all degrees of magnitude, from minute to 14 inches in length; their ſurface is generally ſmooth, ſometimes ſtreaked or druſed. Externally from ſhining and ſplendent, to dull, ſometimes pearly; internal luſtre from ſplendent and ſpecularly ſplendent, to ſhining and gliſtening: it is moſtly a vitreous luſtre, the intenſity of which is generally in proportion with the tranſparency of the cryſtal.

Fracture foliated, rarely curved foliated; fragments rhomboidal. The maſſive is generally found in large-grained diſtinct concretions, but alſo ſometimes in teſtaceous, wedge-ſhaped, and diverging, more or leſs ſtreaked priſmatic concretions.

Tranſparency both of maſſive and cryſtallized calcareous ſpar is various; the former is however generally only tranſlucent, while the cryſtals are moſtly ſemi-tranſparent and tranſparent; and theſe poſſeſs the double refraction in a high degree.

It is ſemi-hard, between gypſum and fluor ſpar, or, (as count Bournon characteriſes its hardneſs,) juſt ſcratched by common braſs. It is brittle, eaſily frangible.

Specific gravity 27.17 as a mean. Bourn.

Some varieties, eſpecially that of browniſh-yellow colour, and part of thoſe found in the ſhell marble of Derbyſhire, are phoſphoreſcent when laid on a hot coal. The ſame quality has been obſerved, by Schumacher, in varieties from Norway.

Its chemical characters agree with thoſe of the preceding ſub-ſpecies. The pureſt Iceland ſpar is compoſed of

Lime	55 0		55.5	
Carbonic acid	34.0		44.	
Water	11.0		0.5	
	100	Bergm.	100.0	Phillips Phil. Mag. xiv.

This ſub-ſpecies is found in moſt parts of the world; but moſt abundantly it occurs in England (where almoſt all modifications have been found), in Saxony and France. Certain cryſtal forms appear to be peculiar to certain countries or localities; but this requires farther obſervations.

With regard to the Iceland ſpar it ſhould be remarked, that this very pure maſſive variety of calcareous ſpar, is far from being peculiar to that iſland; at Pergine, in Italy, as we are told by Buch, the ſame occurs in mica ſlate, as maſſes ſufficiently large to be cleft into rhomboids of upwards of two feet in length.

Calcareous ſpar is, almoſt without exception, the production of particular repoſitories; it is never ſeen to form independent beds or ſtrata. It occurs venigenous in the rocks of almoſt all formations; in the oldeſt; in Switzerland and the Pyrenees, it is accompanied with feldſpar, rock-cryſtal, &c. Alſo frequently in various metalliferous veins in gneiſs, mica ſlate, clay ſlate, ſienite, porphyry, more ſeldom in granite, frequently in grauwacke, and with ores of cobalt and copper, in the older fletz lime-ſtone. The newer fletz lime-ſtone is ſometimes traverſed by veins entirely compoſed of calcareous ſpar.

The minerals uſually accompanying calcareous ſpar are granular and compact lime-ſtone, brown ſpar, quartz, feldſpar, barytes, fluor ſpar, clay ſlate, chlorite, iron and copper pyrites, ſpathoſe iron, brown iron-ſtone, galena, blende, grey copper ore, malachite, &c.

3. *Fibrous lime-ſtone.*

This ſub-ſpecies is divided into two kinds, *a*, common, and *b*, ſtalactitical fibrous lime-ſtone (*Kalkſinter*, Wern.)

A. *Common fibrous lime-ſtone Gemeiner faſriger kalkſtein*, Wern. *Satin ſpar.*

Its colours are white, greyiſh, reddiſh and yellowiſh-white.

It occurs maſſive.

Internally it is between gliſtening and ſhining, with a pearly or ſatiny luſtre.

Croſs-fracture compact ſplintery; longitudinal fracture ſtraight or waved, fibrous; the fibres (which may be conſidered as indeterminable cryſtals) are either ſtrongly adhering to each other, and parallel, or partly detached, and tapering; they have alſo been ſeen reticularly aggregated. Fragments in moſt varieties ſplintery, alſo flattened fibrous; ſtrongly tranſlucent. Hardneſs rather leſs than that of calcareous ſpar, which it reſembles in the remainder of its characters.

Its conſtituent parts were found by Mr. Pepys to be

Carbonic acid	47.6	
Lime	50.1	
Water and loſs	2.3	
	100.0	Phil. Mag. xij.

It is a product of veins.

The fineſt variety of fibrous lime-ſtone is that of Cumberland, to which the name of ſatin ſpar is peculiarly applicable. It forms veins or *trums* of a few inches thick, in a calcareous clay; the ſalbands or liſts of theſe ſmall veins are thin layers of a blackiſh clay ſlate mixed with iron pyrites. This variety, which has ſometimes a beautiful pale roſe red tint, and perfectly pearly luſtre, is cut and poliſhed, and employed for inlaid and other ornamental works; when cut en cabochon, it ſometimes paſſes for white cat's-eye, a name which is alſo ſometimes erroneouſly, ſometimes fraudulently, given to pieces of fibrous gypſum, cut in the ſame manner.

M. de Bourbon has deſcribed a pretty variety of this ſubſtance from Matlock in Derbyſhire; it forms a very light, cellular maſs, in which the fibres, of a yellowiſh-grey colour, croſs and decuſſate one another ſo as to form the ſame kind of net which is ſeen in ſome fibrous zeolites. A variety with detached parallel fibres, which forms ſmall veins of an inch or two in thickneſs, is mentioned by the ſame author as occurring in ſhell-lime-ſtone; its fibres, of a yellowiſh-brown colour, are very delicate, and ſeparable from one another by the ſlighteſt touch. A variety with detached diverging fibres is found at Schemnitz in Hungary.

B. *Stalactitical fibrous lime-ſtone. Kalkſinter*, Wern. *Stalactite* or *Sinter*.

Its more common colours are ſnow, greyiſh and yellowiſh-white, which latter paſſes into wax and honey yellow, and yellowiſh-brown; leſs common are the green varieties of colour, ſuch as ſiſkin, piſtachio, aſparagus, mountain, and verdigris green, which latter paſſes into ſky blue; ſometimes, though rarely, it is fleſh, or peach-bloſſom red, and reddiſh-brown. When ſeveral of theſe colours occur in the ſame piece, they are in ſtripes, ſometimes running into each other, at other times perfectly diſtinct.

It occurs maſſive, tubular, reniform, globular, botroidal, coralloidal, ſtalactitic, and tuberoſe. Its ſurface is generally rough, or druſy, with minute indeterminable cryſtals; internal luſtre commonly glimmering, and pearly.

Fracture from very delicately to coarſe fibrous; fibres generally ſtraight, ſtellularly diverging, or parallel. Fragments cuneiform and ſplintery, alſo indeterminately angular. It generally occurs in curved lamellar diſtinct concretions, parallel to the external ſurface.

It is more or leſs tranſlucent, paſſing into ſemi-tranſparent. The remaining characters are thoſe of calcareous ſpar.

Specif. grav. 2.325—2.876, Briſſon; 2.741 (yellowiſh-white from Poland), Kirwan. This muſt of courſe vary according to the different degrees of purity.

Stalactitical fibrous lime-ſtone is generally found in caves, crevices, and old ſhafts, in tranſition, and fletz lime-ſtone, hanging from and covering the roofs, walls, and floors of the caves, and thus producing groups of figures, which fancy readily transforms into ſtatues, pillars, pulpits, fonts, &c. The moſt celebrated ſtalactite caves are, the grotto of Antiparos in Greece, the Baumar's hole on the Hartz, the caves of Baden, thoſe of Orenburg and Nertſhinſk in Siberia, thoſe of Matlock in Derbyſhire, of Yorkſhire, Auxelles, d'Arcy, de la Balme in France, &c.

The maſſive variety of this ſubſtance, produced by the trickling down from the roof and walls, and covering the floor of caves, is ſometimes diſtinguiſhed from ſtalactite by the appellation of *ſtalagmites*.

Sometimes the conical or cylindrical ſtalactites are terminated by a ſmall cryſtal.

The common varieties are uſed for burning to lime; the finer ſorts are employed by the ſtatuary and maſon, in countries where they occur in large maſſes. They are called *marmo alabaſtrino* by the Italians. See Marble.

The beautiful coral-like calcareous ſubſtance, called *flos ferri*, and commonly referred to ſtalactitical fibrous lime-ſtone, is a variety of *arragonite*.

4. *Pea-ſtone. Erbſenſtein*, Werner. *Pierre de pois ou Piſolite*, Broch.

Its principal colour is yellowiſh, reddiſh, and greyiſh, leſs frequently ſnow-white; the yellowiſh paſſes through yellowiſh-grey into cream yellow and yellowiſh-brown.

It occurs commonly maſſive, but alſo reniform and botroidal.

Internally it is dull. Fracture even. Fragments indeterminately angular.

It is compoſed of ſpherical diſtinct concretions, which are again compoſed of thin concentric lamellæ. Theſe globules are generally connected either by a calcareo-ferruginous cement, or they are detached; their ſize varies from that of a pea to that of a hazel-nut.

It is opaque, ſeldom rather tranſlucent on the edges. Soft; brittle; eaſily frangible.

Specific gravity 2.396, Wiedenmann.

Its chemical characters and conſtituent parts appear to be thoſe of the preceding ſub-ſpecies.

The principal locality of pea-ſtone is Carlſbad in Bohemia. A handſome variety, conſiſting of detached globules, which are generally compoſed of fine granular diſtinct concretions, is found at the baths of St. Philip in Tuſcany, and known by the name of *confetto di Tivoli*. Pea-ſtone is alſo ſaid to occur in Hungary and Sileſia.

Several opinions have been broached to account for the origin of theſe globular concretions, each of which is furniſhed with a nucleus of various dimenſions, but generally very minute; it is ſometimes a ſmall angular or rounded grain of quartz, or a particle of ſlate; and even ſmall fragments of granite have been ſeen in the centre of theſe globules. This circumſtance points out the only poſſible manner in which theſe concretions can have been produced. The ſmall bodies which ſerve as nucleus to each globule, muſt have been raiſed by, and kept floating in the agitated water of the ſprings, which being highly impregnated with calcareous particles, gradually depoſited round each of them the concentric laminæ; the globules thus produced afterwards ſunk to the bottom, where, according as circumſtances permitted it, they either remained unconnected, or were cemented into ſolid beds, ſuch as they are ſeen near the hot ſprings of Carlſbad.

The ſimilarity which ſome writers find between the pea-ſtone and the variety of compact lime-ſtone, called roe-ſtone, is not found in reality.

Lime may be obtained in a ſtate of abſolute purity, by ſeveral proceſſes from the native ſubſtances containing this earth. The analyſis of the carbonats of lime is by far the moſt ſimple, eſpecially when no other earth or metallic oxyd is preſent. This is pretty much the caſe with ſeveral of the marbles, particularly the white or ſtatuary marble. If the lime in any of theſe ſubſtances be combined with no other acid but the carbonic, let 100 grains in fine powder be diſſolved in muriatic acid. If there be any reſiduum, it may be conſidered as ſilex, or ſome ſalt of lime not decompoſable by the muriatic acid, and muſt be ſet apart. Add to the muriatic ſolution as much pure ammonia as will make it ſmell of this alkali, and all the earths, excepting lime, with metallic oxyds, if there be any, will be precipitated, leaving the lime in ſolution. If no ſubſtance be ſuſpected which is ſoluble in ammonia, the lime may be conſidered as ſeparated from the other ſubſtances, and if ſuch a ſuſpicion ſhould exiſt, the ſubſtance may be ſeparated by adding only juſt as much ammonia as will make the ſolution neutral. The lime may be precipitated from the acid with carbonat of potaſh, or that ſalt commonly called the ſub-carbonat, by which a carbonat of lime is obtained. This white powder, being ſeparated, muſt be expoſed to a ſtrong heat in a platina crucible, to ſeparate the carbonic acid, which leaves the lime in a ſtate of purity. The precipitates by the ammonia may conſiſt of magneſia, iron, and ſometimes manganeſe. The magneſia and manganeſe will be diſſolved by adding a ſolution of ſuper-carbonat of potaſh, leaving the oxyd of iron behind, which muſt be waſhed and dried. The manganeſe may be precipitated by the hydro-ſulphuret of potaſh in a ſtate of ſulphuret of manganeſe, which being waſhed, dried, and expoſed to a ſtrong heat in a platina crucible to expel the ſulphur, will leave the pure oxyd of manganeſe. The magneſia, which is yet held in ſolution by the exceſs of carbonic acid, may be finally precipitated by pure potaſh. The precipitate, being ſeparated, may be expoſed to a ſtrong heat in a platina crucible, which will give this earth in a ſtate of purity. The reſulting ſubſtances, on being weighed, will not amount to the original weight of the lime-ſtone; for, independent of the loſs by analyſis, allowance muſt be made for the loſs of carbonic acid and water. The total amount of the latter ſubſtances may be known, by expoſing a given weight in powder in a platina crucible. The loſs by weight will be carbonic acid and water. If the carbonic acid alone be required, let a given weight in powder be taken, and let a quantity of dilute ſulphuric acid, amply ſufficient to ſaturate all the ſubſtances, be accurately weighed; then let the acid and powder be mixed together, and ſtirred till the efferveſcence ceaſes: afterwards weigh the maſs; the loſs of weight will be carbonic acid. The ſame may be aſcertained by putting the powder into a gas bottle, and adding muriatic acid by degrees from an acid holder, and then collecting the gas in lime-water. The carbonat of lime ſo collected being weighed, 45 of carbonic acid may be allowed for every 100 of the carbonat.

The example given is ſuppoſed to be the moſt complicated of the carbonats of lime.. If ſilex be a component part, it will be ſeparated in the firſt ſolution, and muſt be waſhed and dried. Manganeſe is ſeldom found in lime-ſtone. It is ſaid to conſtitute the property which ſome lime has of ſetting under water.

The native ſulphat of lime or gypſum may be analyſed by the following proceſs. Let a hundred grains of the cryſtallized ſalt, in fine powder, be expoſed to a red heat for ſome time: the loſs by this treatment is the water of cryſtallization. Let the powder, after weighing, be boiled for ſome time in a ſolution of pure carbonat of potaſh, by which is obtained a carbonat of lime, and a ſulphat of potaſh, the latter being ſoluble, and the former inſoluble. To the ſulphat of potaſh, when ſeparated, add muriat of barytes, and the ſulphuric acid will be precipitated combined with the barytes. For every 100 of this ſalt, allow 33.3 of acid, by which the proportion of ſulphuric acid will be known.

The inſoluble matter firſt produced will conſiſt of carbonat of lime, and perhaps iron. By adding to this the ſupercarbonat of potaſh, the whole of the lime will be diſſolved, but the oxyd of iron will be left behind.

The lime which is diſſolved by the ſuper-carbonat of potaſh may be precipitated in the ſtate of carbonat, and made pure by a ſtrong heat in a platina crucible, to drive off the carbonic acid.

Phoſphate of lime is analyſed by diſſolving the native cryſtals in nitric acid, and adding to the ſolution acetat, or nitrat of lead, till no more is precipitated: the ſubſtance is the phoſphat of lead, which being ſeparated and weighed, will determine the quantity of phoſphoric acid, by allowing 18.4 of acid for every 100 of the phoſphat of lead. The lime which is diſſolved in the nitric acid may be precipitated by carbonat of potaſh.

The fluat of lime may be analyſed by firſt boiling it in a ſtate of fine powder with carbonat of potaſh, or ſoda, by which a fluat of potaſh or ſoda is obtained, from which the fluoric acid may be again precipitated by acetat or nitrat of lead, from which the proportion of fluoric acid may be obtained

The firſt reſiduum, which is carbonat of lime, and generally oxyd of iron, muſt be treated as in the analyſis of ſulphat of lime, to ſeparate the oxyd of iron from the lime.

The native borat of lime contains more magneſia than lime; for its analyſis, ſee the *Borat of Magneſia.*

Chemical Properties of Lime.—To obtain lime in a pure ſtate, the moſt perfect cryſtals of the carbonat ſhould be put into a covered veſſel, and expoſed to a ſtrong heat, conſiderably above redneſs, for ſeveral hours. The cryſtals will retain their ſhape, but will have loſt their tranſparency, and become beautifully white. By this proceſs the carbonic acid and water of cryſtallization are expelled, leaving the lime in a ſtate of purity.

The lime thus obtained has a cauſtic alkaline taſte, and like bodies of thoſe qualities, to a certain degree, deſtroys the texture of the ſkin, and in other reſpects acts upon animal ſubſtances in general: it alſo changes vegetable blues to green. Its ſpecific gravity is various; according to Kirwan it is 2.3. In this ſtate it is called quick-lime. Its hardneſs, immediately after it is produced from the carbonat, is not much diminiſhed; but if expoſed to the air for a certain time, it falls into an impalpable powder, which appears of a more ſplendid white than in the ſolid ſtate.

In aſſuming this form by expoſure, it is found to be heavier by one-third of its original weight. For this fact we are indebted to Mr. Dalton, who terms lime in this ſtate an *hydrat of lime.*

If it be expoſed to the air a longer time, it combines with carbonic acid, and would ultimately acquire the original weight of the carbonat.

When water is poured upon newly burned lime, it quickly ſwells with a hiſſing noiſe, abſorbing the water with great avidity, while much heat and even light are evolved.

Theſe phenomena do not ceaſe till it has abſorbed one-third of its weight: in this ſtate it is called *ſlacked* lime.

Many other ſubſtances are capable of furniſhing lime in a ſtate of tolerable purity. Of theſe are the ſtalactite of Derbyſhire, chalk, white marble, and ſome of the other marbles.

Lime is not fuſed by the greateſt heats hitherto produced, although it is ſuſceptible of fuſion by very ſlight admixture of ſome earths and metallic oxyds.

The change which takes place in all thoſe bodies which afford lime by burning, was not explained before the diſcovery of carbonic acid by Dr. Black. The peculiar qualities of quick-lime were ſuppoſed by Boyle and by Newton to ariſe from the fire fixed in it by the proceſs of burning. Others ſuppoſed its cauſticity to ariſe from the preſence of an acid formed by the heat. Dr. Black, however, demonſtrated that the qualities of lime were not to be attributed to the preſence of any ſubſtance in lime, but to the abſence of water and carbonic acid, the latter of which he at the ſame time diſcovered.

If lime be added to water at 60°, it diſſolves about .005 of its weight. It appears from the experiments of Dalton, that cold water diſſolves more lime than hot; a property not common to other bodies. According to this ingenious chemiſt, water at 60° diſſolves $\frac{1}{778}$ of its weight; at 130°, $\frac{1}{972}$ part; and at 212°, $\frac{1}{1270}$ part.

The ſolution of lime in water is commonly called *lime-water*. When lime-water is expoſed to the air, it ſoon becomes covered with a pellicle, exhibiting the priſmatic colours, which gradually thickens into a cruſt, and by its weight falls to the bottom of the liquid. This has been called the cream of lime. It is produced by the lime combining with the carbonic acid of the atmoſphere, by which it becomes inſoluble, and is ſeparated from the water.

The ſame ſeparation takes place by breathing through lime-water, from the preſence of the carbonic acid afforded by reſpiration.

Lime combines with ſeveral of the combuſtible bodies, forming peculiar compounds. When two parts of lime and one of ſulphur are heated together in a crucible, they unite in forming a reddiſh maſs, which is the ſulphuret of lime. When this compound is moiſtened with water, the latter is decompoſed. One portion of the hydrogen of the water unites with a portion of ſulphur, and eſcapes under the form of ſulphuretted hydrogen gas. Another portion combines with a part of ſulphur and lime, forming a triple compound of ſulphur, hydrogen, and lime, called an hydroguretted ſulphuret of the earth, while the oxygen of the decompoſed water, with the remainder of the ſulphur and lime, forms the ſulphat of lime.

The hydroguretted ſulphuret of lime is of a greeniſh-yellow colour. If expoſed to the air for ſome time, it gradually abſorbs oxygen, and is converted into ſulphat of lime. If, however, it be kept in ſolution in water in a cloſe veſſel, ſome of the ſulphur gradually precipitates, leaving in ſolution the hydroſulphuret of lime. See *Sulphuretted* HYDROGEN.

The hydroguretted ſulphuret of lime has the property of diſſolving charcoal as well as ſome metals, and metallic oxyds.

The hydroſulphuret of lime is formed by paſſing ſulphuretted hydrogen gas through lime-water. This gas unites with the lime, forming a compound of a diſagreeable bitter taſte.

Phoſphuret of Lime.—This ſubſtance may be formed as follows: into an earthen tube about 12 inches long, or a glaſs tube coated with equal parts of ſand and pipe-clay, and cloſed at one end, put ſome pieces of phoſphorus, ſo as to lie at the cloſed end of the tube. Let the remainder of the tube be filled with bits of newly burned quick-lime, about the ſize of large peas, and then ſtop the end of the tube with a chalk or dry clay ſtopper, not fitting very tight. Let the tube be now paſſed through two holes of a portable furnace, the furnace being about ſix inches in diameter. One of the holes muſt be a little below the other, ſo as to give the tube a ſmall inclination to the horizon, the open end being higheſt. Let the middle part of the tube be heated red-hot, and then draw gradually the end containing the phoſphorus into a heat ſufficient to ſublime the phoſphorus. The vapour of the latter will now paſs through the red-hot lime, a great portion of which will combine with it, forming the phoſphuret of lime. If the vapour of the phoſphorus come too rapidly it paſſes by the looſe ſtopper, but ſo ſoon as the whole has been ſublimed, let the end be ſtopped more cloſely; and let the tube be withdrawn, keeping it well ſtopped till it is perfectly cold. The whole of the contents of the tube may now be ſhaken out, and the darkeſt coloured pieces ſelected, which muſt be kept in a well ſtopped dry bottle.

The phoſphuret of lime, thus prepared, is of a deep brown colour.

When thrown into water it does not diſſolve, but bubbles of gas are ſeen to proceed from it, which coming to the ſurface burſt, and inflame ſpontaneouſly, producing a beautiful ring of white ſmoke.

Theſe phenomena are occaſioned by the preſence of a ſubſtance called phoſphuretted hydrogen gas, which has the ſingular property of taking fire at the common temperature. The water is decompoſed by the phoſphuret. The hydrogen combines with a portion of the phoſphorus, forming the gas above-mentioned, while the oxygen of the ſame combines with the remainder of the phoſphorus, forming phoſphoric acid, which with the lime forms phoſphat of lime. Beſides this, a portion of the gas firſt combines with the phoſphuret, forming an hydroguretted phoſphuret, which, if taken from the water before it is decompoſed, and wiped dry, retains the gas. On pouring muriatic acid upon it the gas is liberated, and inſtantly inflames.

Lime does not combine with any other of the inflammable bodies, but it combines with ſeveral of the metallic oxyds.

When any of the oxyds of lead are boiled with lime and water, a portion of the oxyd is diſſolved. The ſolution, on evaporation, affords ſmall cryſtals.

This compound has the property of ſtaining wool, hair, nails, horn, and ſome other animal ſubſtances, of a deep and agreeable brown, which by expoſure to the air diſappears. This colour appears to be the brown oxyd of lead combined with the ſubſtance. An acid inſtantly diſſolves it, and the colour diſappears.

Lime alſo diſſolves the red oxyd of mercury, of the ſolution affording yellow cryſtals.

Lime has the property of combining with ſome of the other earths and metallic oxyds, forming mortars of different qualities. Dr. Higgins, in his book upon cements, propoſed the following as the beſt compoſition for common mortar: three parts of fine waſhed ſand, four parts of coarſer ſand, one part of newly ſlacked lime made up with as little water as poſſible, which he recommends to be ſoft water. Mortar, thus formed, becomes very hard in a little time, and continues to become harder for a great length of time. Hence has ariſen the miſtake, of the ancients being in ſome ſecret of making mortar, which is not known to the moderns.

A great improvement has lately been made in making cements by combining lime with oxyd of iron and manganeſe. An iron ore abounding with clay, a calcareous matter, and pyrites, have been introduced under the name of "Parker's cement," from the name of the inventor and patentee. After burning and grinding to powder, it has the property of ſetting rapidly when mixed with water, and even under water. This rapid induration can be explained, only by ſuppoſing a great affinity to exiſt between the different earths and metallic oxyds in its compoſition.

Lime had long been ſuſpected to be a compound body; but it is only lately that this fact has been verified by experiment. From the general reſemblance of the earths to the oxyds of many of the metals, Lavoiſier ſuppoſed them to be oxyds of metals, which had ſo great an affinity for oxygen as not to be reduced by ordinary means. Several unſucceſsful attempts were made to realize this conjecture by different philoſophers.

In the late experiments of Mr. Davy, in which he diſcovered the fixed alkalies to conſiſt of metallic baſes united to oxygen, this philoſopher was led to ſuppoſe that the earths, at leaſt thoſe having alkaline qualities, might be compounds of peculiar baſes united to oxygen; and in this conjecture he ſeems not to have been miſled.

Mr. Davy did not ſucceed in obtaining the metaloid of lime in a pure ſtate, as in the inſtances of potaſh and ſoda. He fuſed a portion of lime and potaſh together, and expoſed this compound to the action of the Galvanic battery, in the ſame way he had done potaſh and ſoda. He obtained by this means a metallic ſubſtance, which differed from the metal of potaſh in being leſs fuſible, and took fire as ſoon as it was formed. He ſucceeded better by moiſtening the lime, and mixing it with red oxyd of mercury. Theſe were placed upon a plate of platina, connected with the poſitive end of the battery. A cavity being made in the mixed maſs, a globule of mercury, weighing about 60 grains, was placed in it, and a connection formed between the mercury and the other end of the battery by means of a platina wire. By this means, the lime underwent decompoſition; its metallic baſe combining with the mercury. This amalgam was then diſtilled in a glaſs tube, filled with the vapour of naphtha; by which the mercury, to a certain extent, was expelled, leaving a white maſs of a metallic appearance, and of the colour of ſilver. This ſubſtance, which no doubt was the baſis of lime, had ſo great an attraction for oxygen, that Mr. Davy could not ſucceed in examining its properties before it was burned and reconverted into lime. He has given it the name of *Calcium.*

Salts of Lime.—Lime combines with the different acids, forming peculiar compounds called ſalts.

It poſſeſſes a ſtronger attraction for the acids than alumine, magneſia, or any of the metallic oxyds: hence the exiſtence of aluminous, magneſian, and metallic ſalts are incompatible with lime. Several of the ſalts of lime are found native in great abundance, particularly the carbonat and ſulphat. We rarely find a mineral water free from ſome of the ſalts of lime. They are moſtly, however, the carbonat, ſulphat, and muriat; the reſt of the native ſalts being inſoluble in water.

Sulphat of Lime.—This ſalt may be formed by diſſolving lime in the muriatic or nitric acid, and adding ſulphuric acid to the clear ſolution, till the precipitation ceaſes. The ſubſtance which falls to the bottom is the ſulphat of lime, in a ſtate of white powder. It abounds ſo plentifully in nature, that it is never manufactured for ſale. The native cryſtals are right-angled priſms, with rhomboidal baſes. It is alſo found ſometimes in cryſtals of the form of four and ſix-ſided priſms, which are generally very tranſparent. In ſome ſpecimens theſe cryſtals are very ſmall, giving the maſs a fibrous appearance. It occurs in Derbyſhire, in large ſemitranſparent maſſes, moſtly abounding with yellowiſh-brown ſtreaks, occaſioned by the preſence of iron. Great quantities of this laſt is worked into ornaments, and uſed alſo in ſculpture.

This ſalt is ſoluble in 460 parts of water at 60°.

It is not altered by expoſure to the air, at the common temperature: if, however, it be heated to ignition, it loſes its water of cryſtallization, and falls into a fine white powder. This powder, if left in the air, would re-abſorb the water, and aſſume its chemical qualities. When this powder, newly calcined, is mixed with water to the conſiſtence of pulp, it ſoon begins to ſtiffen, becomes warm, and in a little time becomes very hard. During this ſtate it expands with great force, ſo as to break very ſtrong veſſels. It admits of the moſt delicate caſts being taken by means of it. The ſudden expanſion, at the time it is loſing its liquid form, forces it into the moſt minute cavities. It is employed by artiſts for makings caſts of buſts, and different ornaments. The ſame properties render it of great value to the manufacturers of pottery and porcelain. It is uſed in ſome countries for making the floors of upper rooms, as a ſubſtitute for wood. In the laying of theſe floors, ſome idea may be given of its expanſive force when ſetting. Thin ſlips of wood, of a thickneſs equal to the expanſion of the floor, are placed between the wall and the pulpy maſs, till the time it begins to aſſume the ſolid form. Theſe ſlips are then inſtantly removed, to make room for the expanſion. If this precaution were not taken, ſo great would be the force, as to puſh out the wall in that part.

Sulphat of lime is compoſed, according to Bergman, of 46 acid, 32 baſe, and 22 water, in the 100. Kirwan's analyſis gives 59 acid and 41 baſe in the 100. Wenzel makes it 59.84 acid and 40.16 baſe.

Dalton makes the atom of lime 24, and ſulphuric acid $13 + 3 \times 7 = 34$: hence, $\frac{24 + 34}{34} = \frac{100}{58.6}$, which gives 58.6 acid, and 41.4 baſe, = 100.

This ſalt is ſaid to be uſed in America as a manure with much ſucceſs; but has not been uſed in this country.

Sulphite of Lime.—This ſalt may be formed by adding ſulphurous acid to the nitrat or muriat of lime. A white powder is precipitated, which is ſulphite of lime. This ſalt is ſoluble in 100 parts of water. It is ſlightly effloreſcent in the air, and ultimately is converted into ſulphat. When heated, ſome ſulphur is ſublimed, and it aſſumes the ſtate of ſulphat. This ſalt is compoſed of 48 acid, 47 lime, and 5 water, = 100. It has not been applied to any uſe.

Nitrat of Lime.—The nitrat of lime may be formed by adding powdered carbonat of lime to nitric acid, till the efferveſcence ceaſes. When the ſolution is evaporated to the conſiſtence of ſyrup, and placed in a very cold ſituation, ſmall needle-ſhaped cryſtals, after ſome time, will appear: the ſhape of theſe is ſix-ſided priſms. This ſalt is cryſtallizable, but with difficulty, owing to its great ſolubility; or, in other words, to its great affinity for water; and when the cryſtals are formed, they ſoon attract moiſture from the air, and diſappear.

When the ſolution is evaporated to dryneſs, and the heat continued a ſhort time, the maſs acquires the property of ſhining in the dark. This ſalt is known by the name of Baldwin's phoſphorus.

When a ſtronger heat is applied, up to ignition, the ſalt is decompoſed; the acid is reſolved into nitrous gas, oxygen, and nitrogen. It might be employed, like nitre, to obtain a tolerably pure oxygen for experiments of combuſtion. Its decompoſition by heat alſo furniſhes an elegant method of procuring lime in a ſtate of purity. The analyſis of this ſalt by Richter gives, in the 100, 63.9 acid, and 36.1 baſe. That of Kirwan gives, in the 100, 54.44 acid, 32 baſe, and 10.56 water. Dalton makes the atom of nitric acid $5.4 + 2 \times 7 = 19.4$, and concludes the ſoluble nitrats to be ſuper-ſalts: hence, $\frac{19.4 \times 2 + 24}{19.4 \times 2} = \frac{100}{58.6}$, which gives 58.6 acid, and 41.4 of lime, = 100.

Muriat of Lime.—This ſalt is generally formed in manufacturing the carbonat of ammonia. The muriat of ammonia is mixed with carbonat of lime, in a veſſel which is expoſed to a heat capable of ſubliming the carbonat of ammonia, which leaves behind the muriat of lime. It may be alſo formed by adding carbonat of lime to muriatic acid. When the ſolution is evaporated to the conſiſtence of ſyrup, and ſet in a cool place equal to 32°, it cryſtallizes into ſix-ſided priſms, terminated by pyramids. Theſe cryſtals, however, ſoon deliqueſce, from their great attraction for moiſture, and aſſume the liquid form. Reduced to a ſtate of dryneſs, it is uſed for the purpoſe of drying different gaſes.

Water at 60° diſſolves four times its weight of this ſalt; while at 100°, it diſſolves in any proportion. It diſſolves in alcohol in a great proportion, producing heat. When the dry ſalt is mixed with ſnow, it produces great cold, and is employed to great advantage in freezing mixtures. When it is expoſed to heat above ignition, ſome of the acid eſcapes, reducing it to the ſtate of ſubmuriat. In this ſtate it has the property of ſhining in the dark, and has, in conſequence, been called the phoſphorus of Homberg. It is compoſed, according to the analyſis of Bergman, of 31 acid, 44 baſe, and 25 water, in 100. Kirwan makes it 42 acid, 50 baſe, and 8 water; and Wenzel, 51 acid and 49 baſe. Dalton makes an atom of muriatic acid 22; then lime being 24, $\frac{24 + 22}{22} = \frac{100}{47.83}$: hence we have, from theſe data, 47.83 of acid, 52.17 of baſe.

Oxymuriat of Lime.—It appears that ſuch a ſalt does not exiſt, except in the dry ſtate. When it is thrown into water, it is converted into the muriat, and oxygen eſcapes.

The ſalt, which the bleachers call the oxymuriat of lime, is in fact the hyper-oxymuriat. It is made by paſſing the oxymuriatic acid gas through a mixture of lime and water, in a Woulfe's apparatus. (See LABORATORY.) The lime is at length taken up, and the liquid becomes colourleſs. It is decompoſed by the muriatic acid, affording oxygen and oxymuriatic acid. It is uſed in bleaching to a great extent. See BLEACHING.

Phoſphat of Lime.—This ſalt conſtitutes the baſis of bones, and is a component part of moſt animal ſubſtances. It may be prepared by adding muriat or nitrat of lime to phoſphat of ſoda; or, cheaper, by diſſolving the earth of bones, which is a mixture of the ſubphoſphat and carbonat of lime, in muriatic acid, and adding pure ammonia to the ſolution. The phoſphat of lime will be precipitated alone, leaving the exceſs of lime diſſolved in the acid. This ſalt is in the form of powder of a white colour; the native ſalt, which has been deſcribed, being alone capable of the cryſtalline form.

Several of the acids, but particularly the ſulphuric, decompoſe this ſalt, by taking a part of the lime, and leaving it in the ſtate of ſuperphoſphat. Phoſphat of lime is compoſed, according to the analyſis of Klaproth, of 30.5 of acid and 69.5 baſe. Fourcroy and Vauquelin make it 41 acid and 59 baſe; Richter, 45 acid and 55 baſe; and Eckeberg, 39 acid, 36 baſe, and 25 water. By Dalton's hypotheſis, the phoſphoric acid is $9 + 2 \times 7 = 23$: then, $\frac{23 + 24}{23} = \frac{100}{48.9}$, making the acid, in 100, 48.9 acid, the baſe being 51.1.

Superphoſphat of Lime.—When ſulphuric acid is added to the phoſphat of lime, the former being one-third of the latter by weight, a portion of ſulphat of lime will be formed, which will be precipitated, leaving the ſuperphoſphat diſſolved. It may alſo be formed by diſſolving 47 parts of the phoſphat in 23 parts of real acid.

This ſalt cryſtallizes by evaporation, in brilliant plates, having a pearly appearance. The taſte of theſe cryſtals is ſtrongly acid. Indeed it was once taken for the phoſphoric acid, and was diſtilled with charcoal, to obtain phoſphorus. This ſalt is now decompoſed by the acetat of lead; and the phoſphat of lead is uſed for that purpoſe, which is found a great improvement in the preparation of phoſphorus.

When this ſalt is heated in a crucible at a little more than a red heat, it fuſes; and, on cooling, aſſumes the appearance of a tranſparent glaſs, which has been called phoſphoric glaſs. Its compoſition, according to the analyſes of Fourcroy and Vauquelin, is 54 acid and 46 lime.

Fluat of Lime.—This ſalt is not a product of art, but is found native in Derbyſhire, and other counties abounding with lead. Its cryſtals are in the form of cubes.

When this ſalt is coarſely powdered, and laid upon a hot plate, a little ſhort of ignition, it gives a beautiful blueiſh light, not much unlike the flame of burning ſulphur in common air. The artificial fluat alſo poſſeſſes this property.

When the fluat of lime is expoſed to a ſtrong heat, it melts, and, on cooling, becomes tranſparent. The facility with which it fuſes, and renders other earthy ſubſtances fuſible, is taken advantage of in the reduction of lead, and other metals. Hence it has derived its name from acting as a flux.

This ſalt is decompoſed by the nitric and ſulphuric acid, by ſeizing the lime, while the fluoric acid gas is diſengaged. Guy Luſſac and Thenard have lately ſhewn, that the gaſeous form of its acid is cauſed by the preſence of ſilex; ſince, when it is diſengaged from any baſe where ſilex is not preſent, the acid aſſumes the liquid form. See SILEX.

Its analyſis, by Klaproth, is 32.25 acid and 67.75 baſe; by Dr. Thomſon, $32\frac{1}{3}$ acid and $67\frac{1}{3}$ lime.

Borat of Lime.—This ſalt may be formed by mixing the muriat of lime with a ſolution of borat of ſoda. The ſalt is precipitated in the ſtate of white powder, which is inſoluble in water: few of its properties are known.

Carbonat of Lime.—This ſalt, in the native ſtate, is the moſt abundant of all the calcareous ſalts.

Although the primitive forms of the cryſtals of it are rhomboidal priſms, this figure has been ſo differently arranged as to form a numerous variety of ſecondary forms. The neutral ſalt of this ſpecies is inſoluble in water; but it becomes ſoluble, to a certain degree, with an extra doſe of acid.

The carbonat of lime may be formed by adding carbonat of potaſh to muriat of lime. It conſiſts of 45 acid and 55 lime.

According to the experiments of ſir James Hall, when the carbonat of lime is expoſed to a red heat, in a cloſe veſſel, ſuch as a gun barrel, it melts; and, on cooling, is found to retain its original properties, with the exception of loſing ſomething leſs than 4 or 5 *per cent.* of carbonic acid.

Supercarbonat of Lime.—When the ſupercarbonat of potaſh is added to muriat of lime, a portion of lime will remain on ſolution, which is not the carbonat of lime, but a ſupercarbonat. This ſalt is very frequently found in mineral waters, eſpecially in lime-ſtone countries, and in countries abounding with marle.

A carbonat of potaſh being added to a ſolution of this ſalt, takes one doſe of acid from it to form a ſupercarbonat, and the carbonat of lime is thrown down. When the ſupercarbonat of potaſh is added, no change takes place. When lime-water is added to water diſſolving the ſupercarbonat of lime, the lime of both aſſumes the ſtate of carbonat, and fall down together.

When the ſupercarbonat of lime is expoſed to a boiling heat for ſome time, the ſecond doſe of acid is expelled, and the remaining carbonat is precipitated. This ſalt, however, is not immediately decompoſed by boiling, but requires to boil for ſome time.

Acetat of Lime.—If carbonat of lime be added to the acetic acid, an efferveſcence will take place, and the lime will be diſſolved in the acetic acid, forming acetat of lime. If the ſolution be evaporated, it affords ſmall cryſtals of a white colour, having a ſilk appearance.

It has a bitter acid taſte.

It is compoſed of 65.11 acid and 34.89 lime.

Oxalat of Lime.—This ſalt is formed by dropping the oxalat of ammonia into any ſolution of lime. It appears to be the moſt inſoluble of all the ſalts of lime. It is in the form of white powder, and is compoſed, according to Bergman, of 48 acid, 46 lime, and 6 water.

Tartrat of Lime.—If carbonat of lime be added to a ſolution of the ſupertartrat of potaſh, the exceſs of tartaric acid combines with the lime, which falls in the ſtate of inſoluble powder. It is from this inſoluble tartrat that the tartaric is obtained, by means of ſulphuric acid.

Citrat of Lime.—This ſalt, like the laſt, is formed by adding the carbonat of lime to citric acid in the lemon juice. The ſalt is the inſoluble powder which falls to the bottom. It is from this ſalt that the citric acid is obtained pure, by the ſuperior affinity of ſulphuric acid.

It conſiſts of 62.66 acid and 37.34 lime.

Pruſſiat of Lime.—The pruſſiat of lime is formed by diſſolving lime in the pruſſic acid. It is decompoſed by all the acids, and is of little permanence. The ſalt commonly, but improperly, called by this name, is a triple ſalt, containing both lime and iron. It is made by adding 56 parts of lime water to two parts of Pruſſian blue, well waſhed in hot water, boiling them for ſome time till the lime is ſaturated. The ſolution is of an olive colour, and affords cryſtals by evaporation. The ſolution of this ſalt is a valuable teſt for iron in mineral waters.

The reſt of the ſalts of lime are not of any importance, as far as we at preſent know.

The arſeniats and molybdat of lime are inſoluble in their neutral ſtate: the former is ſoluble in exceſs of acid.

Succinat of Lime is difficultly ſoluble.

Benzoat of Lime is ſoluble, and may be obtained in cryſtals.

Chromat of Lime is ſoluble and cryſtallizable.

Suberat of Lime diſſolves in hot, but little in cold water.

Camphorat of Lime is ſparingly ſoluble.

LIME, in *Agriculture*, a ſoft friable ſubſtance, obtained by calcining or burning various calcareous materials, ſuch as chalk, marble, lime-ſtone, ſhells, &c.

This is a ſubſtance which is in different ſtates, according to the particular circumſtances under which it exiſts. When newly made, from its great power of deſtroying the texture of bodies, it is termed cauſtic or quick-lime. It is alſo ſometimes called ſhell-lime or ſhells. In this ſtate, when uſed as manure, it operates with the greateſt violence, diſſipating and robbing the ſoils, to which it is applied, of their moiſture and other fluid matter: but after being expoſed to the atmoſphere for ſome time, from its property of quickly abſorbing moiſture and carbonic acid from it, it becomes mild or effete, and is termed carbonat of lime. When applied to land in this ſtate, it acts with much more mildneſs, only promoting the reſolution of the matters in which it comes in contact, by forwarding the natural proceſs of putrefaction. It has alſo leſs tendency to produce a mortary hardneſs in the poorer ſorts of clayey ſoils. But beſides theſe differences, there are others ariſing from the ſubſtances which are combined with the calcareous matters employed, as has been lately ſhewn by the ingenious experiments of Mr. Tennant, ſtated in the ſecond part of the Philoſophical Tranſactions for the year 1799. Having been informed that two kinds of lime were uſed in agriculture, which differed greatly in their effects,—one of which it was neceſſary to uſe ſparingly, and to ſpread very evenly over the land, as it was ſaid that a large proportion of it diminiſhed the fertility of the ſoil, and that, wherever a heap of it had been left on one ſpot, all vegetation was prevented for many years; and that of this kind of lime, 50 or 60 buſhels on an acre were as much as could be uſed with advantage; while of the other ſort of lime, a large quantity was never found to be injurious, and that the ſpots which were entirely covered with it became remarkably fertile, inſtead of being rendered barren:—having analyſed thoſe two kinds of lime, he found that the latter conſiſted ſolely of calcareous earth; but that the former contained two parts of magneſia, with three parts of calcareous earth. He afterwards proved, that though vegetable ſeeds would grow equally well in both theſe kinds of lime-ſtone, when ſimply reduced to powder; yet that, when they were calcined ſo as to become lime, and both of them ſtrewed about the tenth of an inch thick on garden mould, the magneſian lime prevented nearly all the ſeeds which had been ſowed from coming up, while no injury was occaſioned by the calcareous lime, when uſed under the ſame circumſtances.

It may be noticed, that this valuable diſcovery ſeems in ſome meaſure to explain the cauſe of the variety of opinion that has been maintained reſpecting the application of lime, which ſome have ſuppoſed to be of little or no advantage, and even injurious to land; which has been owing probably to their having employed the magneſian lime, or uſed it in too large proportions.

This philoſophical inquirer firſt found magneſian lime near the town of Doncaſter, and afterwards at York, at Matlock in Derbyſhire, at Breeden in Leiceſterſhire, and at Workſop in Nottinghamſhire. He aſſerts, that the cathedral and walls of York are built with this magneſian lime-ſtone; and that at Matlock the magneſian and calcareous lime-ſtones are contiguous to each other, the rocks on the ſide of the river Derwent, where the houſes are built, being magneſian, and on the other ſide calcareous. He found alſo, that in this ſituation the magneſian lime-ſtone was incumbent on the calcareous: for, in deſcending into a cavern formed in that rock, he found a ſeparate vein of calcareous lime-ſtone, which was full of ſhells, but contained no magneſia;

neſia: and concludes, that, in general, the magneſian lime-ſtone may be eaſily diſtinguiſhed from the calcareous, by its ſolution in acids being much ſlower, and that it contains generally very few ſhells; but that theſe, when preſent, are impregnated with magneſia.

In the Philoſophy of Agriculture it is remarked alſo, that all lime-ſtone may be divided into three kinds: firſt, the rocks which remain, where they were formed from ſhells beneath the ocean, except that they were afterwards elevated by ſub-marine fires; ſecondly, into alluvial lime-ſtone, as thoſe which have been diſſolved in water, and ſimply precipitated, as the beds of chalk, which contain only the moſt inſoluble remains of ſea animals, as the teeth of ſharks; and, thirdly, thoſe which, after having been diſſolved and precipitated, have been long agitated beneath the ſea, till the particles have been rolled ſo againſt each other, as to acquire a globular form, which is ſaid to reſemble the roe or ſpawn of fiſh, and which contain very few ſhells, or none, as the Ketton ſtone, and that which he has ſeen on Lincoln heath, extending almoſt from Sleaford to Lincoln. Now, ſays he, as the ſalts of the ſea conſiſt of only two kinds; common ſalt, or muriat of ſoda, and vitriolated magneſia, commonly called Epſom ſalt, which, in the ſea-waters ſurrounding this iſland, are found at a medium to exiſt in the proportion of one-thirtieth part of common ſalt and one-eightieth part of vitriolated magneſia, compared to the quantity of water; and, ſecondly, as theſe ſalts are believed by many philoſophers to have been formed by vegetable and animal matters, which principally grew upon the ſurface of the dry land, after it was raiſed out of the primeval ocean; and that, in conſequence, the ſaltneſs of the ſea was poſterior to the formation of the primeval rocks of lime-ſtone; we may underſtand why thoſe lime-ſtone ſtrata, which have not been diſſolved or waſhed in ſea-water ſince the ſea became ſalt, are not mixed with magneſia. The chalk, he ſuppoſes, muſt have been diſſolved and precipitated from water, as it exactly reſembles the internal part of ſome calcareous ſtalactites which he has in his poſſeſſion; yet there is no appearance of its component particles having been rubbed together into ſmall globules, and may not, therefore, have been removed from the ſituation where it was produced, except by its elevation above the ſurface of the ocean. But that alluvial lime-ſtone, which conſiſts of ſmall globules adhering together, called Ketton lime-ſtone, and of which there appears to be a bed 10 miles broad from Beckingham to Sleaford in Lincolnſhire, and 20 miles long from Sleaford to Lincoln, he ſuſpects may probably conſiſt of magneſian lime-ſtone; which is alſo ſaid in that country to do no ſervice to vegetation: for this alluvial lime-ſtone, by having evidently been rolled together beneath the ſea, by which the ſmall cryſtallized parts of it have had their angles rubbed off, is moſt likely to have thus been mixed with the magneſia of the ſea-water, which, as has been obſerved, is ſaid to contain one-eightieth part of its weight of vitriolated magneſia.

It is further remarked, that at the lime-works at Ticknal, near Derby, there appears a ſtratum of alluvial lime-ſtone, like Ketton lime-ſtone, which they do not burn for ſale, over the bed of the calcareous lime-ſtone, which they get from beneath the former, and calcine for ſale. It is probable, he thinks, that the ſuperior bed may contain magneſia, which has rendered it not ſo uſeful in agriculture. It is ſtill more probable that alluvial lime-ſtone has acquired its mixture of magneſia from the ſea-water; as magneſia, in its uncalcined ſtate, will precipitate lime from water, as obſerved by Dr. Alſton, who thence propoſes to render water pure and potable, which has been long kept at ſea free from putridity by having lime mixed with it, by precipitating the lime by the addition of mild magneſia.

The lime from Breedon is magneſian, that from Ticknal (which is ſold) is calcareous, he believes; and ſome farmers in the vicinity of Derby aſſert, that two loads of Breedon lime will go as far, that is, will apparently do as much ſervice to their land, as three loads of Ticknal lime. Breedon lime, he is alſo informed, is preferred in architecture, and is ſaid to go further in making mortar; which, he ſuppoſes, means that it requires more ſand to be mixed with it. In the Account of the Agriculture of the Midland Counties, lime made at Breedon, near Derby, is ſaid to be deſtructive to vegetables, when uſed in large quantities; and in Nottinghamſhire it is aſſerted, that the lime from Critch, in Derbyſhire, is ſo mild, that thiſtles and graſs ſpring up through the edges of large heaps of it, when laid in the fields. Dr. Fenwick of Newcaſtle obſerves, that the farmers in that country divide lime into hot and mild; which Mr. Tennant believes to mean magneſian and calcareous lime.

By experiments which were made by Mr. Tennant, by ſowing ſeeds of colewort on various mixtures of calcined magneſia with ſoil, and of calcareous lime with ſoil, he found thirty or forty grains of lime did not retard the growth of ſeeds more than three or four of calcined magneſia: hence, what can we conclude, but that, as they both injure vegetation in large quantities, they may both aſſiſt vegetation in ſmall ones? and that this is more probable, as the farmers believe that they find both of them uſeful, though in different quantities; and as the magneſia would form Epſom ſalt, if it met with vitriolic acid, which Dr. Home found, from his experiments, to be friendly to vegetation, when uſed in very ſmall quantities. More accurate obſervations and experiments are, however, Dr. Darwin thinks, wanting on this ſubject.

The moſt certain way to know whether any ſort of ſtone be fit for making lime is to drop upon it a little aquafortis, ſpirit of ſea-ſalt, or oil of vitriol. All ſtones on which the above, or any other ſtrong acid, efferveſces or riſes in bubbles, are calcareous ſtones, or will burn to lime; and the ſtronger the efferveſcence is, the fitter they are for that purpoſe.

And as in the uſe of calcareous matter as a manure, much depends upon its being brought into a fine powdery ſtate, it ſhould always, where fuel can be obtained at a moderate expence, be prepared by burning, as that is the eaſieſt and moſt efficacious mode of reducing lime-ſtone to powder that ever was invented, and therefore ought always to be adopted where neceſſity does not prevent it. Reducing lime-ſtone to powder by calcination is alſo, he remarks, attended with this farther advantage to the farmer, that it conſiderably diminiſhes his expence of carriage. Pure lime-ſtone loſes about two-thirds of its weight by being thoroughly burned; ſo that the man who is obliged to drive this manure from a great diſtance, will find a very conſiderable ſaving by driving it in the ſtate of ſhells; but if it were reduced to a powder by mechanical triture, he could not be benefited by this circumſtance. Many perſons chooſe to drive lime-ſtone from a conſiderable diſtance and burn it at home; but it is obvious they then ſubject themſelves to a very heavy charge in carriage, which would be avoided by an oppoſite conduct. This, therefore, ought never to be practiſed but where other circumſtances may counterbalance this unfavourable one. But as lime-ſtone is often in its native ſtate mixed with ſand in various proportions, and as ſand loſes nothing of its weight by calcination, it muſt happen that thoſe kinds of lime-ſtone which contain the largeſt proportion of ſand will loſe leaſt in calcination, and of courſe afford the weighteſt lime-ſhells.

Hence it is obvious, that thoſe who are under the neceſſity of driving lime from a great diſtance ought to be particularly careful to make choice of a kind of lime-ſtone as free from ſand as poſſible, and to drive it in the ſtate of ſhells, as they will thus obtain an equal quantity of manure at the leaſt expence of carriage that is poſſible; and the lighteſt ſhells ought, of courſe, to be always preferred. When lime is ſlaked, that which contains moſt ſand falls moſt quickly, and abſorbs the ſmalleſt proportion of water. What is pure requires a very large proportion of water, and is much longer before it begins to fall. Hence it happens that thoſe who drive ſandy lime-ſhells in open carriages, muſt be very careful to guard againſt rain, becauſe a heavy ſhower would make the whole fall, and generate ſuch a heat as to be in danger of ſetting the carts on fire; whereas pure lime-ſhells are in no danger of being damaged by that circumſtance. The writer has ſeen a cart loaded with ſuch ſhells, which had been expoſed to a continued ſhower of rain, as violent as is ever known in this country, for more than three hours, and ſeemed hardly to be affected by it in the ſmalleſt degree. He ought, he ſays, to obſerve, however, that his experiments were confined to only one kind of pure lime, ſo that it is not from hence demonſtrated that all kinds of pure lime will be poſſeſſed of the ſame qualities. Lime-ſhells formed from the pureſt lime-ſtone require more than their own weight of water to ſlake them properly; whereas, ſome kinds of lime-ſhells that contain much ſand do not require above one-fourth part of that quantity. He has found, by experiment, that pure lime-ſhells cannot be ſlaked with leſs than about one-fourth more than their own weight of water. When ſlaked in the ordinary way, the ſame lime-ſhells took more than double their weight of water.

Hence it is much worſe economy, in thoſe who have pure lime-ſhells, to ſlake and carry them home in the ſtate of powdered lime, than it is in thoſe who have only a ſandy kind of lime-ſhells to make uſe of.

It is farther ſuggeſted that it is even, on ſome occaſions, more adviſable for thoſe who have very ſandy lime, to drive it in the ſtate of powdered lime than in that of ſhells; for, as it is dangerous to give that kind of lime-ſtone too much heat, leſt it ſhould be vitrified, thoſe who burn it can never be certain that the whole of the ſtone will fall to powder when water is added, till they have actually tried it; nor do they think it a great loſs if ſome part of it ſhould be imperfectly burned, as it requires much leſs fuel on a future occaſion than freſh lime-ſtone; and therefore they much rather chooſe to err on this than on the oppoſite extreme. But ſhould any one attempt to drive this poor ſort of lime in the ſtate of ſhells, he would be in danger of carrying home many ſtones that would never fall; which would more than counterbalance the benefit he would derive from the want of the ſmall quantity of water that is required to ſlake it. On theſe accounts it is ſuppoſed it may be admitted as a general rule, that thoſe who can have acceſs to lime-ſtone which is free of ſand, will ſave a great deal in the carriage of it by driving it in the ſtate of ſhells; and that, on the contrary, it will be moſt economical, in thoſe who can only get lime of a very ſandy quality, to drive it in the ſtate of powdered lime. Hence it follows, that the practice which now prevails, of carrying ſhell-lime by water from one part of the country to another, is only an imaginary ſaving, obtained at a very high riſk, to thoſe who drive ſhells of a ſandy quality; but a real and unequivocal advantage of very high importance to the community at large, if theſe ſhells are obtained from a pure lime-ſtone. Theſe obſervations relate only to the ſaving of carriage to the farmer; which, however, is an article of great importance to him.

But there are ſome other particulars that may alſo equally affect him in this way, and in the application of the lime to his ground. A vague opinion in general prevails in every part of the country, that one ſort of lime may be more valuable than another; but it does not appear that farmers have hitherto had any rule to direct them in the choice of different ſorts of lime; ſome eſteeming one ſort ſtrongeſt, as they term it, and ſome valuing another ſort more highly, without being able to aſſign any ſatisfactory reaſon for the preference they give in either caſe. It is of importance that this matter ſhould be elucidated. Although it does not always happen, yet, in many parts of the country, the real nature of lime is ſo little underſtood, that the weightieſt lime is preferred as a manure to that which is lighter; becauſe it is imagined the firſt has more ſubſtance, and will therefore produce a more powerful effect upon ground than the fineſt and lighteſt lime. But there ſeems to be no reaſon to think there is any difference in the ſpecific gravity of different parcels of pure calcareous matter when fully calcined; therefore, if there is any difference in the weight of various ſorts of lime, it muſt ariſe entirely from a variation in the quantity or gravity of ſome extraneous matter that is mixed with the lime; and as ſand is almoſt the only extraneous body that is ever found in lime-ſtone, and is always of much greater ſpecific gravity than pure quick-lime, it follows, that the weighty lime only owes its ſuperior gravity to a larger proportion of ſand that is mixed with it. But ſand is of no value as a manure; ſo that he who voluntarily purchaſes this kind of lime in preference to the other is guilty of a great degree of folly; which will be the greater if he has likewiſe to drive it from a conſiderable diſtance.

However, thoſe farmers who have acceſs to only one ſort of lime-ſtone, muſt be contented with it, whatever may be its quality. But ſuch as have an opportunity of chooſing may be benefited by the obſervation, that pure lime-ſtone, when fully calcined and ſlaked, is reduced to a fine white impalpable powder that feels ſoft between the fingers, without the ſmalleſt tendency to grittineſs; while ſuch lime as contains ſand is never ſo fine nor ſo ſoft, but feels gritty when rubbed between the fingers. See Anderſon's Eſſays.

Action, Quantity, and Application of Lime.—The author of Modern Agriculture remarks, that there are few diſtricts where lime is not either in general uſe, or partially introduced as a manure. With reſpect to the uſe of lime, or the benefit derived from it as a mean of fertilizing the ſoil, ſome are of opinion that it promotes vegetation, by ſtimulating, or forcing the ſoil with which it is incorporated to exert itſelf: others imagine it promotes vegetation by enriching the ſoil, and thereby adding to the quantity of vegetable food. Various other opinions, different from theſe, and in ſome inſtances oppoſite to each other, have been entertained reſpecting the manner in which lime operates upon land; but all that we yet know with certainty on the ſubject, is collected from practice and experience, whereby it is proved that lime ſomehow or other operates ſo as frequently to produce luxuriant crops on ſoils which, before the application of that manure, were comparatively of little value; and farther, that on all ſoils which are treated properly after being thoroughly limed, its beneficial effects are diſcernible by the moſt curſory obſerver. Various other modes in which this ſubſtance may be uſeful as a manure, may be ſeen under the terms *Calcareous* EARTH, and PHOSPHORUS.

The proportion or quantity of lime applied to the acre ſeems hitherto, the ſame writer obſerves, fixed by no certain rule, either in regard to the nature of the different ſoils, the modes

modes of cropping afterwards adopted, or the ſuperior quality of one kind of lime-ſtone beyond another.

It has been remarked, that ſome require that it ſhould be applied in ſuch ſmall quantities as thirty or forty buſhels to the acre; and aver, that if more is uſed the ground will be abſolutely ruined; while others maintain, that ten times that quantity may be applied with ſafety. A great variation may no doubt be produced, in this reſpect, by a difference in the nature of the ſoil, in the ſtate of culture it is under at the time, in the quantity of calcareous matter with which it may have been formerly impregnated; and perhaps a variation may ſometimes ariſe from other circumſtances that have never yet been attended to. A difference will likewiſe ariſe from the quality of the lime that is applied, and from the manner in which it is employed, ſome kinds of lime containing, perhaps, ten times more calcareous matter than others: and a very great difference may proceed from the mode of applying the lime itſelf. For it is common to hear thoſe who have had little experience of lime as a manure, recommend very great caution, leſt too great a quantity be employed, for fear of burning the ſoil, as they expreſs it. This idea of burning has been evidently adopted from what is experienced by applying cauſtic lime to animals or vegetables in large quantities, as it often corrodes and ſhrivels them up, and produces other effects, which greatly reſemble thoſe of fire; but it cannot produce any ſuch effects, unleſs there are vegetables growing upon the ſoil at the time. In that caſe the vegetables might indeed be corroded by the lime, if rain ſhould fall immediately after it was ſpread when newly ſlaked; but as it loſes this fiery corroſive power in a few days after it is ſpread, nothing of that kind can be expected to happen to the ſoil. Accordingly, we never hear of crops being burnt up with too great a quantity of lime in thoſe counties where it has long been uſed as a common manure, although it is there often employed in much larger quantities than in other places where it is more rare. The writer has himſelf had the experience of lime in all proportions, from one hundred to above ſeven hundred buſhels to the acre, upon a great variety of ſoils; and has always found that its effect in promoting the fertility of the ſoil has been in proportion to the quantity employed, other circumſtances being alike. The expence, in moſt caſes, prevents farmers from employing this manure in greater quantities than thoſe above-mentioned; but accidental circumſtances clearly ſhew, that if it were applied in much larger quantities, the effect would only be to promote the luxuriance of the crop in a higher degree. A gentleman of his acquaintance, in whoſe veracity he can confide, happening to be from home when a large field was limed, and having no occaſion for the whole quantity of lime that had been brought for that purpoſe, and laid down in one corner of the field, his ſervants, without driving it away, mixed what remained with the ſoil, although the lime lay there about four inches thick over the whole ſurface. The effect was, that for many years afterwards, the grain in that place was ſo immoderately luxuriant, that it fell over, and rotted before it came to the ear. After many years this luxuriance abated a little, ſo as to allow the grain to ripen; but it was there always much more luxuriant than in any other part of the field. An accidental experiment, nearly ſimilar to this, fell under his own obſervation. It happened that the ſervants of another farmer laid, by miſtake, a few heaps of lime upon a graſs field that he did not intend ſhould be broken up at the time. The miſtake was ſoon diſcovered, and no more lime was laid down at that place; and the few heaps (about a buſhel in each) were allowed to lie neglected, without being ſpread. The field was paſtured upon for ſeven or eight years after that, before it was converted into tillage; and the heaps were by that time become ſo flat, and ſo far ſunk into the ground, that they could hardly be diſcovered. Before it was ploughed up, the whole of the field was limed, and this part of it equally ſo with the reſt; nor were the old heaps touched till the plough went through them in tilling the field, when the lime was there turned up, with only a very ſmall mixture of ſoil. The conſequence was, that at every one of theſe heaps, a tuft of corn ſprung up with ſuch luxuriance as to be entirely rotted before harveſt; and for many years afterwards, theſe tufts could be diſtinguiſhed from the other part of the field at a very great diſtance, like ſo many buttons on a coat; and perhaps continue ſo to this day. From theſe experiments, as well as other conſiderations, there ſeems to be reaſon to conclude, that on ſoils which do not naturally abound with chalk, or other calcareous matter, there is leſs danger in giving too much lime than in applying too little, except in thoſe caſes where an over luxuriance is to be apprehended previouſly to ſuch limings.

It has been ſtated by a late agricultural writer, that in the counties of Lanark and Weſtmoreland, from one hundred to five hundred buſhels of lime-ſhells, after being reduced to powder, are applied to the Engliſh ſtatute acre; and that the buſhel of lime-ſhells, or calcined lime-ſtone, generally yields from two and a half to three buſhels of powdered lime; the price of which at the kilns varies from fourpence to ſixpence; the general average over the kingdom being rated at fourpence halfpenny the buſhel. In the county of Nottingham, the ordinary quantity does not exceed ſeventy or eighty buſhels. In the counties of Cumberland in England, and Weſt Lothian, Fife, Perth, Angus, Mearns, &c. in Scotland, from one hundred to one hundred and fifty buſhels is the uſual quantity; and this laſt may be ſtated as the general average quantity commonly uſed in all the other parts of the iſland.

It is aſſerted to have been often heard urged as an objection to the uſe of lime as a manure, that although it does indeed promote the fertility of a ſoil in a higher degree at firſt, yet, in the end, it renders it much more ſterile than formerly; on which account, they ſay, it ought not to be at all employed. This, like many other objections to uſeful practices, takes its riſe entirely from the avarice and unſkilfulneſs of thoſe who complain. It is chiefly heard of in thoſe parts of the country where it is not common for a farmer, after once liming a poor ſoil, to take fifteen or ſixteen crops of oats ſucceſſively, without any other dreſſing or alteration of crops. It muſt be a good manure that enables theſe ſoils to produce ſuch a number of ſucceſſive ſcourging crops of any ſort: but it would be a marvellous one indeed, if it ſhould prevent thoſe fields being exhauſted by them. But is it not well known, that in all the richeſt and beſt improved parts of the country, lime has been long employed as a manure? Yet, ſo far are thoſe ſoils from being rendered ſterile by it, that it is doubtful if any art, without the aſſiſtance of lime, or ſome calcareous matter, could ever have brought theſe fields to their preſent degree of fertility. Thoſe, therefore, who complain of the hurtful effects of lime as a manure, proclaim what they ought to conceal; that they have had in their poſſeſſion a treaſure, which might have enriched their poſterity, but which in their own life-time they have idly ſquandered away.

We are, however, not only unacquainted with the mode in which the lime operates upon the ſoil, but we are even in a great meaſure ignorant of the actual changes that are produced upon the earth after this manure is applied. It is often aſked, How long the effects of lime may be perceived on the ſoil? And, if by this queſtion it be meant to aſcertain the length of time that the effects of lime will be perceptible in promoting the luxuriance of the crop after one manuring, it is no wonder that very different anſwers ſhould be given, as the effects muſt vary with the quantity or quality of the lime employed, the nature of the crops that follow, and many other circumſtances, which it would be impoſſible to enumerate. But if it be viewed in another light; if lime be ſuppoſed to alter the ſoil, ſo as to render it ſuſceptible of being affected by other manures in a more ſenſible degree, ſo as to make it capable of producing crops that no art could otherwiſe have effected, and to admit of being improved by modes of culture that would not otherwiſe have produced any ſenſible benefit, the anſwer to the queſtion would be more eaſy, as in this light, it is pretty plain that its effects will be felt, perhaps, as long as the ſoil exiſts. It is believed farmers are ſeldom accuſtomed to conſider lime, or other calcareous manures, in this point of view; although, when it comes to be inquired into, it is not doubted but this will be found to be by far the moſt valuable effect of theſe meaſures. A few facts will beſt illuſtrate the meaning. In Derbyſhire the farmers have found, that by ſpreading lime in conſiderable quantities upon the ſurface of their heathy moors, after a few years the heath diſappears, and the whole ſurface becomes covered with a fine pile of graſs, conſiſting of white clover, and the other valuable ſorts of paſture graſſes. This ſhews that lime renders the ſoil unfriendly to the growth of heath, and friendly to that of clover. It is found by experience, that in all porous ſoils which are not expoſed to too much dampneſs, in every part of Scotland where lime has not been employed, heath has a natural and almoſt irreſiſtible propenſity to eſtabliſh itſelf. In thoſe parts of the country where lime has been much uſed as a manure, we find that the fields may be allowed to remain long in graſs, without becoming covered with that noxious plant. Again, it is well known by thoſe who have been attentive, and have had opportunities of obſerving the fact, that peas of any ſort can never be ſucceſsfully cultivated in any part of the country where the ſoil is not of a very ſtrong clayey nature, or where lime or other calcareous manures have never been employed. If the ground be made as rich as poſſible with common dung, although the peas in that caſe will vegetate, and grow for ſome time with vigour; yet, before they begin to ripen, they become blighted, uſually die away entirely before the pod is formed, and but rarely produce a few half-formed peas. But if the ground has ever been limed, although, perhaps, at the diſtance of thouſands of years before that period, it never loſes its power of producing good crops of peas, if it is put in a proper tilth for carrying them at the time. Again, in countries that have never been limed, the kinds of graſs that ſpontaneouſly appear, if left to themſelves, are the ſmall bent-graſs and feather-graſs. In places where lime has ever been uſed, the ground, if exhauſted, produces fewer plants of theſe graſſes; but in their ſtead white clover, the poa and feſcue graſſes, chiefly abound. The ſoil in either of theſe caſes may become equally poor; that is, may produce equally ſcanty crops: but the means of recovering them will be ſomewhat different. In the laſt caſe, a fallow ſeldom fails to prove beneficial. In the firſt, it is often of no effect, ſometimes even hurtful. In the laſt, a moderate dreſſing of dung produces a much more ſenſible and laſting effect than in the other. In the laſt the quality of the graſs, as well as its quantity, rather improves by age. In the firſt theſe circumſtances are reverſed. Several other obſervations might be made, tending to ſhew that ground, which has been once impregnated with calcareous matter, acquires qualities from that moment which it did not poſſeſs before, which it ever afterwards retains, and never returns exactly to its former ſtate. In addition to this it is obſerved, that although lime has ſuch powerful effects on the ſoil, it does not ſeem ever to incorporate with the mould, ſo as to form one homogeneous maſs; but the lime remains always in detached particles, which are larger or ſmaller in proportion as it has been more or leſs perfectly divided when it was ſpread, or broken down by the ſubſequent mechanical operations the ſoil may have been made to undergo. Hence it happens, that in ploughing, if there chance to be any lumps of calcareous matter in a dry ſtate upon the ſurface, they naturally tumble into the bottom of the open furrow as ſoon as the earth is edged up upon the mould-board, ſo as to fall into the loweſt place that has been made by the plough before the furrow-ſlice is fairly turned over. In conſequence of this circumſtance, it muſt often happen that, in the courſe of many repeated ploughings, more of the lime will be accumulated at the bottom of the ſoil than in any other part of it; and as the plough ſometimes goes a little deeper than ordinary, the lime that on theſe occaſions chances to be depoſited in the bottom of theſe furrows, will be below the ordinary ſtaple of the ſoil, it will be uſeleſs for the purpoſes of the farmer. It is commonly thought that the lime has ſunk through the ſoil by its own gravity, although it is certain that lime is ſpecifically lighter than any ſoil, and can only be accumulated at the bottom of the mould by the means above deſcribed: others think that the lime is chemically diſſolved, and afterwards depoſited there; but this idea is not corroborated by the facts that have been already brought to notice. The following directions are applicable in either caſe. To obviate this inconvenience, it behoves the farmer, in the firſt place, to be extremely attentive to have his lime divided into as ſmall particles as poſſible at the time of ſpreading; for, if theſe are ſufficiently ſmall, they incorporate ſo intimately with the mould, as to be incapable of being eaſily detached from it. On this account, as well as others, it is always moſt adviſable to ſpread the lime when in its dry powdery ſtate, immediately after ſlaking, before it has had time to run into lumps. It is alſo of importance to plough the ſoil with a more ſhallow furrow than uſual when lime is put upon it, eſpecially the firſt time it is ploughed after the lime has been ſpread upon its ſurface; becauſe, at that ploughing, the lime being all on the ſurface, a larger proportion of it is turned into the bottom of the laſt made furrow than at any ſucceeding ploughing; and therefore more of it will be buried beneath the ſtaple than at any other time, if the furrow ſhall have been very deep. This circumſtance becomes more eſſentially neceſſary in ploughing graſs-ground that has been newly limed; becauſe, in this caſe, the lime is leſs capable of being mixed with any part of the ſoil than in any other. It alſo becomes extremely neceſſary, in all ſucceeding times, to guard as much as poſſible againſt ploughing to unequal depths. See Anderſon's Eſſays.

In the work on the preſent ſtate of huſbandry in Great Britain, it is ſuggeſted as probable, that the propriety or impropriety of repeated limings depend more on the nature of the ſoil, and the modes of management afterwards adopted, than on any other circumſtance connected with it; and that, as in ſome diſtricts it is repeated two or three times in the courſe of twenty years, while in others a repetition of liming, except in mixture with other ſubſtances, is found injurious, it is impoſſible to account for ſuch variations in the practice or its effects on the ſoil, without obſerving, in the firſt place, that although there has been as yet no general rule eſtabliſhed, by which a farmer can determine what quantity of lime is beſt ſuited to a particular ſoil, yet in practice, a greater quantity is laid on ſtrong, denſe, ſtubborn ſoils, than on thoſe of a more friable nature. In the ſecond place, that the diverſity of meaſures by which lime is ſold at the different kilns, is often ſo great, as to leave it doubtful whether a farmer in one part of the iſland, who applies three chaldrons to the acre, does not uſe leſs than he who, in another diſtrict, applies two. And in the third place, that the quality of lime-ſhells is ſo extremely different, that in ſome caſes the farmer who lays five chaldrons on the acre, does not apply a greater quantity of effective manure than another who limes an acre with three only. And from various circumſtances which have been already noticed, in ſpeaking of calcareous earth, as well as from the great and general advantage of this ſubſtance on all ſoils and ſituations, except ſuch as are previouſly replete with calcareous matter, or too moiſt, the writer of the "Philoſophy of Agriculture" conceives, that its effects can only be underſtood from the idea of its actually ſupplying the nutrition of vegetables. This is ſtill further confirmed, by its contributing ſo much to the amelioration of the crops, as well as to their increaſe in quantity, as noticed by millers and bakers. If it be applied in a large quantity, it likewiſe kills animals in the ſoils, and alſo ſmall vegetables, and from the deſtroyed and decayed animals and vegetables, the ſoil is rendered more fertile, by being impregnated with mucilage. The ſuperabundant lime is uſeful as it becomes mild calcareous earth, by attracting carbonic acid from the atmoſphere, and afterwards gradually affording it to plants. By the fermentation it brings on, and the fineneſs of its particles, the texture of the earth is opened and divided.

It is evident that light ſandy lands, containing only a ſmall portion of vegetable matter, ſhould not be overdone with lime, unleſs we can aſſiſt them liberally with animal manures. Its great excellence on a ſandy ſoil is its mechanically binding the looſe particles, and preventing the different parts of the manure from eſcaping out of the reach of the crop. On clay, by means of the gentle fermentation which lime produces, the ſtubborn ſoil is opened; the manure readily comes into contact with every part of it, and the fibres of the plants have full liberty to ſpread. It is often ſaid that lime anſwers better upon ſand than clay; but let the farmer treble the quantity, and he will be convinced that lime is better for clay than ſand. Clay well limed becomes a marle, falling in water, and fermenting with acids: the air, rain, and dews are freely admitted, and the ſoil retains the nouriſhment of each. In conſequence of a fermentation raiſed in the ſoil, the fixed air is ſet at liberty, which in a wonderful manner promotes vegetation. It is the nature of lime, in its active ſtate, to diſſolve vegetable bodies. Upon this principle we may account for the wonderful effects it produces in the improvement of black moor-land, which conſiſts of diſſolved and half diſſolved vegetable ſubſtances. And it may be obſerved in general, that the greateſt quantity ſhould be uſed upon the deepeſt and richeſt ſoils, and the leaſt upon thoſe that are thin and light. On ſtrong clays and deep loams there is a ſubſtantial body for it to operate upon; conſequently, a conſiderable quantity will be required to pervade and give due activity to the whole; but as the ſoil is lighter, the quantity muſt be leſs, and the after-management in regard to crops extremely cautious. In liming a ſingle field, an attention to the quantity will often be found neceſſary: the ſoil of the higher parts being for the moſt part light and free, and that of the lower more deep and compact, where the ground is unequal. On ſome ſoils, particularly where the bottom is chalk, lime-ſtone, or marle, lime will be pernicious, eſpecially if the ſoil be thin.

Whatever be the method in which lime produces its beneficial effects upon land, it ſhould always be reduced into as fine a powder as poſſible, and ſpread out with the greateſt equality upon the ſoil, as by theſe means it will be more equally blended with it, and be more extenſively uſeful in promoting the growth of crops.

Conſidering lime as a ſubſtance operating upon the living ſubſtances in the ſoil, as well as mechanically upon the ſoil itſelf, we perceive the neceſſity of applying a ſufficient quantity at once, in order to produce theſe effects: for, if the quantity employed be ſmall, and the ſoil deep, its effects will be ſcarcely perceived. Many farmers imagine that lime will not anſwer upon their lands, becauſe they have laid it on in ſmall quantities, whereas in all probability they would have found a larger doſe highly beneficial. On clay, four or five hundred buſhels are laid on for wheat, but it can ſcarcely be expected to anſwer the expence. On moſs, bog, moor, &c. to be reclaimed from a ſtate of nature, the more is laid on the better it is. The beneficial effect of lime on ſandy land may be explained from its binding quality. But when ſuch lands are firſt broken up from their ſtate of heath, the vegetable matter is acted upon and reduced to manure by the corroſive power of the lime. On ſuch lands, the firſt crop of rye has more than paid the expences. By attracting water, lime has a tendency to lay land dry. By inſinuating itſelf between the particles of clay, it deſtroys their adheſions, breaks the ſtiffneſs of the ſoil, and gives readier acceſs to the operation of manures, and to the extenſion of the growing roots of plants. By attracting carbonic acid, or fixed air and water, and by its corroſive properties, it deſtroys the texture of bodies, and reduces vegetable matter to a ſtate of manure. It unites ſtrongly with oils, and renders them miſcible with water. By being deſtructive to inſects and vermin, it may alſo contribute to preſerve the ſpringing corn from their ravages.

Dr. Anderſon, however, ſuggeſts, that, from writers on agriculture having long been in the cuſtom of dividing manures into two claſſes, *viz.* enriching manures, or thoſe that tended directly to render the ſoil more prolific, however ſterile it may be, among the foremoſt of which was reckoned dung; and exciting manures, or thoſe that were ſuppoſed to have a tendency to render the ſoil more prolific, merely by acting upon thoſe enriching manures that had been formerly in the ſoil, and giving them a new ſtimulus, ſo as to enable them to operate anew upon that ſoil which they had formerly fertilized: in which claſs of ſtimulating manures lime was always allowed to hold the foremoſt rank; it would follow, that lime could only be of uſe as a manure when applied to rich ſoils; and, when applied to poor ſoils, would produce hardly any, or even perhaps hurtful effects. He acknowledges that he was ſo far impoſed upon by the beauty of this theory, as to be hurried along with the general current of mankind, in the firm perſuaſion of the truth of the obſervation, and for many years did not ſufficiently advert to thoſe facts that were daily occurring to contradict it. He is now, however, firmly convinced, from repeated obſervations, that lime and other calcareous manures produce a much greater proportional improvement upon poor ſoils than on ſuch as are richer; and that lime alone, upon a poor ſoil, will, in many caſes, produce a much greater and more laſting degree of fertility than dung alone. In direct contradiction to the theory it is added, that he never yet met with a poor ſoil in its natural ſtate, which was not benefited in a very great degree by calcareous matters, when adminiſtered in proper quantities. But he has met with ſeveral rich ſoils that were fully impregnated with dung, and therefore exactly in that ſtate in which the theory ſuppoſes that lime would produce the greateſt effect,—but upon which lime, applied in any quantities, produced not the ſmalleſt ſenſible effect.

The author of Phytologia ſuggeſts the idea of its ſupplying actual nutrition to vegetables, which ſeems probable, as it contributes ſo much to the melioration of the crops, as well as to their increaſe in quantity—wheat from land well limed being believed by farmers, millers, and bakers, to be, as they ſuppoſe, thinner ſkinned: that is, to turn out more and better flour; which it is ſuppoſed is owing to its containing more ſtarch and leſs mucilage. Hence is perceived another very important uſe of lime in the cultivation of land, which may be owing to its forwarding the converſion of mucilage into ſtarch, that is, to its forwarding the ripening of the ſeed, which is a matter of great conſequence in this climate of ſhort and cold ſummers. Mr. Young, from various minutes made in his Eaſtern Tour, concludes, that lime agrees with almoſt all ſoils; that it fails, however, on a thin loam or lime-ſtone; that it ſeems inefficacious on old paſture; that it has a ſtrong effect in killing weeds; but that the greateſt effect is on heath and moor-lands; where, as in the peak of Derbyſhire, it converts waſte ſoils into fine paſtures, without tillage: but the ſort is a ſtrong ſtone lime, burning ſoft and ſoapy, and the quantity laid on is very great, riſing to three hundred and ſixty or even one thouſand buſhels. There is great reaſon to attribute much of the benefit to quantity: in waſtes eſpecially, too much can hardly be laid on, becauſe diſſolving the roots of heath and other ſpontaneous growth requires a powerful agent. Of their ſtrong lime three hundred and ſixty buſhels are probably equal to five or ſix hundred buſhels of chalk lime. What then are five or ſix quarters, which is no uncommon quantity, laid upon an acre?

And the mode of uſing lime, in improving their heaths or moors, is firſt to pare the ground in the beginning of March, about an inch and a half thick, to turn it about in dry weather, when dry to gather it into heaps, and burn it into aſhes, to ſpread them even over the ground, to ſet on their lime, to ſpread and harrow it altogether, to plough the ground very thin, and to ſow it with turnips or rape; then the ſpring following to ſow with oats or barley, and good graſs ſeeds: another good dreſſing with lime after the firſt crops of ſeeds is got; and then it may lie for paſture. Spreading the lime in a ſlaked ſtate is by far the beſt method. The ſummer months are preferred, becauſe fewer coals are neceſſary for burning; in other reſpects, the winter months are juſt as good for laying the lime upon the ground, provided it be done in dry weather.

But in its application upon fallows it is found to produce the beſt effects when laid on early in the ſeaſon, and well incorporated with the ſoil while it is dry and powdery.

And the aſſiſtance of this manure has been highly uſeful in the cultivation of turnips; whole diſtricts, formerly uſeleſs, having been made to produce not only good crops of them, but alſo valuable ones of corn and broad clover. Its greateſt utility would ſeem to be upon light ſoils for theſe crops; as, where lime is the principal manure, they ſeldom ſow turnips, clovers, peas or beans, except upon lands that have been previouſly limed. Inſtances of this ſort are often met with upon the uplands; where, if any of the broad-leaved crops are ſown, where a part has been limed, and a part not, the parts where the lime has been laid will produce, it is ſaid, a valuable return, while that which has been dunged only will hardly repay the expence of ſeed and labour. The methods of uſing lime upon turnip-lands are various. Some farmers lay it on only before the laſt ploughing, and plough it in without harrowing: they alſo lay it in heaps, hot from the kiln, without being ſlaked. But probably the ſooner it is laid upon the land, and the more perfectly it is mixed and incorporated with the ſoil before the ſeed is ſown, the more certain and extenſive will its effects be found.

But the application of this ſubſtance upon clover-ley for oats is a mode of practice which ought not to be attempted. It is generally laid on in this way in the autumn, and ploughed down in the ſpring, but the crops ſeldom repay the expence.

This ſubſtance is alſo uſed as a top-dreſſing in ſpring upon graſs, or wheat and other grain; but upon the latter it is ſaid to be dangerous, unleſs the lime be made into a compoſt with dung or earth; in this form it will not only be ſafe but highly uſeful, except upon coarſe meadows abounding with ruſhes, and other trumpery, which it deſtroys by abſorbing the ſuperabundant moiſture which ſupports them.

But upon light ſoils, if ſeveral white crops be taken in ſucceſſion after liming, the land will be worn out; a white and green crop ſhould be taken alternately. Upon clay lands a ſummer fallow is ſometimes indiſpenſable; in that caſe the lime ſhould be laid on in July or Auguſt, and completely harrowed in before ploughing: two or three ploughings at leaſt are required to incorporate it well with the ſoil, and a ſuitable harrowing after each ſhould likewiſe be given.

However, about Perth in Scotland, according to the Report of that county, the quantity laid on ſtiff land, by ſkilful improvers in the low country, is from forty to fifty bolls to the acre; on light land, with a gravelly ſubſoil, thirty or thirty-five bolls are accounted a ſufficient doſe. In ſome parts of the carſe or clay land, which is not eaſily ſtimulated, they lay on eighty or ninety bolls. It is ſometimes laid on fallows, immediately before the ſeed furrow; on barley and graſs ſeeds, either before or after the barley is ſown; and in ſome caſes with the preceding crop, where turnips are cultivated, to prepare the ground for barley. Lime is in ſome inſtances mixed in compoſt dung-hills, in others it is ſpread on the green ſward, before the land be broken up from graſs. One infallible maxim with regard to lime is, that the longer it is kept near the ſurface, at leaſt within reach of the plough, until it be intimately mixed with the ſoil, and its virtues imbibed, ſo much the better. The firſt liming of land has always a more powerful effect than it has at a future but no diſtant period, the quantity being equal. Quick lime intended for wheat, after a fallow, or for barley and graſs ſeeds, might be ploughed in with a very ſhallow furrow, before the ſeed is ſown: for oats after ley, it ought to be laid on during the preceding autumn; and for paſture or a top-dreſſing, early in the ſpring or autumn, rather than in ſummer or in winter; becauſe, if the ſummer be dry, the graſs is burnt up by the lime, and in winter its virtues are leſſened by the froſt, nor does it ſo powerfully attract the influence of the air. It is common, but perhaps difficult to be accounted for, when lime is ſpread on ſhort heath or other barren ground, which has a dry bottom, to ſee white clover and daiſies riſing ſpontaneouſly and plentifully, the ſecond or third ſpring afterwards, where not a veſtige of either, nor even a blade of graſs, could be diſcovered before it was applied. Dr. Darwin remarks that he has been informed, that if a ſpadeful of lime be thrown on a tuſſock, which horſes or cattle have refuſed to eat for years, they will for many ſucceeding ſeaſons eat it quite cloſe to the ground; which is owing, he ſuſpects, to the graſs containing more ſugar in its joints, or to the leſs acidity of all its juices.

Where lime is to lie in a heap for any length of time, it ſhould be covered with earth, to preſerve it from the air and rain. It has been obſerved, that the benefit of lime is not apparent in a dry ſummer, and that it does not act fully as a manure, till it has been thoroughly ſlaked in the ſoil, by continued rains. In Eſſex an excellent practice prevails, of forming a compoſt of lime, turf, and ditch earth, at the gate of every field, ready to be applied as a manure when wanted. Twenty buſhels of lime mixed with forty buſhels of ſand form an excellent top-dreſſing for an acre of wheat, if laid on early in the ſpring. But lime, as firſt noticed, is apt to ſubſide beyond the depth of the common furrow; deep ploughing in this caſe is the only remedy applicable. In ſome midland counties a fallow is ſeldom made without being dreſſed with lime, under an idea that it mellows the ſoil, and makes it work well, while in tillage; and ſweetens or improves the quality of the herbage when laid down to graſs. For this purpoſe it is fetched eighteen or twenty miles. And two ſorts of lime are in uſe in ſome diſtricts, as about Derby. The Breedon lime, burnt from a very hard ſtone, and of ſingular ſtrength as manure; and the common lime, burnt from common ſtones, and called Ticknall or Walſal lime. The load-heaps are generally watered as they are thrown down from the waggon; and always turned over to complete the falling more effectually. If a quantity of lime be fetched in autumn or early in winter, to be uſed in the ſpring, when team-labour is more valuable, it is thrown up into a regular roof-like heap or mound, and thatched as a ſtack; a ſmall trench being cut round the ſkirts to catch, with an outlet to convey away, rain water. Thus the heap is prevented from running to a mortar-like conſiſtence by the ſnows and rains of winter, and thereby rendered more uſeful as manure.

In the Rural Economy of the Midland Counties it is noticed, that a turnip fallow was manured with Breedon lime, in general five quarters to an acre; part had double that quantity, and part had none. The turnip crop received no obvious advantage, but its effects on the barley were evident. The part not limed was the worſe crop, nearly in the proportion of four to three. But the part limed with ten quarters to an acre was the beſt crop. Whence the common notion, that more than five quarters of Breedon lime to an acre is ruinous to crops, ſeems to be ill founded. And in the Economy of Norfolk, lime is ſaid to be in good repute, though not in general uſe as a manure; different opinions being entertained reſpecting the value of it. This difference of opinion will ever remain, while general concluſions are drawn from particular incidents. It is uſed by many judicious farmers, even after marle, with ſucceſs. Upon hot burning ſoils it is generally found of the greateſt efficacy, and is perhaps the moſt effectual cure of ſcalds or burning patches of land that has yet been diſcovered; from theſe and other circumſtances lime is there conſidered as a cold manure. The general method of applying lime is to let it fall in large heaps, and to ſpread it out of carts upon fallowed ground either for wheat or barley. The quantity ſet on is about three chaldrons an acre; the price 9*s*. or 10*s*. a chaldron. (Now much higher.) From experiments made on turnips, barley, and wheat, it appears that lime does not act as a manure until it has been thoroughly ſlaked in the ſoil; and it ſeems as if the rains of ſummer were neceſſary to promote its operation. But in ſome parts of Yorkſhire lime is uſed invariably on every ſpecies of ſoil; and in moſt caſes with great ſucceſs. On the higher and more dry lands its utility is evident. At Malton it is laid on the calcareous quarry ſoil with ſucceſs. Its uſe to the looſe ſandy ſoils is fully eſtabliſhed. The prevailing crop is wheat on fallow. It is alſo pretty generally ſet on for rape, turnips, or other crops, after ſod-burning, and ſpread among the aſhes. It is alſo ſometimes ſet on for barley. But its effect on the firſt crop, except of wheat or rape, is ſeldom perceptible.

But the benefit of lime to graſs is a matter of diſpute; it is even thought by ſome to be detrimental. It ſeems, however, to be a generally received idea, that lime laid on graſs is not thrown away; for, whenever the land is turned up again, its benefit to corn will have full effect. The methods of liming are various. The worſt is laying it in large heaps, and ſuffering it to run to a jelly before it is ſpread. Next to this, is ſetting it about the land in ſmall hillocks; for, although they are ſpread before they approach to a ſtate of mortar, yet this method is injudicious. Lime falling in the open air breaks into ſmall cubical maſſes, which being once buried in the ſoil, remains in it for ages, without being mixed intimately with it. Lime ought therefore to be ſpread in a ſtate of perfect powder. It is therefore the practice of judicious huſbandmen to ſet lime upon the land in load-heaps, and ſpread it over the ſoil out of carts, as ſoon as it is ſufficiently fallen. Or the load-heaps are turned over, not ſo much to finiſh the falling, as to gain an opportunity of burying the granulous ſurface of the heaps; by which means, the fragments are at leaſt leſſened, if not reduced to powder. In the moor-lands the heaps are interlayered and covered up with moiſt turf or peat-mould, which bringing on a rapid fall, the whole is ſet on fire, and the ſurface kept free from granules by a covering of dry aſhes. The heaps, therefore, whether great or ſmall, ſhould be covered up with ſoil, either of the field they are ſet in, or that of lanes or ditches carried to them for the purpoſe; and if a ſpeedy fall be required, water thrown over this covering. If lime be uſed on fallows for wheat, it is generally ſpread in July, harrowed in as faſt as it is ſpread, and ploughed under with a ſhallow furrow, as ſoon as convenient. The uſual quantity is three or four chaldrons to an acre.

And “much depends upon the mode of applying the lime to the ſoil after calcination, according to Dr. Anderſon. If it is ſpread as ſoon as it is ſlaked, while yet in a powdery ſtate, a very ſmall quantity may be made to cover the whole ſurface of the ground, and to touch an exceedingly great number of particles of earth; but if it is ſuffered to lie for ſome time after ſlaking, and to get ſo much moiſture as to make it run into clods, or cake into large lumps, it can never be again divided into ſuch ſmall parts; and, therefore, a much greater quantity is neceſſary to produce the ſame effect, than if it had been applied in its powdery ſtate. But if the ſoil is afterwards to be continued long in tillage (as theſe clods are annually broken ſmaller by the action of the plough and harrows), the lime muſt continue to exert its influence anew upon the ſoil for a great courſe of years; it will produce an effect nearly ſimilar to that which would be experienced by annually ſtrewing a ſmall quantity of powdered lime over the ſurface of the ſoil; but as the lime muſt, in the firſt caſe, be paid by the farmer altogether at the beginning, which only comes to be ſucceſſively demanded in the other caſe, this deſerves to be attended to, as it may become a conſideration of ſome importance where lime is dear, and money not very plentiful.”

And it is conſtantly an object worthy of attention to remove the ſhells as ſoon as poſſible after the lime is drawn from the kiln; for it is known from experiment, that a ton of lime expoſed twenty-two days to the air after calcination, is augmented in weight to thirty hundred weight, and ſome kinds of lime even to thirty-five; which is little leſs than double.

In order to underſtand the goodneſs of lime, it is remarked by the ſame writer, that the lime from pure limeſtone is always of a bright white, when perfectly calcined without a tendency to any colour. When it has any colour it proceeds from the ſand, or other uncalcareous matters in its compoſition. There are, however, ſome ſorts of ſand that are of ſuch a pure whiteneſs, as not to debaſe the colour of the lime in the ſmalleſt degree; but theſe are rare; and there are ſome matters that alter the colour of the lime a good deal, without debaſing its quality in any conſiderable degree; but theſe are ſtill more rare than the former. Hence it follows, that the beſt lime for the purpoſe of the farmer, is that which is lighteſt, ſofteſt to the touch, and whiteſt. Softneſs to the touch is not, however, it is conceived, an unequivocal proof of the purity of the lime. He has ſeen one kind of lime that contained a large proportion of an uncalcareous impalpable powder, that was as ſoft to the touch as the pureſt lime; but this was a ſingular exception to the rule that is very general. The more they deviate from either of theſe teſts of purity, the worſe they are for the purpoſes of agriculture. But if the lime-ſtone loſes much of its weight in calcination, and the lime-ſhells are extremely light; if the ſhells require a very large proportion of water to ſlake them fully; if it is long before they begin to fall; if the lime-ſtone is not apt to run (or be vitrified) in the operation of burning; if it falls entirely when it gets a ſufficient quantity of water, after it has been properly calcined; if it ſwells very much in ſlaking, and if the lime is light, fine to the touch, and of a pure white, it may be concluded that it is extremely good, and may be uſed in preference to any other lime that is inferior to it in any of theſe reſpects. Theſe rules are perfectly ſufficient to decide as to the comparative value of any two kinds of lime that may be oppoſed to one another, and may be relied upon as ſufficiently accurate for the ordinary purpoſes of the farmer.

There are other methods by which the qualities or goodneſs of lime may be aſcertained with exactneſs, but which are beſt performed by an expert chemiſt.

Proper Seaſon for uſing Lime.—In reſpect to the moſt proper time of uſing lime to lands, there ſeems ſome difference of opinion among farmers, as well as to the ſtate in which it ſhould be uſed; ſome ſuppoſing the beſt time to lay it on dry ſoils intended for turnips, is in autumn, while others think the beginning of ſummer, as May and June, better. Some, likewiſe, contend that it ſhould be applied before it has been ſlaked; while others think it may be employed when even in a ſtate of conſiderable moiſture. The writer of the Farmer's Calendar, after putting the queſtion, whether lime burnt in January ſhould be then uſed or kept till ſpring, obſerves, that "there are two motives for burning ſtone or chalk; one is, for the ſake of reducing the material to powder, for accuracy in ſpreading; the other is, for the application of a cauſtic body deſtructive of living vegetables. For the former purpoſe, the lime had better be kept; for the latter, it is uſually laid on in ſuch large quantities, that it is not very material at what ſeaſon it is ſpread, provided it be done freſh from the kiln. It will have a greater effect in ſpring and ſummer, but the ſuperiority is not ſuch as to induce delay from a time in which the teams have little to perform, to a ſeaſon in which there is much work for them." And he further ſtates, that "the grand effect of this manure is on uncultivated waſte land. On moors, mountains, bog, and boggy bottoms, the effect is very great, but the quantity applied is conſiderable. The more the better. In Derbyſhire, as far as 600 buſhels an acre have been uſed; or 20 one-horſe cart loads of 30 buſhels: ſuch a dreſſing, when the ſpace to be improved is large, demands the employment of regular teams to be kept continually at work. In ſuch undertakings, it is idle to be nice about the ſeaſon of applying the manure; convenience demands that the work ſhould go on at all ſeaſons, but in the counties where lime is moſt uſed, the common ſeaſon is ſummer, and on fallows."

And there cannot be any doubt but that it is the beſt practice to apply it either in the ſpring, ſummer, or early part of the autumn, and in a ſtate as little moiſt as poſſible, as, under ſuch circumſtances, it may not only be laid on with the greateſt convenience, but be ſpread out in the moſt even and regular manner, which is a point of conſiderable importance in this huſbandry, and be laid on with leſs injury from treading the land, than could otherwiſe be the caſe.

The above writer alſo ſtates, that "liming is, in many diſtricts, connected with paring and burning, and it is one of the beſt methods of applying this manure. From a peck to a buſhel, according to its plenty, is added to, and mixed with, every heap of aſhes, and they are then ſpread together. The effect generally is conſiderable, but proportioned to the ſoil. The greateſt effect of this manure is upon land that has been long in a ſtate of nature; and particularly upon all peat ſoils, moors, mountains, and bogs. But upon all on which it is known to have effect, it is well applied in the aſhes of paring and burning."

But though the application of this ſubſtance properly belongs to the occupiers of lands, it is neceſſary that the proprietors of them ſhould render it as eaſy and convenient as poſſible, "either by ſearching for raw materials, opening quarries, and erecting kilns upon the eſtates under their care, or by bringing, from a diſtance, materials, fuel, or lime itſelf, at the leaſt poſſible expence, through the means of improved roads, rail-ways, or water-carriage." And that the ſame principle holds good "with reſpect to marles, and other groſs ſubſtances, to be uſed in their raw ſtate; as the advantages ariſing therefrom will always, eventually, find their way into the rent-roll."

Doctor Anderſon thinks it may be neceſſary to obſerve, that when farmers employ a great deal of lime, it ſometimes happens that their horſes' feet are burnt by it; which is extremely troubleſome, and ſometimes proves even fatal to the poor animals: a method of preventing or remedying that inconvenience will, therefore, be of uſe. The beſt method of preventing any inconvenience of this ſort is to ſpread the lime, when in its powdery ſtate, upon the field as evenly as poſſible, and to allow it to lie in that ſtate ſome time before you begin to plough it. If the lime has been in fine powder, it will have become perfectly effete in a week or ſo; after which time it will be as little corroſive as any kind of common earth, ſo that the horſes may work among it with perfect ſafety. But if it has been ſuffered to run into clods before it was ſpread, theſe, if not broken ſmall, will be longer in abſorbing their air, and, of conſequence, will remain longer in an acrid ſtate, ſo that the ploughing may, in that caſe, be deferred for a week longer, nor will it be even then ſo perfectly ſafe as the other. But if it becomes neceſſary at any time to plough in the lime immediately after it is ſpread, take care, ſays he, to do it only when the ſoil is perfectly dry, and in leading your horſes to the plough, take care to prevent them from going through any wet place, ſo as to wet their hoofs or ankles; for lime acts not at all upon any dry ſubſtance; but when it is in its acrid cauſtic ſtate, it will corrode the hair and fleſh in a moment, if it has acceſs to water. As ſoon as the horſes are unyoked, keep their feet dry till you have got them carefully bruſhed, ſo as to wipe away all the dry powdery lime that may adhere to them; and if the leaſt ſhower ſhould fall, unyoke your horſes immediately, and take them off the field. With theſe precautions, they may work among lime for any length of time, without receiving any damage whatever.

However, in caſe of any accident, by which a horſe or man that is working among lime ſhould be ſcalded by it, it is always adviſable for every farmer who has work of that kind going forward, to keep a tub of very ſour milk, or whey, in ſome place ready to waſh the part affected well with, which will quickly deſtroy the poignancy of the lime, and prevent the miſchief that would otherwiſe ariſe from it. The ſourer the milk or whey is, the better it will be for this purpoſe; it ought, therefore, to be long kept. For want of this, vinegar may produce the ſame effect, or very ſtale urine will be of uſe; but the milk or whey is the cheapeſt and beſt remedy, and ought always to be in readineſs where lime huſbandry is going on to any extent.

LIME, in *Botany*. See LEMON.

LIME-*Ammoniacal*, a kind of phoſphorus, invented by Mr. Homberg, and made of ſal ammoniac and lime. See *Ammoniacal* PHOSPHORUS, and LIME, *ſupra*.

LIME, *Bird*. See BIRD-*lime*.

LIME, *Brook*. See BROOK-*lime*.

LIME, *Burning*, a term ſignifying the proceſs of converting lime-ſtone, chalk, marble, ſhells, and other calcareous ſubſtances into lime, by means of heat, in kilns properly conſtructed for the purpoſe. See KILN.

In theſe caſes, the calcination is effected by different ſorts of fuel, in different ſituations, but principally by foſſil-coal, peats, or woods; theſe being laid in layers, alternately with thoſe of the calcareous materials, in the kilns, and the proceſs of burning continued for any length of time, by repeated applications of fuel and calcareous matters at the top, and drawing out the lime from below occaſionally as it is burnt.

But mineral coal, or culm, are unqueſtionably the moſt convenient and ſuitable materials for effecting this buſineſs, where they can be procured in plenty, and at a ſufficiently cheap rate, as they burn the ſtone, or other calcareous matter more perfectly, and, of courſe, leave fewer cores in the calcined pieces than when other ſorts of fuel are employed for the purpoſe.

However, Mr. Dodgſon has had much ſucceſs in burning lime by the uſe of peats; as he ſtates, in the Farmer's Magazine, that he is "convinced, from experience, that lime-ſtone can be burnt to better purpoſe, and at leſs expence, with peat than with coal. When coal is uſed, the lime-ſtones are apt, from exceſſive heat, to run into a ſolid lump, which never happens with peat, as it keeps them in an open ſtate, and admits the air freely. The proceſs of burning, alſo, goes on more ſlowly with coal. No lime can be drawn for two or three days; whereas, with peat, it may be drawn within twelve hours after fire is put to the kiln; and in every ſucceeding day nearly double the quantity of what could be produced by the uſe of coal. The expence is comparatively ſmall. A man and a boy will dig as many peats in one day as will burn 60 Carliſle buſhels of lime, (the Carliſle buſhel is equal to three Wincheſter ones,) and the expence, including drying, will not exceed four, or, at moſt, five ſhillings; while the coal neceſſary for burning the ſame quantity of lime would have coſt twelve ſhillings at the pit. The wetneſs of ſeaſons is no argument againſt the uſe of peats, as they can be ſtacked near the kiln, when half dry, at any time of ſummer; the moiſture will be exhaled from them during winter, and they will be in a fit ſtate for burning in the months of April or May. He lives in the north-eaſtern diſtrict of Cumberland, where the farmers, in general, burn their own lime; and though there is coal in the immediate neighbourhood, he gives a decided preference to peat, for the reaſons above-mentioned." And it is well known, that this kind of fuel has been occaſionally uſed in many parts of the kingdom for the ſame purpoſe, from a very early period, without any complaint of the want of ſucceſs.

In the practice here ſtated, no particular form of kiln was found neceſſary, nor any particular ſort of management in the proceſs of calcination; the proportion of peat depending upon the nature of the lime-ſtone employed, and other circumſtances.

It has been conſidered by Mr. Marſhall, that "the manufacture of lime is an art of which the manager of an eſtate ought not to be ignorant." And he conceives, that "he ought to have, at leaſt, a ſufficient knowledge of its theory, to enable him, when occaſion requires, to ſuperintend or direct its practice. For it ſeldom anſwers, unleſs where materials are plentiful and fuel cheap, for every tenant upon an eſtate to manufacture his own lime. A full-ſized kiln accumulates a ſtronger heat, with a given proportion of fuel, than a ſmall one of the ſame form," which is without doubt a great ſaving.

It is ſuppoſed, that "the chief or ſole intention of burning lime-ſtone for manure, appears to be that of reducing it in the readieſt and cheapeſt manner to an impalpable powder. For experience ſufficiently ſhews, that quick-lime is injurious, rather than beneficial, to vegetation; and that burnt lime-ſtone does not operate as a manure until it has regained the fixed air, of which the fire deprived it. If it could be reduced by mechanic powers to powder of equal fineneſs, its effect, as manure, would doubtleſsly be the ſame as that of dead lime (effete). It is in the perfect ſolution which well-burnt lime-ſtone has received, by the expulſion of its fixed air in the fire, ſo as to have completely looſened its texture, and unbound its every atom, that we are to look for its prompt effect and the ſhortneſs of its duration, comparatively with unburnt calcareous ſubſtances. Hence the main point to be attended to is to expel the whole of the air. For, unleſs this be accompliſhed, the ſolution becomes imperfect; the ſtones, inſtead of completely diſſolving into impalpable atoms, break into granules, or flakes; leaving, perhaps, a firm core in the centre, to encumber, rather than to fertilize, the ſoil" on which they are applied. "There is, however, an oppoſite extreme to be avoided, and with greater care. For an unburnt ſtone may be returned to the kiln, but one which, by too intenſe a heat, is vitrified, or changed to a ſtate of impure glaſs, is not only rendered uſeleſs, but has incurred an extraordinary waſte of fuel. Conſequently, ſtones that are prone to vitrification ought to be broken down into ſmall pieces; otherwiſe, the fire is required to be ſo intenſe, that the ſurface becomes vitrified, before the air from the centre can be expelled." And "another ſuggeſtion, reſpecting the proper ſize of the ſtones to be burnt, may have its uſe. Where fuel is weak, or dear, the materials require to be broken into ſmaller fragments, than where a ſtrong fire can be kept up at a ſmall expence; while, under the latter circumſtance, and where the ſtone is not prone to vitrification, much of the labour and expence of breaking may be ſaved, by uſing an extra quantity of fuel, and keeping up a ſtrong fire in the kiln," or place where it is burned; the form or conſtruction of which depends partly on the qualities and value of the materials, and partly on the kinds of fuel that are made uſe of, and the differences of their prices at the places where they are employed. See KILN.

It is uſeful that the proceſs of burning lime ſhould go on during January and February, as well as moſt of the winter, and alſo in the ſummer months. Perpetual kilns are wrought in many diſtricts, eſpecially the northern ones, and in Ireland; the lime, when not taken away, being preſerved, in ſheds erected for the purpoſe, from the wet. The uſual mode of managing with them is, for the farmers to contract for ſome ſort of meaſure, according to the cuſtom or practice of the particular diſtrict; being careful that it is well burnt, and of a proper quality in other reſpects. The differences in the expence of burning will depend on the abundance or ſcarcity of fuel, and the convenience of the ſtone for carriage.

LIME, *Calx*, *Calx viva*, in the *Materia Medica*, &c. is prepared by breaking a pound of lime-ſtone into ſmall pieces, and heating it in a crucible in a very ſtrong fire for an hour, or until the carbonic acid is entirely driven off, ſo that on the addition of the acetic acid, no bubbles of gas ſhall be extricated. Lime may be made by the ſame proceſs from ſhells previouſly waſhed in boiling water, and cleared from extraneous matters. In the former pharmacopeias lime was ranked among the articles of the Materia Medica, and taken as prepared for its uſes in the arts; but in the laſt London Pharmacopeia particular directions are given for obtaining it in a purer ſtate. Two varieties of the carbonate are ſelected from which it may be prepared, *viz.* lime-ſtone and ſhells of oyſters; the latter of which contains the leaſt foreign admixture; but even the former, thus prepared, will be much purer than that which is uſually made from chalk. According to Kirwan, carbonate of lime conſiſts of 45 parts of carbonic acid and 55 of lime: but from whatever combination it be obtained, lime is always the ſame ſubſtance, poſſeſſing the ſame characters, and producing the ſame effects, though it may be different with regard to the proportion of heterogeneous matters with which it is mixed; and, therefore, the diſtinctions which were formerly made between its medical qualities, as obtained from different ſources, were ſuperfluous, and will not, in the preſent ſtate of ſcience, be likely to be renewed by the introduction of more than one. To the perfection of the lime it is neceſſary that the carbonic acid ſhould be entirely expelled; but in the preparation of ordinary lime this is done very imperfectly; for to all common purpoſes it is ſufficient if it be burnt ſo as to ſlake on the addition of water; on the other hand, it may alſo be noticed that where lime-ſtone is employed, the heat may be urged too far and be too long continued. The pure earths will not vitrify by heat, but many earthy admixtures readily will; and as moſt lime-ſtones contain ſome portion of other earths, they may, under theſe circumſtances, vitrify, and form a coating over the ſurface of the lumps, which will defend them from the action of water, and thus prevent their ſlaking or ſolution; ſo that lime may thus be over-burnt. The pieces of ſtone uſed for burning ſhould be as nearly as poſſible of equal ſize. If half its weight of water be poured upon lime, it ſwells and falls into a white powder, much heat is evolved, part of the water riſes in ſteam, and part combines with the lime; this is called ſlaked lime, and in this ſtate carbonic acid from the air eaſily attaches to it. When perfectly dry it may be kept in bottles for any length of time without alteration; but to obviate any chance of its being impure from the above cauſe, it is uſual to direct its being employed newly prepared. Lime newly ſlaked, and to which more water is added, ought not to effervеſce on the addition of an acid.

Lime is much uſed by tanners, ſkinners, &c. in the preparation of their leather; by ſoap-boilers for diſſolving the oil, and facilitating its union with the alkaline ſalt; and by ſugar-bakers for refining their ſugar.

It is alſo of ſome medicinal uſe; being applied externally in deſiccative and epulotic medicines.

It is uſed alſo as a depilatory; and has been ſometimes made into an unguent with honey for rheumatic and other obſtinate fixed pains of the joints or limbs: this unguent is much commended by Fuller, who obſerves, that it is almoſt cauſtic. As an abſorbent earth, it is anti-acid, and capable of abſorbing the acid matters which are produced in digeſtion from the weakneſs of the ſtomach, in diſeaſes proceeding from a ſpontaneous acid, ſo well deſcribed by Boerhaave. It is the fitter in theſe diſeaſes, which are commonly the effect of the inactivity and weakneſs of the fibres, as it poſſeſſes a tonic quality, which other abſorbent earths have not. Beſides, perſons afflicted with theſe diſeaſes are ſubject to much wind, which is, perhaps, nothing elſe but gas; and quick lime is very capable of abſorbing that fluid. As quick-lime is alſo drying, a little cauſtic, and conſequently cicatriſing, it may contribute to cure certain ulcers, eſpecially thoſe of the ſoft parts. Accordingly, ſeveral able phyſicians have preſcribed it ſucceſsfully for internal ſuppurations, and in the phthiſis pulmonalis. Moreover, the property which quick-lime has of attenuating viſcid matters, and of decompoſing ammoniacal ſalts, has been advantageouſly applied to diſſolve ſtones in the bladder and kidneys. But the beſt method of adminiſtering quick-lime internally has been thought to be by giving the lime-water; becauſe this water is ſuppoſed to poſſeſs all the medicinal virtues of quick-lime, and becauſe the earthy particles are thus reduced to the greateſt fineneſs, and are, conſequently ſuſceptible of the moſt perfect diſtribution. However, this ſhould be adminiſtered with great caution, and much diluted; and, after all, it is doubted, whether the lime-water, thus diluted, has all the medical qualities which might be expected from quick-lime. Macquer.

LIME, *Carbonat of*, a term applied to lime when ſlaked or in the ſtate of lime-ſtone: when thus ſaturated it is in the leaſt active condition. See LIME *ſtone*.

LIME, *Cream of*. See CREAM.

LIME *Effete*, that which has been ſlaked by the air and moiſture of the atmoſphere after long expoſure.

LIME-*Galls*, in *Natural Hiſtory*, a ſort of galls or vegetable protuberances, formed on the edges of the leaves of the lime-tree in ſpring time; they are very common in the plantations of limes, and are irregularly ſhaped, but uſually oblong and rugged, and of a reddiſh colour; they occupy only the edges of the leaves, and are of a red colour, ſometimes very beautiful. As theſe are very plentiful, M. Reaumur was of opinion, that they might be of ſervice in the dyeing trade; he made trial by rubbing them on ſome parts of his linen, and found that they gave a very beautiful red colour, which did not come out in the firſt waſhings afterwards. It is extremely probable, that there wants only inquiry to prove that we have many valuable productions of this kind, which, though diſregarded at preſent, might prove of great uſe in the ſeveral mechanical arts as well as in medicine.

Theſe galls of the lime-leaves are formed by a worm, which inhabits them during its term of life, being found in them of all ſizes, from the moſt minute to that of the full growth, which is about half an inch in length; but when its period of life, as a worm, draws near, it deſerts this habitation, and goes elſewhere to paſs into its chryſalis ſtate. See GALLS.

Lime *Huſbandry*, a term uſed to ſignify that ſort of management which relates to the application of lime on land. See Lime.

Lime-*Kiln*, a ſort of kiln, conſtructed for the purpoſe of burning lime. Kilns of this nature are formed in a variety of different ways to ſave expence, and anſwer to the particular nature of the fuel. See Kiln.

Lime, *Quick*, a term applied to lime in its moſt powerful or cauſtic ſtate, before it has been rendered mild by the abſorption of carbonic acid gas, or fixed air, from either the atmoſphere or the ſoil.

Lime-*ſtone*, in *Agriculture*, a kind of calcareous ſtone, which is capable of being converted into lime by means of calcination. It would ſeem from the remarks that have been already made, in ſpeaking of the nature of lime, that this ſort of ſtone exiſts in different ſtates of purity, and conſiſts of different ſorts of ſubſtances in different ſituations, from which much diverſity in its effects, when converted into lime, is produced; ſome ſorts being more proper for the purpoſes of agriculture, while others are better adapted to thoſe of building, &c. See Lime.

It may be worthy of remark, that all ſuch ſorts of lime-ſtone as contain impurities, ſuch as clay, ſand, or ſtony matter in their compoſitions, are more proper in general for the purpoſes of agriculture, than for thoſe of building. Where lime-ſtone is plentiful and fuel ſcarce, it might be employed for the purpoſe of huſbandry with great advantage in its uncalcined ſtate, after being pounded or ground into a fine powdery form, by means of mills or other machines. And it is ſtated in the Survey of the County of Perth, that in Rannoch, a diſtrict of that county very remote from coal, a machine was erected by the late commiſſioners of annexed eſtates for this purpoſe, which was driven by a ſtream of water. Mr. Stewart, of Croſmount, who ſaw the machine, the pounded lime-ſtone, and its effect on the land, favoured the author with the following remarks; "There were two pounders, and a third was afterwards added, all from Carron, at a ſmall expence. The pounded lime-ſtone was carried from the machine by a ſmall run of water to three different ponds, one above the other. The upper pond contained the groſſeſt particles, and the lower pond the ſmalleſt or fineſt parts of the lime-ſtone, which reſembled clay or marle from its ſmoothneſs." The middle pond contained that which, it would appear, Mr. Stewart thought to be properly pounded; becauſe he adds, "the run of water might have been ſtronger, which would have enabled the mill to double the quantity grinded, which would ſerve the purpoſe of manure equally well, if not better, than by being pounded ſo very ſmall. All that was pounded before the machine was carried off by a flood, or the moſt of it, was uſed by colonel Alexander Robertſon, uncle to the preſent colonel Robertſon of Struan, who had a farm in the neighbourhood of the mill. The effects of it were viſible upon the ground, which were ſhewn by the colonel to different gentlemen, and approved of." It ſeems, however, that before its virtues could be fully aſcertained by repeated and varied experiments, a torrent in the brook that drove the mill carried all the machinery away, or at leaſt deranged it ſo that it was never reſtored. There is, it is ſuppoſed, little doubt of its beneficial effects on land; or of its effects being more powerful, in one ſhape or other, than thoſe of the ſame quantity of calcined lime-ſtone, becauſe the virtues muſt be in proportion to the quantity of calcareous earth in each. Any given quantity of raw lime-ſtone loſes one-third of its weight when burnt into ſhells. Nothing is here diſſipated except the water; all the calcareous earth remains. It is alſo found, that any given quantity of ſhells produces double that quantity of powdered or ſlaked lime. Therefore, a quantity of raw lime-ſtone, a buſhel for inſtance, has double the quantity of calcareous earth which is in a buſhel of ſlaked lime; conſequently its influence as a manure muſt be double. What is commonly ſuppoſed, and the writer thinks with probability by thoſe who uſed both kinds, without making any accurate experiments, is that the effects of the raw lime-ſtone are ſlow, but more laſting; of the calcined lime, more immediate, but leſs durable.

And it has been ſtated in a periodical work, that "the difference between lime-ſtone, freſh from the rock, and that which has been calcined, conſiſts in the former poſſeſſing, as one of its principal component parts, a very conſiderable proportion of fixed air or carbonic acid, a principle of which it is entirely deprived in the burning, if the operation is properly conducted; a circumſtance well worth the attention of proprietors, as, in that ſtate, its beneficial effects conſiſt chiefly in the power it poſſeſſes of neutraliſing acids, or decompounding metallic oxyds; but upon the animal or vegetable ſubſtances it meets with in the ſoil, it can produce no alteration." For "many years ago, an attempt was made by lord Kames to uſe unburnt lime-ſtone as a manure; the ſucceſs of which, it is believed, has not been recorded; indeed, the trial would probably, it is ſuppoſed, prove abortive, if made upon moſs, or mooriſh lands, which, owing to the great quantity of vegetable matter they contain, cannot poſſibly be benefited by any ſubſtance poſſeſſing leſs activity than quick or cauſtic lime."

A machine for this uſe, that admits of being wrought by ſteam, wind, water, or the power of horſes, is repreſented in *Plate Agriculture*, in which *a* repreſents a beam, ſupported by four ſtrong poſts joined together by tranſverſe pieces of wood, as ſeen in the figure, and at the top ſufficiently ſeparated to allow the wheel to work: *b*, a wheel with a groove on the circumference, ſufficiently deep to receive the beam *a*, with a large iron ſpindle or axis, moveable in a buſh made of bell metal: *c*, a weight of a conical ſhape, of caſt iron; the baſe ſtudded with knobs or protuberances, about two inches long, of a diamond ſhape, terminating in a blunt point, and about five inches in circumference at the bottom: *e*, the face of the weight or pounder, which is hidden from view in the cut: *f*, a circular building ſunk below the ſurface of the ground; the bottom prepared by a ſtratum of clay, well tempered, and mixed with a proportion of burnt lime-ſtone, powdered without being ſlacked, and forge aſhes beat very ſmall. When this is properly dried, a bed of ſand, about 18 inches in thickneſs, is laid about it, and paved with common paving ſtones, of the kind uſed for ſtreets; which, after being well beaten down, is covered with another bed of ſand of the ſame thickneſs, which ſhould be paved in the ſame manner, and afterwards well beaten down. The foundation of the building ſhould be, at leaſt, ſix feet below the common ſurface; which allows 18 inches for the clay, 36 inches for the two beds of ſand, and 18 inches for the two courſes of pavement. And the "circumference ſhould conſiſt entirely of hewn ſtone, at leaſt the uppermoſt three feet of it; the ſtones of which ſhould be ſtrongly batted together with iron, and ſecured on the outſide with numerous wooden poſts drove into the earth, and different courſes of pavement, extending at leaſt ſix feet all round, carefully laid and well beaten down. A floor prepared in this manner, if it is not uſed too ſoon, will reſiſt any force that can be let fall upon it. The lime-ſtone laid into it ſhould not be too ſmall, and ſhould have a light bedding of ſand, in ſoil, to give it ſtability. The building may be of any ſize, according to the powers of the machinery, and the weight of the beater." Others have ſuggeſted, that the pounding of lime-ſtone may be greatly facilitated by a very ſimple contrivance; merely that of kindling a fire upon the ſurface of the rock, or round any quantity of the lime-ſtone after it is quarried, and expoſing the ſtone to the heat of it for ten or twelve hours. During the heating, a great deal of it flies to pieces, and the remainder very readily gives way to the ſtroke of the hammer. It is alſo ſuppoſed, that conſiderable advantage may be derived from a machine of this kind, in reducing burnt lime-ſtone to a powder, before it is ſlaked by the action of the air or moiſture, as, in that ſtate, its operation upon the ſubſtances it meets with in the ſoil is much more conſiderable than after it has abſorbed the fixed air; and when employed in building, it cements immediately, and may be uſed with ſuperior advantage in the conſtruction of aqueducts, harbours, and other ſituations expoſed much to water, and where haſty drying is of importance.

It may be noticed, that the expence of ſuch a machine will vary according to circumſtances, but it cannot be great, and in many places it may be added to threſhing and corn mills, and the expence be greatly leſſened in that way.

It is obvious, that the analyſis of lime-ſtone may be effected in the ſame way as thoſe of other calcareous materials, except that where the ſtone is of a hard and firm texture, it ſhould be reduced into a ſtate of powder, in order to expedite its ſolution. Where the lime-ſtone ſubjected to analyſis does not yield more than two-thirds of its weight of pure chalk, it can ſeldom be burnt with profit; unleſs in a county where fuel is cheap and lime is dear. Good lime-ſtone yields upwards of ninety *per cent.* That of particular quarries is almoſt wholly calcareous, as has been already ſeen.

LIME-*ſtone Gravel*, a hard ſort of calcareous marle, that aſſumes the appearance of ſmall ſtones or gravel, which, when ſpread upon the ground and mixed with it, gradually falls into ſmaller pieces, and fertilizes the ſoil in proportion as it breaks down and mixes with it. It is a ſort of manure little known in Britain, although it is common in many parts of Ireland.

But after what has been already obſerved, little need be ſaid as to the qualities or mode of applying this manure. The farmer will eaſily be able to perceive, that if the pieces of which this gravel conſiſts are large, and diſſolve but ſlowly, the quantity applied at one dreſſing ought to be great, and the effects will be ſlow and laſting; but if the gravel be ſmall, it will require a ſmaller quantity, which will operate more quickly, and laſt for a ſhorter time, like all other calcareous ſubſtances in the ſame circumſtances, or which are applied in the ſame manner to lands.

LIME-*ſtone*, in *Mineralogy*. See LIME.

LIME-*ſtone*, *Magneſian*. See DOLOMITE and RHOMB-SPAR.

LIME-*ſtone*, *Quartzy*. See KONIT.

LIME-*ſtone*, *Fetid*. See SWINE-*ſtone*.

LIME-*ſtone*, *Eccentric*. See ARRAGONITE.

LIME-*water*, *liquor calcis*, *aqua calcis*, *aqua calcis ſimplex*, in the *Materia Medica*, is prepared by pouring twelve pints of boiling diſtilled water on half a pound of lime, and ſtirring them together: let the veſſel be immediately covered, and left to ſtand for three hours; then keep the ſolution upon the remaining lime in ſtopped glaſs bottles, and pour off the clear liquor when it is wanted for uſe. Lime is ſoluble in about 450 times its weight of water, or little more than one grain in one fluid-ounce, forming a tranſparent ſolution; hence the proportion here directed, is in fact more than is required for the ſaturation of the water; but the larger quantity allows, moreover, for any impurity contained in the lime, and as it is a cheap article, the quantity uſed is ſcarcely of any importance. The proceſs here adopted is ſimple, efficacious, and convenient, and by keeping the ſolution ſtanding upon the lime it will always be ſaturated; and the place of any cruſt of carbonate of lime which forms upon the ſurface, if expoſed, will be ſupplied from the lime, which remains in a ſtate ready for ſolution. Lond. Pharm. 1809.

The general opinion of lime acting as a cauſtic, and conſuming the bodies it was made to act upon, by means of the great quantity of particles of fire it contained, long denied any preparation of it a place among internal medicines; at length, water poured upon it was found to take in a part of its virtues, and to be a valuable medicine, and very ſafely to be given internally in large quantities.

For this purpoſe, a gallon and a half, or two gallons of water, were poured by degrees upon a pound of freſh-burnt quick-lime; the veſſel ſhaken when the ebullition ceaſed, and then ſet by, till the undiſſolved lime had ſettled; after which, the liquor was poured off, and paſſed through a filtre. Only a ſmall portion of the lime is diſſolved by the water, and the remainder gives a ſtrong impregnation to large quantities of freſh water, though not ſo ſtrong as the firſt; great part remaining at laſt undiſſolved: this reſiduum, calcined again, becomes quick-lime, as before; and by repetitions of this proceſs, nearly the whole may be diſſolved. The ſolution has a ſtrong ſtyptic taſte; and its effects in chemical mixtures are ſimilar to thoſe produced by quick-lime. In veſſels quite filled with lime-water, and exactly cloſed, it may be kept unchanged for many months; but in open veſſels, the calcareous matter ſoon ſeparates from the aqueous fluid, and forms a cruſt or cream upon the ſurface, inſipid and indiſſoluble as the earth in its natural ſtate, and again convertible into quick-lime by repeated calcination. It is obſerved, that the quantity of calcareous matter that is thus ſeparated from lime-water, is even greater than it ought to be, if it was exactly proportioned to the evaporation of the water; the cauſe of which is, that the quick-lime gradually recovers from the air as much gas as is neceſſary to deprive it of its properties of quick-lime, and to reſtore it to its ſtate of ſimple calcareous earth, mild, effervеſcing, and unſoluble in water. Hence lime-water by long expoſure to air, loſes much of its ſtrength, and at laſt becomes almoſt inſipid. It is neceſſary alſo, when this liquor is employed as a menſtruum, to add ſome quick-lime in ſubſtance, in order to continue the impregnation of the water with the lime.

All lime is not equally good for the making of this water; but the ſeveral kinds differ, according to the ſubſtances they are made from. In Holland they make lime of ſea-ſhells, which they find in vaſt abundance on their ſea-ſhores. This was alſo a practice in the time of Dioſcorides; but the lime thus made, it has been ſaid, is not fit for making lime-water. The water made from it does not keep long, and is leſs ſtyptic, and ſweetiſh to the taſte, and is greatly inferior to the water made with lime burnt from ſtones. The newer the lime is, the leſs it has been expoſed to the air, and the drier it has been kept, and finally, the more it has held together without crumbling, or mouldering to powder, the better it is for making lime-water. Mem. Acad. Par. 1700.

It appears now, from the ingenious Dr. Alſton's experiments, that one part of quick-lime is ſufficient for five or ſix hundred parts of water. Water will diſſolve but a certain portion of quick-lime; and how much that is cannot be eaſily aſcertained. So far ſeems certain from Dr. Alſton's experiments, that one pound of quick-lime is ſufficient for making ſix hundred pounds of good lime-water; and that thoſe who with Charas have ſuppoſed, that the ſecond and third lime-water is weaker than the firſt, have been led into an error by the ſmall quantity of water they uſed. And it has been generally believed, that in order to obtain good lime-water, the quick-lime muſt not only be recent and fully calcined, but alſo for one part of quick-lime only eight, ten, or, at moſt, twelve parts of water taken; as if it could impregnate no more. But the doctor ſays he has found, by many experiments, that it is altogether indifferent whether the water be hot or cold, poured on gradually, or at once, the water poured on the lime, or the lime thrown into the water; whether the quick-lime be in ſhells or ſlaked; or even expoſed to the air for ſeveral months, for ſuch quantities of the water as are commonly uſed; and if the quick-lime be freſh, whether for one pound of it, eight, ten, twenty, fifty, or five hundred pounds of water be taken. Only it is neceſſary, even for the firſt water after the ebullition is over, to ſtir and mix the lime with the water, and allow it time to impregnate itſelf; which is beſt known by the cruſt formed on its ſurface. Filtration indeed is not neceſſary, if it be not to prevent any undiſſolved lime being mixed with it; or cruſts diminiſhing its tranſparency.

The doctor, for his own uſe, poured about eight pounds of boiling water upon a pound of ſtone quick-lime in a glazed earthen veſſel. He drank about a pint and a half of this lime-water daily for about ſixteen months; filling up the veſſel, when neceſſary, with freſh water, ſometimes hot and ſometimes cold, without obſerving any difference in the lime-water, which he conſtantly filtered through grey paper before he drank it. He obſerved, that the lime was not exhauſted after two years and two months, nor was the water ſenſibly weaker, when it ſtood a ſufficient time on the lime, which he knew by the cruſts that were formed. But the lime becoming conſiderably lighter, after it is long thus uſed, it at length requires ſeveral days to ſubſide, and form the cruſts, and after the cruſts are formed, it does not leave half the water clear as it did at firſt. On the whole, this ſingle pound of lime afforded the doctor about ſix hundred pounds of lime-water. He adds, that having taken lime-water made indifferently of lime-ſtone, or of chalk, or of ſhells, and ſometimes made of all the three together, he was never able to diſcover any difference in their effects. But ſo much lime-water is not to be obtained from quick-lime, unleſs it be freſh, completely calcined, and free from heterogeneous ſubſtances; for if defective in any of theſe, it will yield proportionably leſs lime-water. Lewis's Mat. Med. and Macquer's Chem. Dict.

Mr. Burlet has given an ample account of its effects in the French Memoirs, chiefly from his own experience. But he obſerves, it ſucceeded much better in Holland, &c. than in France. It is a powerful alterant, and, like a pure alkaline water, fitted to blunt and deſtroy acid ferments, which are the principles of all obſtructions, and the cauſe of moſt chronic diſeaſes. Its principal uſe is in cachexies, green-ſickneſs, dropſy, ſcurvy, obſtructions on the liver, ſpleen, &c.

Experience has ſhewn lime-water to be an excellent medicine in many caſes; in the gravel and ſtone particularly. And it has alſo been found very ſerviceable in the gout, in habitual relaxations of the bowels, and in other caſes of relaxation. In ſome kinds of the ſcurvy likewiſe it is of uſe; and is often applied with ſucceſs externally to ulcers, &c.

Fabricius ab Aquapendente aſſures us, he cured a ſcirrhous ſpleen, and the dropſy, by a continued uſe of ſponges dipped in common lime-water, and placed near the part affected. Boyle's Works, Abr. vol. i. p. 80.

Lime-water, which was long looked on as a cauſtic, was, in the laſt century, found to be a very ſafe and valuable remedy. It is uncertain who firſt ventured to give it inwardly, but Willis, Bates, and Moreton, ſeem to have uſed it much.

Lime-water kills worms, and many other, if not all, inſects. Hence Dr. Alſton concludes, it might prove a good anthelmintic for children; and experience has confirmed this notion.

It is probable, that lime-water may be of great uſe in long ſea-voyages, preventing the corruption of water, or inſects breeding in it, as well as curing the diſeaſes to which ſea-faring people are moſt ſubject. The experiment is certainly ſafe, eaſy, and attended with no expence; one pound of freſh well-burnt quick-lime of any kind being enough for a hogſhead of water, which may not only be uſed for common drink by the diſeaſed, or for prevention by the healthy; but alſo by boiling and expoſing it to the air for a ſhort time, it may be reduced to ſweet water, and uſed in dreſſing the victuals of the moſt delicate.

The virtues of lime-water do not depend on its abſorbency; and it may as juſtly be called antalkaline, as antacid.

Lime-water prevents, or long protracts, the putrefaction of animal ſubſtances. Dr. Alſton alſo thinks that quick-lime in a ſhip's well would effectually prevent the corruption of the water, and conſequently the putrid ſteams, or foul air, thence ariſing, which ſometimes prove fatal to the crew.

The virtues of lime-water outwardly applied in many diſeaſes of the ſkin, in excoriations, ulcers, gangrenes, &c. are well known. Perhaps there is not a better gargariſm for ſeveral ſorts of ſores in the mouth and throat than lime-water. It has alſo been known to be of great uſe in the tooth-ache. Inwardly taken, lime-water has all the virtues of pure element, which are not a few; and on which probably depend the good effects of mineral waters, more than on the minerals they contain. Dr. Alſton never found it cauſed thirſt; on the contrary, he found it quenched thirſt as well as ſimple water, and cuſtom rendered it agreeable. Lime-water is notably detergent and attenuating, even more ſo than ſoap itſelf, of mucous, viſcid, and other animal ſordes, which makes it preferable, in many caſes, to the pureſt, as well as to mineral waters. In a word, lime-water may be ſaid, in general, to purify the blood, with as good reaſon, as any other medicine whatever, eſpecially from any putrid, purulent, or ſcorbutic foulneſſes.

Dr. Lewis obſerves, that lime-water, drank to the quantity of a quarter of a pint three or four times a day, has been found ſerviceable in ſcrofulous complaints, fluxes, ſeminal weakneſſes, and other diſorders proceeding from an impurity of the fluids, or laxity and debility of the ſolids. It generally promotes urine; oftentimes the cuticular diſcharge; and, where the ſtomach is oppreſſed with viſcid phlegm, expectoration. It for the moſt part binds the belly, and ſometimes occaſions a troubleſome coſtiveneſs, unleſs this effect be occaſionally provided againſt by the interpoſition of proper laxatives. It anſwers beſt in cold, ſluggiſh, phlegmatic, and corpulent habits; and is to be uſed more cautiouſly in hot, bilious diſpoſitions, and where the patient is much emaciated, or the appetite weak, and at the time of any critical or periodical evacuation. It has been cuſtomary to impregnate lime-water with different materials, partly for rendering it more acceptable to the palate and ſtomach, and partly for improving its medicinal efficacy againſt cutaneous defedations. The college of Edinburgh directed, in this view, three ounces of the ſhavings of the wood and bark of ſaſſafras, one ounce and a half of ſhaved liquorice, and four drams and a half of bruiſed nutmegs; the college of London, half an ounce of ſaſſafras bark, and one ounce of liquorice, with the addition, in ſome caſes, of four ounces of raſped guaiacum wood, and three drachms of coriander ſeeds; to be macerated for four days in three quarts of lime-water, and the liquid ſtrained off for uſe. Theſe infuſions are taken in the ſame quantities as the ſimple lime-water, by themſelves, or with the addition of milk. Lewis's Mat. Med.

But Dr. Macbride obſerves, that the activity of lime-water is impaired by infuſing vegetable ſubſtances therein, which contain much fixed air, ſuch as the guaiacum or ſaſſafras; for theſe woods, abounding in reſin, give out their cementing principle, which, uniting with the diſſolved quick lime, reſtores it to its original ſtate of an inactive calcareous earth: therefore, when it is intended that theſe woods, or any other ſubſtance of the like nature, ſhould give out their virtue to lime-water, and that the water ſhould, at the ſame time, contain its due proportion of diſſolved lime, ſome quick-lime ought to be added, during the time of maceration. He alſo obſerves, that as milk contains a large proportion of fixed air, it ought not to be mixed with lime-water, ſince it muſt neceſſarily take off from its activity. To the ſame purpoſe, Dr. Alſton has obſerved, that there is ſcarcely any thing that is uſually mixed and given along with lime-water, that does not, more or leſs, deſtroy its efficacy; for which reaſon he recommended it always to be taken alone. Macbride's Eſſays, p. 250. 271.

It is obſerved by Dr. Lewis, that lime-water diſſolves, by the aſſiſtance of heat, mineral ſulphur, vegetable oils and reſins, and animal fats. It extracts alſo, in the cold, the virtues of ſundry reſinous and oily vegetables, and diſſolves thick phlegm, and mucous matters, and the curd of milk, with which laſt it forms a white liquid, nearly ſimilar to milk in its natural ſtate. But the diſſolvent power of quick-lime has been evinced by Dr. Macbride, and ſhewn to extend to a variety of different ſubſtances, as camphor, myrrh, gum guaiacum, aſa fœtida, aloes, caſtor, balſam of Tolu, maſtich, jalap, and the cortex Peruvianus, which were found to yield ſtrong ſolutions and tinctures; and theſe, he ſays, are more elegant medicines, and perhaps may be found more efficacious than the ſpirituous tinctures, ſince they will never become turbid, or ſeparate on being mixed in any watery vehicle. And ſince the ſolvent power of quick-lime is found to depend on its depriving certain ſubſtances of that fixed air or carbonic acid, which is their cementing principle, it was natural to imagine that it might be uſefully applied to the ſolution of the human calculus or ſtone.

Of the various ſubſtances examined by Dr. Hales, with a view of determining their reſpective quantities of fixed air, the human calculus was found to contain the largeſt proportion; above one-half of this maſs conſiſting of fixed air. Nevertheleſs, if the cauſtic alkali, or lime-water, could be ſafely conveyed to it, theſe would abſorb the fixed air, and the earthy parts, deprived of what bound them together, muſt preſently fall to pieces. That lime-water is lithontriptic has been ſhewn ſufficiently by Dr. Hales, and more fully by Dr. Whytt. See his Eſſay on the virtues of Lime-water, in the Cure of the Stone, and Edinb. Eſſ. &c. vol. i. art. 13. p. 383. vol. v. art. 69.

This gentleman prefers calcined oyſter-ſhell lime-water to any other; which, he ſays, proves a more active menſtruum for this concrete, than that made from the ſtone limes; the diſſolving power of the oyſter-ſhell lime-water ſeeming, from Dr. Whytt's experiments, to be more than double to that of the ſtone lime-waters. Dr. Alſton ſeems to think this a matter of indifference; and was himſelf cured chiefly by the ſtone quick-lime water before mentioned. This lithontriptic quality of lime-water has been farther confirmed by Dr. Alſton, who has ſhewn the efficacy of lime-water in this reſpect, not only when made by the firſt infuſion, and aſſiſted by artificial heat, but even after fifty or more infuſions, and in the common air. The doctor thinks that the energy of lime-water in this caſe probably conſiſts in its penetrating detergency, whereby, inſinuating itſelf among the ſolid parts of the calculi, or into their pores, it ſeparates them, or diminiſhes their coheſion, but does not diſſolve them. See LITHONTRIPTIC.

But the efficacy of quick-lime and cauſtic alkali in this intention, is now known to depend principally, if not entirely, on its power of abſorbing the air, which binds calculous ſubſtances together. However, the alkali, when combined with oil, and made into ſoap, is not only ſo greatly obtunded thereby, as to loſe much of its power, but the ſoap itſelf is ſo nauſeous, that few perſons can be induced to take it in a quantity ſufficient to prove of much effect: it would, therefore, be a happy diſcovery if any vehicle could be found out that would ſheathe the acrimony of the cauſtic alkali, ſo as to allow it to be taken in large and continued doſes. Poſſibly, ſays Dr. Macbride, veal broth, or a decoction of marſhmallow roots, might be found to anſwer this purpoſe; and lime-water might be taken at the ſame time, which would not at all interfere with the operation of the alkali, but rather add to its activity. Dr. Chittick's noſtrum, which is found, after a perſeverance of ſome months, actually to diſſolve the ſtone, is ſaid to be nothing more than the cauſtic alkali, given in veal broth. But lime-water, when taken alone, muſt often fail in producing any conſiderable effect as a lithontriptic, becauſe it will loſe much of its power, as Dr. Macbride has ſhewn, from the fixed air of the alimentary ſubſtances in the firſt paſſages, who, therefore, recommends it to be drank when the ſtomach is empty; and alſo, as Dr. Whytt and Dr. Macbride have proved by experiments, from the fixed air of the urine itſelf, which will ſaturate great part of the quick-lime, even when it hath reached the bladder. Macbride's Eſſays, eſſ. 5. paſſim.

Since there is but a ſmall proportion of lime in the water, it may be thought that taking a few grains of the quick-lime in ſubſtance would prove much more effectual in the ſtone, than large quantities of lime-water. But this is a miſtake; and hence Mrs. Stephens's egg-ſhells and ſnail-ſhells, if burnt to quick-lime, can never be equally ſucceſsful with lime-water for the ſtone.

As for the *aquæ benedictæ compoſitæ*, or compound lime-waters, they are not to be compared with ſimple lime-water in the gravel; nor, in Dr. Alſton's opinion, in any diſeaſe requiring this water.

The doctor adds, in his Appendix, that though he cannot yet determine how far lime-water may be proper, even in acute diſtempers, yet he has found it ſafe in feveriſh colds; and by the caſes he there mentions, it ſeems probable that lime-water, by its diluent and diuretic qualities, may prove more uſeful in fevers than is at preſent believed.

However this may prove on farther trials, it may be ſaid, in general, that lime-water is diluent, detergent, antiſeptic, anthelmintic, diuretic, and vulnerary; uſeful in all diſeaſes proceeding from, or accompanied with, obſtructions in the bowels or glands, viſcid phlegm, calculous concretions, or putrefaction; and commended for the ſcurvy, ſcrophulæ, gravel, conſumptions, empyema-aſthma, arthritis vaga, œdematous ſwellings, diabetes, fluor albus, fluxes, &c. and outwardly for diſeaſes of the ſkin, ulcers, gangrenes, &c. It may be taken to the quantity of a pound, once, twice, or thrice a day; or uſed for common drink. See Dr. Alſton's Diſſertation on Quick-lime, and Lime-water, Edinb. 1752. See LITHONTRIPTIC.

LIME-*Water*, in *Gardening*, an uſeful kind of water, which is prepared by ſlaking cauſtic lime in ſoft water, in the proportion of half a peck of the former to thirty-two gallons of the latter, letting them remain ſome time before they are made uſe of, ſtirring them well, two or three times a day, for two or three days. It is a liquid which, when the lime has ſubſided, is found highly uſeful in clearing fruit-trees from the ravages of the Aphis puceron, or vine-fretter. It ſhould be applied once a day by means of an engine, ſo as to be thrown as much as poſſible on the under ſides of the leaves, and with conſiderable force, preſſing the fore finger upon the end of the pipe, to make it ſpread like ſmall rain, and taking care that every part of the tree be well watered. It ſhould be done as much as poſſible in cloudy weather, and when the ſun is off the walls. Where the trees have an eaſterly aſpect, they may be watered about half-paſt eleven o'clock in the forenoon, and in a northern one, the firſt thing in the morning; but in a ſouthern aſpect, about four o'clock in the afternoon. But when northerly or eaſterly winds and froſty nights prevail, it ſhould be diſcontinued till the weather becomes mild. The trees ſhould always get dry before night, and never be watered when the ſun is upon them. Care muſt likewiſe be taken that the grounds of the lime be not made uſe of, as it would make the trees have a diſagreeable appearance, and perhaps be injurious. See PUCERON and VINE-FRETTER.

LIME-*Work*, ſuch works or kilns as are conſtantly employed in the manufacturing of lime. A late writer has thought it neceſſary, that the managers of eſtates ſhould underſtand the nature of this ſort of manufacture, though it is ſeldom neceſſary or eligible for a large proprietor of land to carry on his own lime-works, "unleſs during a limited time, at the outſet of new works, to aſcertain their value," as there are always enterpriſing men who will give more rent for a work, than the profits ariſing from it to a proprietor, even when under the direction and management of the moſt faithful perſon. They and the lands attached to them ſhould rather be conſidered by ſuch proprietors as farms, the building of kilns and ſheds as erecting farm offices, and the laying out and conſtructing of roads, railways, &c. as general improvements of their eſtate; the tenants agreeing to work the quarries agreeable to articles, and to keep the kilns, building, and roads in ſtates of proper repair.

LIME, in *Geography*, a town of America, in Grafton county, New Hampſhire, ſituated on the E. bank of Connecticut river; 12 miles N. of Dartmouth college, and containing 1318 inhabitants.

LIMER, LYEMMER, or *Lime-hounds*. See *Blood*-HOUND and DOG.

LIMERICK, in *Geography*, a county of Ireland, in the province of Munſter, called from the town of the ſame name, which was, from the earlieſt times in Iriſh hiſtory, a place of conſiderable importance. At the time when the Iriſh chieftains did homage to Henry II. Daniel O'Brien, king of Limerick, was of the number. This prince appears to have been alſo ſovereign of Clare, which was then called Thomond. Limerick is bounded on the north by the counties of Clare and Tipperary, being ſeparated from the former by the river Shannon, on the weſt by Kerry, on the ſouth by Cork, and on the eaſt by Tipperary. Its length from eaſt to weſt is 40 Iriſh (51 Engliſh) miles. Its breadth from north to ſouth 25 Iriſh (32 Engliſh) miles. It contains 386,750 acres, or 604 ſquare miles Iriſh, equal to 622,975 acres, or 970 ſquare miles Engliſh. There are 125 pariſhes, which by unions form 60 benefices, of which 33 only had pariſh churches at the time Dr. Beaufort publiſhed. The pariſhes are moſtly in the dioceſes of Limerick and Emly. The population was ſtated by Dr. Beaufort at 170,000, but it muſt have conſiderably increaſed. The ſoil of Limerick is extremely good for tillage, and very productive of graſs; eſpecially thoſe grounds which are called the *coreachs*, whoſe fertility is proverbial, and is cauſed by the rich manure which is annually depoſited by the overflowings of the Shannon. The heavieſt and fatteſt beaſts that are ſlaughtered at Cork are fed in this county; much butter is exported from it; the orchards produce a very fine cyder, and it is by no means deſtitute of trees and plantations. The paſture ſyſtem, which has been on the decline in moſt parts of Ireland ſince the introduction of corn bounties, propoſed by that enlightened friend of his country, the Rt. Hon. John Foſter, when chancellor of the exchequer, ſtill continues in Limerick, but is on the decline. Even when Mr. Young wrote in 1778, he obſerved a great increaſe of tillage; "thrice the corn grown that there was formerly; much paſturage broken up on this account, ſome bullock land and ſome ſheep land." The ſame intelligent writer alſo ſpeaks of improvement in the ſtate of the poor, but this ſtill wants amelioration. Limerick, though diverſified by ſmall hills, is not at all mountainous, except on the ſouth-eaſt, where it is bounded by the Galtees, a ridge of formidable mountains, that extend into Tipperary, and on the borders of Kerry, where it grows uneven, and forms a grand amphitheatre of low but ſteep mountains, which extends in a wide curve from Loghil to Drumcollohen. In the firſt of theſe riſes the river Maig, which croſſes the county, and falls into the Shannon; as do many fine ſtreams by which it is plentifully watered. In the weſtern hills are the ſources of the Feale and the Gale, which run weſtward through Kerry, and of the *Black* water which flows in a contrary direction through the county of Cork. Limerick is the county town; for which ſee the next article. There are no other towns of conſequence. A colony of palatines from Germany was ſettled in this county about a century ago, by a former lord Southwell. Of theſe Mr. Young mentions ſome particulars which are intereſting. "They have in general leaſes for three lives, or 31 years, and are not cottars to any farmer, but if they work for them, are paid in money. The quantities of land are ſmall, and ſome of them have their feeding land in common by agreement. They are different from the Iriſh in ſeveral particulars; they put their potatoes in with the plough in drills, horſe-hoe them while growing, and plough them out. One-third of the dung does in this method, for they put it only in the furrows, but the crops are not ſo large as in the common method. They plough without a driver: a boy of twelve has been known to plough and drive four horſes, and ſome of them have a hopper in the body of their ploughs, which ſows the land at the ſame time it is ploughed. Their courſe of crops, 1. Potatoes, 2. Wheat, 3. Wheat, 4. Oats; or 1. Potatoes, 2. Barley, 3. Wheat, 4. Oats: in which management they keep their land many years, never laying it out as their neighbours do. They preſerve ſome of their German cuſtoms; they ſleep between two beds: they appoint a burgomaſter, to whom they appeal in caſe of all diſputes;

and they yet (1778) preſerve their language, but that is declining. They are very induſtrious, and in conſequence are much happier, and better fed, clothed, and lodged, than the Iriſh peaſants. We muſt not however conclude from thence, that all is owing to this; their being independent of other farmers, and having leaſes, are circumſtances which will create induſtry. Their crops are much better than thoſe of their neighbours. There are three villages of them, about 70 families in all. For ſome time after they ſettled, they fed upon ſour crout, but by degrees left it off, and took to potatoes; but now ſubſiſt upon them and butter and milk, but with a great deal of oat bread, and ſome of wheat, ſome meat and fowls, of which they raiſe many. They have all offices to their houſes, that is, ſtables and cow-houſes, and a lodge for their ploughs, &c. They keep their cows in the houſe in winter, feeding them upon hay and oat ſtraw. They are remarkable for the goodneſs and cleanlineſs of their houſes. The women are very induſtrious, reap the corn, plough the ground ſometimes, and do whatever work may be going on; they alſo ſpin, and make their children do the ſame." The late Silver Oliver, eſq. of Caſtle Oliver, planted another colony, taken from this firſt, of about 66 families, amounting to 700 Proteſtants, on his eſtate, and of theſe Mr. Young gives a ſimilar account. But with theſe exceptions, the huſbandry of the county of Limerick is perhaps the work in Munſter, which is attributed to the natural richneſs of the ſoil, and to the greater prevalence of the grazing ſyſtem. Mr. Young ſays, that the rich land reaches from Charleville, at the foot of the mountains, to Tipperary by Kilfenning, a line of 25 miles, and acroſs from Ardpetuch to within four miles of Limerick 16 miles. Bruff, Kilmallock, and Hoſpital have very good land about them; the quantity in the whole conjectured to be 100,000 acres. This is chiefly under bullocks. The corceſſes on the Shannon are from two to three miles broad. There is alſo a light lime-ſtone land, for ſheep and cows. Mr. Young, ſpeaking of the land near Caſtle Oliver, in the rich diſtrict, ſays, "it is a rich, mellow, crumbling, putrid, ſandy loam, 18 inches to three feet deep, the colour a reddiſh-brown. It is dry ſound land, and would do for turnips exceedingly well, for carrots, for cabbages, in a word for every thing. I think, upon the whole, it is the richeſt ſoil I ever ſaw, and ſuch as is applicable to every purpoſe you can wiſh; it will fat the largeſt bullock, and at the ſame time do equally well for ſheep, for tillage, for turnips, for wheat, for beans, and in a word for every crop and circumſtance of profitable huſbandry." After ſome other particulars he concludes thus: "The face of the country is that of deſolation; the grounds are over-run with thiſtles, ragwort, &c. to exceſs; the fences are mounds of earth, full of gaps; there is no wood, and the general countenance is ſuch that you muſt examine into the ſoil before you will believe that a country, which has ſo beggarly an appearance, can be ſo rich and fertile." Theſe remarks were written above 30 years ago, and improvement has ſince taken place, but they are ſtill too applicable. Limerick is repreſented in the imperial parliament by three members, two for the county, and one for the city. This county has not yet had a ſtatiſtical account of it publiſhed. Beaufort. Young.

Limerick, a city of Ireland, capital of the county of the ſame name, ſtrongly ſituated on the river Shannon, on an iſland in which it is partly built. It is a poſt-town, and is repreſented in parliament. The new port, which is connected with the old city by a bridge, is called Newtown Pery, from the Pery family, the head of which is now earl of Limerick, whoſe eſtate it is. The buildings are of brick, large, and uniform, ſo that whilſt the old town has a very ruinous appearance, this port will bear compariſon with the beſt ſtreets in almoſt any other city, except where public buildings contribute to ornament them. The public buildings are not many, or deſerving of much notice. The cuſtom-houſe is a plain building. The cathedral is an ancient and venerable pile. The biſhop's palace is a comfortable modern houſe at the weſt end of the city. The corporation of Limerick is what may be called a cloſe one, as no perſon can be become a freeman, except by favour of the council; freeholders, however, can vote at the election of members of parliament. The magiſtrates are a mayor, two ſheriffs, a recorder, a town-clerk, aldermen and burgeſſes; it hath alſo a military governor, conſtable and town major, and is the reſidence of the general commanding a diſtrict. The population probably exceeds 50,000. The trade of Limerick is very extenſive, and is rapidly increaſing. Its export of corn is perhaps the greateſt in Ireland, and its corn-market is very convenient. It muſt more and more derive benefit from the canal connecting the Shannon with the Liffey. There are ſix churches, a Preſbyterian meeting-houſe, a Methodiſt meeting-houſe, a Quakers' meeting-houſe, and ſeveral chapels for Roman Catholics, who form the greateſt part of the population. There are alſo ſome charitable inſtitutions well attended to, and a public library, lately inſtituted. The inhabitants are reckoned gay and fond of ſociety, and public amuſements are in general well ſupported. Limerick, being naturally a city of ſtrength, and formerly well fortified by art, has always been deemed a place of conſiderable importance. In 1651 it was taken by Ireton, in the ſervice of the parliament, after a vigorous ſiege. In 1690, it was unſucceſsfully beſieged by king William in perſon. In 1691, it ſurrendered to general Ginkle, afterwards earl of Athlone, on terms of capitulation very advantageous to the beſieged, and all who profeſſed the Roman Catholic religion, which are called the *articles of Limerick*. Limerick is 94 Iriſh miles S.W. from Dublin. Beaufort, Young, Carliſle.

Limerick, a biſhopric of Ireland, in the eccleſiaſtical province of Caſhel, united to the biſhoprics of Ardfert and Aghadoe, in the year 1663. The two latter have been long incorporated ſo as to form but one dioceſe; the dignity of archdeacon, and the ruined walls of a church with a round tower, are all the memorials of the biſhopric of Aghadoe that now remain. The whole union comprehends great part of the county of Limerick, the whole of Kerry, and a few pariſhes in the counties of Cork and Clare. There are in all 176 pariſhes, which are united ſo as to form 88 benefices, and of theſe only 47 have churches, and 14 glebe houſes. It is to be remembered, however, that the population is not Proteſtant. Beaufort.

Limerick, a poſt-town of America, in York county and ſtate of Maine, near the confluence of Oſſipee river with Saco, and oppoſite to Gorham; incorporated in 1787, and containing 995 inhabitants.—Alſo, a townſhip in Montgomery county, Pennſylvania, containing 999 inhabitants.

LIMESOL, **Limassol**, or **Limisso**, a town of the iſland of Cyprus, formerly *Nemoſia*, is now in a miſerable ſtate, abounding with ruins and rubbiſh. Its harbour, however, is not a little frequented; here veſſels are loaded with grain, cotton, and other productions of the ſoil. The beſt Cyprus wines are made in its environs, and it is the emporium of all thoſe of the iſland who are concerned in trade. Not far from this town, if it deſerves that appellation, ſtood the ancient "Limaſſol," which ſtill, at a period of remoter antiquity, was called *Amathus*, celebrated for a temple conſecrated to Venus and Adonis, in which was preſerved, according to Pauſanias, a rich necklace of precious ſtones, ornamented with gold, the work of Vulcan, and given in the firſt inſtance to Hermione. But this ancient town is deſtroyed. (See AMATHUS.) Near Limaſſol, E. of it, is the moſt ſouthern promontory of the iſland, formerly named the promontory of *Agrotiri*, at preſent Cape di Gatti or *Gatto*, on account of the great number of cats kept by the monks, who, in the 4th century, obtained permiſſion to eſtabliſh themſelves there, as well as on mount Olympus, on condition of keeping many of thoſe animals for hunting and deſtroying ſnakes, which had multiplied in the iſland. (See GATTO and CYPRUS.) Limaſſol is the ſee of a biſhop, ſuffragan of Nicoſia. N. lat. 34° 45′. E. long. 32° 30′.

LIMESTONE, a poſt-town of America, in Kentucky, on the S. ſide of Ohio river, and on the W. ſide of a ſmall creek of the ſame name. This is the uſual landing place for people who come down in boats with an intention of ſettling in the upper parts of the ſtate, and here the champaign country on the E. ſide of the river begins; four miles N.E. of Waſhington. N. lat. 38° 40′. W. long. 84° 17′.

LIMETREE, in *Gardening*, is a tree of the deciduous kind, occaſionally uſed in plantations for its wood, &c. There are four ſpecies, each of which is capable of being raiſed from layers and cuttings.

It is ſuggeſted by Mr. Nicol, that this ſort of tree ſucceeds in the moſt perfect manner, in "low, deep, ſubhumid loams," but that "in dry gravelly ſoils, it loſes the beautiful gloſs of its foliage, for which it is ſo much admired in the early ſummer ſeaſon."

It may be noticed that the timber of the limetree is uſed by carvers, it being a ſoft light wood; as alſo by architects for framing the models of their buildings, &c. The turners likewiſe uſe it for making light bowls, diſhes, &c. but it is too ſoft for any ſtrong purpoſes. See CITRUS, in *Botany*, *Gardening*, and *Planting*. See alſo TILIA.

LIMETREE *Bay*, in *Geography*, a bay on the S. coaſt of Santa Cruz. N. lat. 17 45′. W. long. 63 27′.

LIMEUM, in *Botany*, appears from Pliny to be a name of Gallic origin for a plant with which the ancient Gauls poiſoned their arrows. This appellation, however, could not have been originally applied to the preſent genus, all the ſpecies of which are natives of the Cape of Good Hope. Linn. Gen. 184. Schreb. 246. Willd. Sp. Pl. v. 2. 291. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. 337. Juſſ. 314. Lamarck Illuſtr. t. 275. Gærtn. t. 76.—Claſs and order, *Heptandria Digynia*. Nat. Ord. *Holeraceæ*, Linn. *Portulaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, permanent, of five, ovate, acuminated, carinated leaves, membranaceous at the margin, two of them exterior. *Cor.* Petals five, equal, ovate, with a ſlight claw, obtuſe, ſhorter than the calyx; nectary forming a margin round the germen, bearing the ſtamens. *Stam.* Filaments ſeven, awl-ſhaped, ſhorter than the corolla; anthers ovate. *Piſt.* Germen ſuperior, globoſe. Style cloven, cylindrical, ſhorter than the ſtamens; ſtigmas rather obtuſe. *Peric.* Capſule globoſe, of two cells. *Seeds* ſolitary, hemiſpherical, hollow.

Obſ. We are induced to follow the opinion of Linnæus reſpecting the capſule of this genus, as it undoubtedly belongs to the *Portulaceæ* of Juſſieu. See Gærtner and Schreber.

Eſſ. Ch. Calyx of five leaves. Petals five, equal. Capſule globoſe, of two cells. Seeds ſolitary, concave.

1. L. *africanum*. Linn Sp. Pl 488. Thunb. Prod. 68.—Leaves oblong, on footſtalks.—A native of the Cape, whence it was brought by Mr. Francis Maſſon into the Royal Garden at Kew in the year 1774. It flowers in June and July. Linnæus juſtly remarks, that this ſpecies has the appearance of *Corrigiola* or *Telephium*. The *root* is perennial. *Stems* proſtrate, feeble, a ſpan long, angulated, naked, perennial at the baſe. *Leaves* alternate, remote, linear-lanceolate, or oblong, about an inch in length. *Corymbs* of green and white *flowers* terminal, ſolitary, compound, naked, on long ſtalks.—Martyn ſays that the leaves of this are ſubject to vary; for that "in the Bankſian herbarium may be ſeen linear, oblong, ovate, roundiſh and ſpatulate leaves, if the ſpecimens be all of one ſpecies."

2. L. *capenſe*. Willd. n. 2. Thunb. Prod. 68. (L. incanum; Mart. Mill. Dict. v. 3. L. aphyllum; Linn. Suppl. 214.)—Leaves ovate, ſeſſile.—It is curious that the younger Linnæus ſhould have given this the ſpecific name of *aphyllum*, remarking that it appears to be without *leaves*, when at the ſame time he deſcribes them as ovate and ſeſſile. Martyn, judging from Maſſon's ſpecimen in the Bankſian herbarium, ſays, that L. *capenſe* is a ſmall plant, extremely woody at the bottom. *Leaves* ovate, almoſt ſeſſile, and as woolly as thoſe of mullein; radical ones numerous; ſtem-leaves fewer.

3. L. *æthiopicum*. Willd. and Thunb.—Leaves linear-lanceolate. This ſpecies is only known from being mentioned by Thunberg and adopted by Willdenow and Martyn. The laſt author juſtly obſerves, that we have a deplorable inſtance, in theſe three ſpecies of *Limeum*, of trivial names which are not given for the ſake of true diſtinction: all the plants being natives of the Cape, though ſeverally called *africanum*, *capenſe*, and *æthiopicum*.

We further learn from profeſſor Martyn, that there is a fourth ſpecies in the Bankſian herbarium, which is truly a ſhrub, and may be called L. *fruticans*.

LIMINGO, in *Geography*, a town of Sweden, in the government of Ulea; 11 miles S. of Ulea.

LIMINGTON, a town of America, in York county, and ſtate of Maine, bounded N. and E. by Saco river; 50 miles N. of York.

LIMIT, in *Mathematics*. See LIMITS.

LIMIT *of diſtinct viſion*, in *Optics*. See *Diſtinct* VISION.

LIMITATION, LIMITATIO, in *Law*, is a certain time aſſigned by ſtatute, within which an action muſt be brought; and limitation of time is two-fold; *viz.* to make title to an inheritance by the common law; and in writs by ſeveral ſtatutes. There is a limitation in real and perſonal actions; and in the former, he that will ſue for any lands or hereditaments, ought to prove, that he or his anceſtors were ſeiſed of the lands ſued for by writ of aſſize, or he cannot maintain his action; and this is called limitation of aſſize. Stat. Weſt. 1. See *Writ of* RIGHT and *Statutes of* LIMITATION *infra*, alſo INFORMATION.

There is no limitation with regard to the time within which any actions touching advowſons are to be brought; at leaſt, none later than the times of Richard I. and Henry III.; for by ſtatute 1 Mar. ſt. 2. c. 5. the ſtatute of limitations, 32 Hen. VIII. c. 2, is declared not to extend to any writ of right of advowſon, *quare impedit*, or aſſiſe of *darrein preſentment*, or *jus patronatus*. And this, ſays judge Blackſtone, upon very good reaſon, becauſe it may very eaſily happen, that the title to an advowſon may not come into queſtion, nor the right have an opportunity of being tried, within 60 years; which is the longeſt period of limitation aſſigned by the ſtatute of Henry VIII. See APPEAL and INDICTMENT.

LIMITATION *of Entry*. See ENTRY.

LIMITATION *of Eſtate*, in a legal ſenſe, imports how long the eſtate ſhall continue, or is rather a qualification of a precedent eſtate. As where one doth give lands to a man to hold to him and his heirs male, and to him and the heirs female, &c. here the daughters ſhall not have any thing in it, ſo long as there is a male; for the eſtate to the heirs male is firſt limited. Co. Litt. 313.

A limitation is denominated by Littleton (§ 380. 1 Inſt. 234.) a "condition in law." For where an eſtate is ſo expreſsly confined and limited by the words of its creation, that it cannot endure for any longer time than till the contingency happens, upon which the eſtate is to fail, this is denominated a "limitation;" as when land is granted to a man, *ſo long* as he is parſon of Dale, or while he continues unmarried, or *until* out of the rents and profits he ſhall have made 500*l.* and the like: (10 Rep. 41.) In ſuch caſe the eſtate determines as ſoon as the contingency happens, and the next ſubſequent eſtate, which depends upon ſuch determination, becomes immediately veſted without any act to be done by him who is next in expectancy. But when an eſtate is, ſtrictly ſpeaking, upon "condition in deed," (as if granted expreſsly *upon condition* to be void upon the payment of 40*l.* by the grantor, or *ſo that* the grantee continues unmarried, or *provided* he goes to York, &c. Rep. 41.) the law permits it to endure beyond the time when ſuch contingency happens, unleſs the grantor, or his heirs or aſſigns, take advantage of the breach of the condition, and make either an entry or a claim, in order to avoid the eſtate. (Litt. § 347. Stat. 32 Hen. VIII. c. 34.) Yet though ſtrict words of condition be uſed in the creation of the eſtate, if on breach of the condition the eſtate be limited over to a third perſon, and does not immediately revert to the grantor or his repreſentatives, (as if an eſtate be granted by A to B, on condition that within two years B intermarry with C, and on failure thereof then to D and his heirs,) this the law conſtrues to be a limitation and not a condition (1 Ventr. 202.); becauſe, if it were a condition, then upon the breach thereof, only A or his repreſentatives could avoid the eſtate by entry, and ſo D's remainder might be defeated by their neglecting to enter; but, when it is a limitation, the eſtate of B determines, and that of D commences, and he may enter on the lands the inſtant that the failure happens. So alſo, if a man by his will deviſes land to his heir at law, on condition that he pays a ſum of money, and for non-payment deviſes it over, this ſhall be conſidered as a limitation; otherwiſe, no advantage could be taken of the non-payment, for none but the heir himſelf could have entered for a breach of condition. Cro. Eliz. 201. 1 Roll. Abr. 411. Blackſt. Com. b. ii.

LIMITATION *of the Crown.* The ſtatutes 1 W. & M. cap. 8. 12 W. III. cap. 2. and 1 & 2 Ann. cap. 17. 4 Ann. cap. 8. &c. are acts for the limitation of the crown, and ſettling it on Proteſtant heirs in the houſe of Hanover. See CROWN.

LIMITATION, *Statutes of*, a ſpecies of plea in bar, in which a perſon may plead the time limited by certain acts of parliament, beyond which no plaintiff can lay his cauſe of action. This, by the ſtatute of 32 Hen. VIII. c. 2. in a writ of right is *ſixty* years; in aſſiſes, writs of entry, or other poſſeſſory actions real, of the ſeiſin of one's anceſtors, in lands; and either of their ſeiſin, or one's own, in rents, ſuits, and ſervices, *fifty* years; and in actions real for lands grounded upon one's own ſeiſin or poſſeſſion, ſuch poſſeſſion muſt have been within *thirty* years. By ſtat. 1 Mar. ſt. 2. c. 5. this limitation does not extend to any ſuit for advowſons. (See above.) But by the ſtatute 21 Jac. I. c. 2. a time of limitation was extended to the caſe of the king, *viz. ſixty* years precedent to 19th February, 1623. (3 Inſt. 183.); but this becoming ineffectual by efflux of time, the ſame date of limitation was fixed by ſtatute 9 Geo. III. c. 16. to commence, and be reckoned backwards, from the time of beginning any ſuit, or other proceſs, to recover the thing in queſtion; ſo that a poſſeſſion for *ſixty* years is now a bar even againſt the prerogative, in derogation of the ancient maxim "nullum tempus occurrit regi." By another ſtatute, 21 Jac. I. c. 16, *twenty* years are the time of limitation in any writ of formedon; and by conſequence, *twenty* years are alſo the limitation in every action of ejectment; for no ejectment can be brought, unleſs where the leſſor of the plaintiff is entitled to enter on the lands; and by the ſtatute 21 Jac. I. c. 16. no entry can be made by any man, unleſs within *twenty* years after his right ſhall accrue. Alſo, all actions of treſpaſs (*quare clauſum fregit*, or otherwiſe) detinue, trover, replevin, account, and caſe, (except upon accounts between merchants), debt on ſimple contract, or for arrears of rent, are limited by the ſtatute laſt-mentioned to *ſix* years, after the cauſe of action commenced; and actions of aſſault, menace, battery, mayhem, and impriſonment, muſt be brought within *four* years, and actions for words within *two* years after the injury committed. And by the ſtatute 31 Eliz. c. 5. all ſuits, indictments, and informations, upon any penal ſtatutes, where any forfeiture is to the crown alone, ſhall be ſued within *two* years, and where the forfeiture is to a ſubject, or to the crown and a ſubject, within *one* year after the offence committed; unleſs where any other time is ſpecially limited by the ſtatute. Laſtly, by ſtatute 10 W. III. c. 14, no writ of error, *ſcire facias*, or other ſuit, ſhall be brought to reverſe any judgment, fine, or recovery for error, unleſs it be proſecuted within *twenty* years. The uſe of theſe ſtatutes of limitation is to preſerve the peace of the kingdom, and to prevent thoſe innumerable perjuries which might enſue, if a man were allowed to bring an action for any injury committed at any diſtance of time. Upon both theſe accounts the law therefore holds, that "*intereſt reipublicæ ut ſit finis litium*," and upon the ſame principle the Athenian laws in general prohibited all actions, where the injury was committed *five* years before the complaint was made. If, therefore, in any ſuit, the injury or cauſe of action happened earlier than the period expreſsly limited by law, the defendant may plead the ſtatutes of limitations in bar; as upon an *aſſumpſit*, or promiſe to pay money to the plaintiff, the defendant may plead *non aſſumpſit infra ſex annos*; he made no ſuch promiſe within ſix years; which is an effectual bar to the complaint. Blackſt. Com. b. iii.

LIMITED FEES, denote ſuch eſtates of inheritance as are clogged or confined with conditions, or qualifications of any ſort. Theſe are of two ſorts, *viz. qualified* or *baſe-fees*, and *fees-conditional*, or *fees-tail*. See *Baſe*-FEES, and FEES-*tail*.

LIMITED *Problem*, is that which admits but of one ſolution, or which can only be ſolved one way: as to make a circle paſs through three points given, not lying in a right line, to deſcribe an equilateral triangle on a line given, &c. See PROBLEM, and DETERMINATE.

LIMITROPHOUS COLUMN. See COLUMN.

LIMITS, in *Mathematics*, a term ſometimes uſed, in general, for quantities, one of which is greater, and the other leſs than another quantity. Thus, in the quantities, a, x, b, if a be leſs than x, and b be greater than x, a and b are ſaid to be limits of x. The word occurs in this ſenſe, when we ſpeak of the limits of the roots of equations.

Sometimes a quantity is ſaid to be a limit between two others, when it is greater than the one and leſs than the other. So a ratio is ſaid to be a limit between two other ratios,

ratios, when it is greater than the one, and leſs than the other.

But limit is often uſed in a more reſtricted ſenſe; thus, when a variable quantity approaches continually to ſome determinate quantity, and may come nearer to it than to have any given difference, but can never go beyond it; then is the determinate quantity ſaid to be the limit of the variable quantity.

Hence, the circle may be ſaid to be the limit of its circumſcribed and inſcribed polygons; becauſe theſe, by increaſing the number of their ſides, can be made to differ from the circle leſs than by any ſpace that can be propoſed, how ſmall ſoever.

The limit of a variable ratio, is ſome determinate ratio, to which the variable ratio may continually approach, and come nearer to it than to have any given difference, but can never go beyond it. Hence, the ratio of the ordinate to the ſub-tangent of a curve, is ſaid to be the limit of the variable ratio of the differences of the ordinates, to the differences of the abſciſſæ.

The word limit, in this ſenſe, ſignifies the ſame as what ſir Iſaac Newton calls a firſt or prime, and a laſt or ultimate ratio.

There are two caſes of a variable quantity, or variable ratio, tending to ſuch a limit, as we have been deſcribing. In the firſt caſe, the variable quantity, or ratio, will not only approach to its limit within leſs than any given differences, but will actually arrive at its limit.

In the ſecond caſe, the variable quantity, or ratio, will only approach its limit within leſs than any given difference, but will never actually arrive at it.

Sir Iſaac Newton, to avoid the harſhneſs of the hypotheſis of indiviſibles, and the tediouſneſs of demonſtrations, according to the method of the ancients, by deductions *ad abſurdum*, has premiſed ſeveral lemmata, in the firſt ſection of the firſt book of his Principles, relating to the firſt and laſt ſums, and ratios of naſcent and evaneſcent quantities; that is, to the limits of ſums and ratios. This doctrine chiefly depends on the firſt of thoſe lemmata; the words of which are, "Quantitates ut & quantitatum rationes, quæ ad æqualitatem tempore quovis finito conſtanter tendunt, & ante finem temporis illius propius ad invicem accedunt quam pro data quavis differentia, fiunt ultimo æquales."

The learned gentlemen, who have written in defence of ſir Iſaac, againſt the author of the Analyſt, are not agreed among themſelves as to the preciſe meaning of this lemma. One of theſe gentlemen ſays, that the genuine meaning of this propoſition is, that thoſe quantities are to be eſteemed ultimately equal, and thoſe ratios ultimately the ſame, which are perpetually to each other, in ſuch a manner, that any difference, how minute ſoever, being given, a finite time may be aſſigned, before the end of which, the difference of thoſe quantities, or ratios, ſhall become leſs than that given difference. See Pref. State of the Rep. of Letters for Oct. 1735, and for Oct. 1736.

What ſir Iſaac Newton intends we ſhould underſtand by the ultimate equality of magnitudes, and the ultimate identity of the ratios propoſed in this lemma, will be beſt known from the demonſtration annexed to it. By that it appears, ſir Iſaac Newton did not mean that any point of time was aſſignable, wherein theſe varying magnitudes would become actually equal, or the ratios really the ſame; but only that no difference whatever could be named, which they ſhould not paſs. The ordinate of any diameter of an hyperbola, is always leſs than the ſame continued to the aſymptote; yet the demonſtration of this lemma can be applied, without changing a ſingle word, to prove their ultimate equality. The ſame is evident from the lemma immediately following, where parallelograms are inſcribed, and others circumſcribed to a curvilinear ſpace. Here the firſt lemma is applied to prove, that by multiplying the number, and diminiſhing the breadth of theſe parallelograms *in infinitum*, that is, perpetually and without end, the inſcribed and circumſcribed figures become ultimately equal to the curvilinear ſpace, and to each other; whereas, it is evident, that no point of time can be aſſigned, wherein they are actually equal; to ſuppoſe this were to aſſert, that the variation aſcribed to the figures, though endleſs, could be brought to a period, and be perfectly accompliſhed; and thus we ſhould return to the unintelligible language of indiviſibles. The excellence of this method conſiſts in making the ſame advantage of this endleſs approximation towards equality, as by the uſe of indiviſibles, without being involved in the abſurdities of that doctrine. In ſhort, the difference between theſe two may be thus explained.

There are but three ways in nature of comparing ſpaces: one is by ſhewing them to conſiſt of ſuch, as by impoſition on each other will appear to occupy the ſame place: another is, by ſhewing their proportion to ſome third; and this method can only be directly applied to the like ſpaces as the former; for this proportion muſt be finally determined by ſhewing when the multiples of ſuch ſpaces are equal, and when they differ: the third method to be uſed, where theſe other two fail, is by deſcribing upon the ſpaces in queſtion ſuch figures as may be compared by the former methods; and thence deducing the relation between thoſe ſpaces, by that indirect manner of proof, commonly called *deductio ad abſurdum*; and this is as concluſive a demonſtration as any other, it being indubitable, that thoſe things are equal which have no difference. Thus Euclid and Archimedes demonſtrate all they have written concerning the compariſon and menſuration of curvilinear ſpaces. The method advanced by ſir Iſaac Newton for the ſame purpoſe differs from their's, only by applying this indirect form of proof to ſome general propoſitions, and from thence deducing the reſt by a direct form of reaſoning. Whoever compares the fourth of ſir Iſaac Newton's lemmas with the firſt, will ſee, that the proof of the curvilinear ſpaces, there conſidered, having the proportion named, depends wholly upon this, that if otherwiſe the figure inſcribed within one of them, could not approach, by ſome certain diſtance, to the magnitude of that ſpace: and this is preciſely the form of reaſoning, whereby Euclid proves the proportion between the different circles. As this method of reaſoning is very diffuſively ſet out in the writings of the ancients; and ſir Iſaac Newton has here expreſſed himſelf with that brevity, that the turn of his argument may poſſibly eſcape the unwary, the reading of the ancients muſt be the beſt introduction to the knowledge of his method. The impoſſible attempt of comparing curvilinear ſpaces, without having any recourſe to the forementioned indirect method of arguing, produced the abſurdity of indiviſibles.

As the magnitudes, called in this lemma ultimately equal, may never abſolutely exiſt under that equality; ſo the varying magnitudes holding to each other the variable ratios, here conſidered, may never exiſt under that, which is here called the ultimate ratio. Of this ſir Iſaac Newton gives an inſtance, from lines increaſing together by equal additions, and having from the firſt a given difference. For the ultimate ratio of theſe lines, in the ſenſe of this lemma, as ſir Iſaac Newton himſelf obſerves, will be the ratio of equality, though theſe lines can never have this ratio; ſince no point of time can be aſſigned, when one does not exceed the other.

In like manner, the quantities called by ſir Iſaac Newton vaniſhing, may never ſubſiſt under that proportion here eſteemed their ultimate.

In the caſe of drawing tangents to curves, where the ordinate bears the ſame proportion to the ſubtangent, as that wherewith the difference of the ordinates, to the difference of the abſciſſæ, vaniſh; theſe lines muſt not be conceived, by the name of an evaneſcent, or any other appellation, ever to ſubſiſt under that proportion: for ſhould we conceive theſe lines, in any manner, to ſubſiſt under this proportion, though at the inſtant of their vaniſhing, we ſhall fall into the unintelligible notion of indiviſibles, by endeavouring to repreſent, to the imagination, ſome inconceivable kind of exiſtence of theſe lines between their having a real magnitude, and becoming abſolutely nothing. Sir Iſaac Newton was himſelf apprehenſive, that this miſtake might be made; for as he thought fit (in compliance with the bad taſte which then prevailed) to continue the uſe of ſome looſe and indiſtinct expreſſions reſembling thoſe of indiviſibles, for which he has himſelf apologized, he expreſsly cautions us againſt miſinterpreting him in this manner, when he ſays: ‘Si quando dixero quantitates quam minimas vel evaneſcentes, vel ultimas, cave intelligas quantitates magnitudine determinatas, ſed cogita ſemper diminuendas ſine limite.’’ Thus expreſsly has he declared to us, that vaniſhing quantities, or whatever other leſs accurate appellation he names them by, are to be conſidered as indeterminate quantities bearing to each other, under their different magnitudes, different proportions; which the quantities themſelves can never obtain, and the limit of theſe proportions is that, for the ſake of which theſe quantities are conſidered: inſomuch, that ſince theſe quantities have different proportions, while they obtain the name of vaniſhing quantities, the term ultimate is neceſſarily added to denote that proportion, which is the limit of an endleſs number of varying ones. The like remark is neceſſary, when theſe quantities are conſidered in the other light, as ariſing before the imagination: for then the proportion intended muſt be ſpecified, by calling it the firſt, or prime proportion of theſe quantities. And as this additional epithet is neceſſary to expreſs the proportion intended, ſo it is abſurd to apply it to the quantities themſelves; as ſir Iſaac Newton ſays, there are "rationes primæ quantitatum naſcentium," but not "quantitates primæ naſcentes." Philoſoph. Tranſactions, N° 342, p. 205.

So that, according to the author we have been quoting, all the examples given by ſir Iſaac in the before mentioned ſection, are to be underſtood of ſuch limits or ultimate ratios, as are never attained to by the quantities and ratios limited, but to which theſe may approach indefinitely, that is, ſo as to differ leſs than by a given quantity.

On the other hand, a learned gentleman, who aſſumed the name of Philalethes Cantabrigienſis, thinks that ſir Iſaac means, by the words of the lemma, and proves, in his demonſtration, not that the quantities or ratios are barely to be conſidered as ultimately becoming equal, or are to be eſteemed as ultimately equal; though, in reality, they can never have that proportion to each other; but that they do at laſt become actually, perfectly, and abſolutely equal. Preſ. State of the Republic of Letters for November 1735, p. 371.

He alſo diſtinguiſhes, as above, between quantities and ratios which arrive at their limits, and thoſe which do not. And it is inſiſted on, that every one of the examples given in the lemmata of this firſt ſection of the firſt book of ſir Iſaac's Principles, are of ſuch quantities and ratios as actually arrive at their reſpective limits; nor is there an inſtance there given of a quantity, or ratio, which never arrives at its limit, except one at the latter end of the ſcholium of this ſection (and that by way of illuſtration of a particular objection only) of two quantities, having a given difference, and being equally increaſed, *ad infinitum*, and whoſe ratio, it is admitted, never arrives at its limit. But decreaſing quantities may really and in fact be diminiſhed *ad infinitum:* for they may vaniſh and come to nothing. The ratio, therefore, of theſe, ſays he, may arrive at its limit; though that of the others cannot.

Neither are theſe learned gentlemen agreed as to the ſenſe of the word *vaniſhing* or *evaneſcent*, in the ſcholium of this firſt ſection of ſir Iſaac's Principles.

The queſtion is, whether the quantities that vaniſh are underſtood to ſpend ſome finite time in vaniſhing, or to vaniſh in an inſtant, or point of time; and conſequently, whether they bear one to another an infinite number of different ſucceſſive ratios during the vaniſhing, or one ratio only, at the point or inſtance of their evaneſcence.

This laſt is the ſenſe in which Philalethes takes the word evaneſcent, or vaniſhing; and the diſpute, on this head, as he obſerves, is of no other conſequence than to determine, whether the ſenſe in which he uſes the word be agreeable to ſir Iſaac Newton's. For, if the quantities vaniſh in an inſtant, I take the only ratio with which they vaniſh; or they ſpend a finite time in vaniſhing, and I take the laſt of the ratios, which they ſucceſſively bear to one another during that time; ſtill the ratio, taken in either of theſe caſes, will be one and the ſame. Preſent State of the Republic of Letters for November 1735, p. 383, 384.

We cannot pretend to give the whole detail of this controverſy, but muſt refer the curious to the Preſent State of the Republic of Letters for 1735. We ſhall only obſerve, that this diſquiſition is partly critical and partly ſcientifical. The critical inquiry is into the ſenſe of ſir Iſaac, ſo far as it may be determined from his own words; and here we cannot help thinking that this is ſomewhat doubtful. The other inquiry is about the true or ſcientifical notion, upon which this doctrine ought to be founded. With reſpect to which we ſhall only aſk two queſtions, which every reader may reſolve for himſelf, to wit, whether the conception or notion he has of the ratio or proportion of evaneſcent quantities, at the point or inſtance of their evaneſcence, be more clear and diſtinct than the notion of infiniteſimals? And whether the notion of inſcribed or circumſcribed polygons to any curve, attaining their laſt form, and thereby coinciding with their curvilinear limit, be more clear and diſtinct than the notion of polygons of an infinite number of ſides in the method of infiniteſimals?

Before we leave this ſubject, it may be proper to give the ſentiments of an eminent mathematician about the doctrine of limits, or of prime and ultimate ratios, and to ſhew the connection of this doctrine with that of fluxions. Mr. Maclaurin, in his Treat. of Flux., art. 502.

Sir Iſaac Newton conſiders the ſimultaneous increments of flowing quantities as finite, and then inveſtigates the ratio which is the limit of the various proportions which thoſe increments bear to each other, while he ſuppoſes them to decreaſe together til they vaniſh; which ratio is the ſame with the ratio of the fluxions. In order to diſcover this limit, he firſt determines the ratio of the increments in general, and reduces it to the moſt ſimple terms, ſo as that (generally ſpeaking) a part at leaſt of each term may be independent of the value of the increments themſelves; then, by ſuppoſing the increments to decreaſe, till they vaniſh, the limit readily appears.

For example, let a be an invariable quantity, x a flowing quantity, and o any increment of x: then the ſimultaneous increments of xx and ax will be $2xo + oo$ and ao, which are in the ſame ratio to each other as $2x + o$ is to a. This ratio of $2x + o$ to a continually decreaſes while o decreaſes, and is always greater than the ratio of $2x$ to a, while o is any real increment; but it is manifeſt, that it continually approaches to the ratio of $2x$ to a as its limit; whence it follows, that the fluxion of xx is to the fluxion of ax, as $2x$ is to a. If x be ſuppoſed to flow uniformly, ax will likewiſe flow uniformly, but xx with a motion continually accelerated; the motion with which ax flows, may be meaſured by ao; but the motion with which $2x$ flows is not to be meaſured by its increment $2xo + oo$, but by the part $2xo$ only, which is generated in conſequence of that motion; and the part oo is to be rejected, becauſe it is generated in conſequence only of the acceleration of the motion with which the variable ſquare flows, while o, the increment of its ſide, is generated; and the ratio of $2xo$ to ao is that of $2x$ to a, which was found to be the limit of the ratio of the increment $2xo + oo$ and ao. See FLUXION.

It is objected againſt ſir Iſaac Newton's method of inveſtigating this limit, that he firſt ſuppoſes that there are increments; that when it is ſaid *let the increment vaniſh*, the former ſuppoſition is deſtroyed, and yet a conſequence of this ſuppoſition, *i. e.* an expreſſion got by virtue thereof, is retained. But the ſuppoſitions that are made in this method of inveſtigating the limit are not ſo contradictory as this objection ſeems to import. He firſt ſuppoſes that there are increments generated, and repreſents their ratios by that of two quantities, one of which is given ſo as not to vary with the increments. If he had afterwards ſuppoſed that no increments had been generated, this indeed had been a ſuppoſition directly contradictory to the former. But when he ſuppoſes thoſe increments to be diminiſhed till they vaniſh, this ſuppoſition ſurely cannot be ſaid to be ſo contradictory to the former as to hinder us from knowing what was the ratio of thoſe increments, at any term of the time, while they had a real exiſtence; how this ratio varied, and to what limit it approached while the increments were continually diminiſhed: on the contrary, this is a very conciſe and juſt method of diſcovering the limit which is required.

It is to be obſerved, that the limiting, prime, or ultimate ratio of increments, ſtrictly ſpeaking, is not the ratio of any real increments whatſoever. But as the tangent of an arch is the right line that limits the poſition of all the ſecants that can paſs through the point of contact, though, ſtrictly ſpeaking, it be no ſecant; ſo a ratio may limit the variable ratios of the increments, though it cannot be ſaid to be the ratio of any real increments. The ratio of the generating motion may be likewiſe ſaid to be the laſt or ultimate ratio of the increments, while they are ſuppoſed to be diminiſhed till they vaniſh, for a like reaſon. It may juſt be added, that there being two caſes of variable quantities and ratios tending to a limit, it might have conduced to perſpicuity, and preventing diſputes, to have diſtinguiſhed theſe different limits by ſome addition. As in the firſt caſe to have called it a limit or ultimate ratio *incluſive;* becauſe the limit is the laſt of the quantities or ratios limited: and in the ſecond to have called it a limit or ultimate ratio *excluſive;* becauſe the quantities limited never attain to the limit, though they approach to it indefinitely.

This diſtinction may perhaps receive ſome farther illuſtration from the following example. It is known that the oſculatory circle is a circle that touches a curve ſo cloſely that no other circle can be drawn through the point of contact between them, all other circles paſſing within or without them both; and hence the oſculatory circle is ſuppoſed to have an equal curvature with the curve at that point. See Mr. Maclaurin's Flux. art. 394.

Now if we conceive the oſculatory circle at the end of the great axis of an ellipſis, it will fall entirely within the ellipſis; and the curvature of the ellipſis and oſculatory circle may both be ſaid to be limits of the curvatures of all the circles falling wholly within, and touching the ellipſis at the end of its great axis. But the term limit will not in both caſes have preciſely the ſame meaning; for the oſculatory circle is a limit *incluſive*, being the laſt of the circles limited; and the ellipſis is a limit *excluſive*, none of the circles limited ever coinciding with it. As to the circles which fall wholly without the ellipſis, and touch it at the end of its great axis, they have no limit *incluſive*, no circle touching the ellipſis ſo cloſely, that no other can paſs between; the only limit here is *excluſive*, the ellipſis itſelf.

The contrary of this happens at the end of the leſſer axis. At any other point of the ellipſis, one half of every oſculatory circle is a limit *incluſive* of the ſemicircles that fall within, and the other half is a limit *excluſive* of thoſe that fall without.

May we not aſk, if a curve is the limit of its inſcribed or circumſcribed polygons in any other ſenſe, than the curvature of the ellipſis is the limit of the curvatures of the circles before deſcribed, which approach nearer and nearer to the curve, but never coincide with it? It is true we hear it often ſaid, that the oſculatory circle is equicurval, and ſo coincides with the ellipſis; but this ſeems a conſequence of the language of infiniteſimals. It would be more accurate to ſay, that the curvature of the ellipſis is the limit *excluſive* of all the before mentioned circles, and that the oſculatory circle is their limit *incluſive*. That excellent geometer, Mr. Simſon, in his Conic Sections, lib. v. prop. 36. cor. ſays only, after demonſtrating the chief property of the oſculatory circle, that *eandem habere cum ſectione conica curvaturam dicitur*, giving this only as an appellation, but not as a propoſition. See on the ſubject of this article, Robins's Diſc. on Fluxions, in his Tracts, vol. ii.

LIMITS *of the Roots of an Equation.*—We have already obſerved, that by finding the limits of the roots of an equation, is to be underſtood the finding of two ſuch numbers, that one ſhall be greater and one leſs than the root required; by which means an approximation is evidently made towards the true root, and the nearer theſe limits approach towards each other, ſo much the more accurate will be the approximation. La Grange, in his "Traité de la Reſolution numerique des Equations," has carried the method of limits to its utmoſt poſſible perfection, by ſhewing, in all equations, how the limits of each of its roots may be aſcertained, and has ſhewn, that the method of approximation employed by Newton, and in fact every method, except that of his own, is defective in this reſpect, *viz.* that between the limits aſcertained in their operation, there may be one, two, or more roots, and conſequently, that they are not neceſſarily the limits of one root, but merely the limits between which one at leaſt of the real roots of the equation muſt lie. The nature of this article will not admit of our entering into an explanation of the proceſs of this celebrated analyſt; we can, therefore, only refer the reader to the work itſelf, and muſt content ourſelves in this place with giving a few of the moſt remarkable caſes relating to the limits of the roots of an equation.

1. If we can find two quantities, which, being ſubſtituted for the unknown quantity in any equation, give two reſults with contrary ſigns, then will theſe two quantities

be the limits of the value of x, that is, a value of x will always be found between theſe two quantities.

Let $x^m - A x^{m-1} + B x^{m-2} - C x^{m-3} + \&c. + N = 0$; and ſuppoſe that, by ſubſtituting any quantity p, inſtead of x, we have

$$p^m - A p^{m-1} + B p^{m-2} - C p^{m-3} + \&c. + N = R;$$

and by ſubſtituting another quantity, q, for it, we obtain

$$q^m - A q^{m-1} + B q^{m-2} - C q^{m-3} + \&c. N = - S:$$

then, I ſay, that there is at leaſt one real value of x between the limits p and q; that is, x is leſs than the former, and greater than the latter. The truth of the propoſition, however, is better demonſtrated from a partial than from a general example.

Let us, therefore, aſſume the equation

$$x^3 - 13 x^2 + 7 x - 1 = 0;$$

here, if we ſubſtitute $x = 2$, and $x = 20$, we have a reſult in the firſt caſe $= - 31$; and in the ſecond $= + 2939$; and it remains to be ſhewn that there is, at leaſt, one real value of x compriſed between theſe limits. For this purpoſe, the equation may be written

$$x^3 + 7 x - (13 x^2 + 1)$$

which quantity is found to be negative when $x = 2$; but poſitive when $x = 20$. That is, in the firſt caſe, we have

$$(x^3 + 7 x) < (13 x^2 + 1),$$

and in the latter

$$(x^3 + 7 x) > (13 x^2 + 1).$$

Now, it is obvious, that each branch of theſe expreſſions will increaſe as x is augmented, and that they will likewiſe be each diminiſhed as x is diminiſhed. Let us, therefore, conceive x, in the firſt caſe, to be ſucceſſively increaſed by any ſmall quantity, till it arrives at the value of x in the ſecond caſe. Then, ſince $x^3 + 7 x$, which was at firſt leſs than $13 x^2 + 1$, is now become greater than $13 x^2 + 1$, it muſt neceſſarily have paſſed through that ſtate, in which it was neither greater nor leſs; that is, the two branches muſt have paſſed through that ſtate in which they were equal; but when

$$x^3 + 7 x = (13 x^2 + 1),$$

we have alſo

$$x^3 - 13 x^2 + 7 x - 1 = 0;$$

and, conſequently, this value of x is a real root of the equation propoſed.

This reaſoning, though employed only in a particular caſe, is equally applicable to our general equation: for, by putting the poſitive part of the equation $= P$, and the negative $= Q$; alſo, ſuppoſing p to be that value of x which renders the reſult negative, or, which is the ſame, which gives $P < Q$; and q that value which makes $P > Q$, then we may conclude the ſame as above, that P, from being leſs than Q, having paſſed to that ſtate in which it is greater than Q, there muſt neceſſarily be a real value of x, between p and q, which renders $P = Q$; or the propoſed equation $= 0$. We may alſo aſcertain the limits of x between 0, and ſome real quantity, poſitive or negative. For example, in the general equation

$$x^m - A x^{m-1} \pm B x^{m-2} - C x^{m-3} \pm \&c. \pm N = 0,$$

it is obvious, that by taking $x = 0$, the reſult will be negative or poſitive, according as N is affected with the ſign $-$ or $+$. Therefore, if, in the firſt place, we find p ſuch that the reſult is poſitive, and $x = 0$, making it negative, a real value of x muſt lie between the limits p and 0. Again, the above equation may be converted into another, having the ſame roots, only with contrary ſigns, by writing $- y$ for x. And let us ſuppoſe, in the firſt place, that m is even, then the transformed equation will be

$$y^m + A y^{m-1} \pm B y^{m-2} + C y^{m-3} \&c. \pm N = 0;$$

and, conſequently, N will ſtill have, with regard to y^m, the ſame ſign, which, as above, we ſuppoſe to be negative; then, if q be ſuch as will give a poſitive reſult, and $x = 0$ giving a negative, it follows, that a real value of y will be found between the limits q and 0; and, conſequently, in the equation propoſed, a real root is compriſed between the limits $- q$ and 0.

But if the power m be odd, then the transformed equation will be

$$- y^m - A y^{m-1} \mp B y^{m-2} - C y^{m-3} \mp \&c. \pm N = 0,$$

$$\text{or,} \quad y^m + A y^{m-1} \pm B y^{m-2} + C y^{m-3} \pm \&c. \mp N = 0;$$

and, conſequently, y^m and $\mp N$, have not the ſame ſign with regard to each other. If, therefore, now, any value q can be found, ſuch that the reſult may be negative, a root of this equation will be found between the limits q and 0, and, therefore, in the original one between $- q$ and 0.

2. The greateſt poſitive root of an equation is always contained between the limits $S + 1$ and 0; S being the greateſt negative co-efficient that enters into the equation.

In order to prove this, we muſt demonſtrate that in any expreſſion

$$x^m \pm A x^{m-1} \pm B x^{m-2} \pm C x^{m-3} \&c. N.$$

The firſt term may be made to exceed the ſum of all the other terms. Now, it is obvious, in the firſt place, that the caſe which preſents the greateſt difficulty, is that in which all the co-efficients are made negative, and each equal to the greateſt; let, then, S be the greateſt negative co-efficient, it is to be demonſtrated, that ſuch a value of x may be found as will render

$$x^m > S\,(x^{m-1} + x^{m-2} + x^{m-3} + \&c. + 1).$$

Or, ſince the part within the parentheſis is equal to $\frac{x^m - 1}{x - 1}$ we have to ſhew, that we may find x ſuch, that

$$x^m > \frac{S\,(x^m - 1)}{x - 1}, \text{ or } x^m > \frac{S x^m}{x - 1} - \frac{S}{x - 1}.$$

Now, this will be manifeſtly the caſe, if we make

$$x^m = \frac{S x^m}{x - 1}, \text{ or } 1 = \frac{S}{x - 1}, \text{ or } x = S + 1.$$

It is therefore obvious, that this value, ſubſtituted for x in the propoſed equation, will give a poſitive reſult; whereas, $x = 0$ gives a negative reſult: therefore, from what is ſhewn above, a real value of x is found between the limits $S + 1$ and 0. If the foregoing equation be converted into another, with the ſigns of the roots changed, and if R in that equation be the greateſt negative co-efficient, then $- (R + 1)$, and 0, will be the limits alſo of the greateſt negative root.

It follows, immediately from what is ſhewn above, that every equation of even dimenſions, having its laſt term negative, has at leaſt two real roots, the one poſitive and the other negative.

It may alſo be readily demonſtrated, upon ſimilar principles, that every equation of odd dimenſions has at leaſt one real root; a truth which it is difficult to prove in any other manner. See La Croix's Elemens de Algebra, and La Grange's work above quoted.

Limits, in a *Military Senſe*, denote the diſtance which a centry is allowed on his poſt, *viz.* fifty paces to the right, and as many to the left; and though the weather be ever ſo bad, he muſt not get under cover.

Limits *of a Planet*, its greateſt excurſions or diſtances from the ecliptic. See Planet.

LIMITANEI, among the Romans, an appellation given to the ſoldiers who were ſtationed on the frontiers of the empire.

LIMITROTOPHI, among the Romans, the ſame with limitanei.

LIMMA, or Leimma, an interval of the *Greek Muſic*, which is a comma leſs than the ſemitone major, and, retrenched from a tone major, leaves behind the *Apotome;* which ſee.

' The ratio of the limma is 243 to 256, and is generated by beginning at C, and moving by 5ths to B; for then the quantity by which the neighbouring C exceeds B, is preciſely in the ratio which we have eſtabliſhed.

Philolaus, and all the Pythagoreans, made the limma a diatonic interval, which anſwered to our ſemitone major: for, after two conjunctive tones major, there remains only that interval to complete the true 4th, or tetrachord. So that, according to them, the interval from E to F was leſs than that from F to F𝄪. Our chromatic ſcale gives quite the contrary. Rouſſeau.

The abbé Rouſſier has given the muſical etymology of the word leimma, according to Ariſtoxenus. Mem. ſur la Muſ. des Anc. p. 142.

LIMMAT, in *Geography*, a river of Switzerland, which riſes in the Alps, about 11 miles S. of Glarus, aſſuming the name of Lint or Linth, and having paſſed Glarus and joined the Mat, near the lake of Wallenſtadt, takes the name of Limmat, and having traverſed the lake of Zurich, joins the Aar, three miles N. of Baden. The ſtream of this river is very rapid; its water beautifully tranſparent; and its borders, at firſt flat, afterwards gently riſing into hills clothed with paſture and wood, or divided into vineyards, and at laſt becoming quite perpendicular, and fringed to the water's edge with hanging trees. About a mile from Baden, where the Limmat flows with the greateſt rapidity, is a beautiful wooden bridge, 240 feet long, and ſuſpended about 20 feet from the ſurface of the water. It was the laſt work of Grubenman, the ſelf-taught architect, and is far ſuperior in elegance to that of Schaffhauſen.

LIMMEN, a town of Holland; 5 miles S. of Alcmaer.

LIMNÆUS, John, in *Biography*, an eminent German juriſt, was born at Jena in 1592, where his father was profeſſor of mathematics. Having received a good education in the elements of learning, he went to Weimar to purſue his maturer ſtudies, and from thence to the univerſity of his native place, where he remained till the death of his father in 1614, when he removed to Altdorf. In 1618, he engaged himſelf as travelling tutor to two young men of Nuremberg, whom he accompanied to France, England, and Holland. Having finiſhed his engagement with theſe, he took upon himſelf the office of private tutor to ſeveral young perſons of rank, among whom was Albert, margrave of Brandenburg. In proceſs of time, this prince gave him the poſt of chamberlain and member of his privy council. He died in the enjoyment of theſe offices in the year 1663. His works are numerous, and valued for their erudition. The chief are, "Tractatus de Academiis," 4to.; "Notitiæ Regni Galliæ," 2 vols. 4to.; "De jure imperii Romano-Germânici," 5 vols. 4to. Moreri.

LIMNER, corrupted from the French word *enlumineur*, a decorator of books with initial or other pictures. Johnſon.

LIMNIA, in *Botany*. See Claytonia.

LIMNING, (from *enluminer*, Fr. *to adorn books with paintings*). As theſe paintings, or illuminations, as they are called, were always done in water-colours, limning is never properly employed, except it be to deſignate that ſpecies of art, which is now commonly known by the name of miniature-painting, wrought in thoſe colours, and on paper; indeed, it is become almoſt obſolete, though, in the minds of the vulgar, it is ſometimes uſed to ſignify the art of painting generally, and more particularly *Portrait-painting;* which ſee. See alſo the articles Miniature and Water-colours.

LIMNITIS, a word uſed by the ancients to expreſs the concretion of round reeds, or water-plants, by ſome called *adarce:* or ſomewhat analogous to that.

LIMNOPEUCE, in *Botany*, from λιμνη, *a pool* or *lake*, and πευκη, *a pine-tree*, a name given by Vaillant to the *Pinaſtella* of Dillenius, *Hippuris* of Linnæus, in alluſion to its ſpiry ſhape and watery habitation. See Hippuris.

LIMNOPHILA, from λιμνη, *a pool* or *lake*, and φιλεω, *to love*, becauſe it inhabits ſuch places. Brown Prod. Nov. Holl. v. 1. 442. Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Scrophulariæ*, Juſſ.

Eſſ. Ch. Calyx tubular, five-cleft, equal. Corolla funnel-ſhaped; limb in five nearly equal ſegments. Stamens within the tube; anthers cohering in pairs. Stigma dilated, oblique. Capſule of two cells, and two deeply divided valves, the partition inſerted into that edge of the valves which burſts lateſt.

Herbs that inhabit marſhes, with oppoſite deep-cut leaves, moſtly divided into three parts to the baſe, which gives them the appearance of being whorled. Flower-ſtalks axillary, with two bracteas at the top.

The only ſpecies named by the author is

L. *gratioloides*. (Hottonia indica; Linn. Sp. Pl. 208. H. flore ſolitario ex foliorum alis proveniente; Burm. Zeyl. 121. t. 55. f. 1. Tsjudan-tsjera; Rheede Hort. Malab. v. 12. 71. t. 36.)—Gathered in the Tropical part of New Holland by Mr. Brown, who ſuſpects that ſeveral ſpecies are confounded by botaniſts under the above denomination, to be aſcertained by examination of them in a recent ſtate only. It is remarkable that the plant of the *Hortus Malabaricus* is ſaid to grow in a dry ſandy ſoil. See Hottonia.

LIMO. See Citrus.

LIMOCINCTI, among the Romans, a kind of prieſts, who officiated at public ſacrifices, and were dreſſed with a garment called *limus*.

LIMODORUM, in *Botany*, λειμοδωρον, a ſort of paraſitical plant, or rather, as it ſhould ſeem, ſome kind of tare, it being ſaid to choke or ſuffocate the *fænum græcum.* By this latter name we are not perhaps to underſtand literally the fenugreek or *Trigonella,* but may extend it to any other plant cultivated for hay in Greece, as more than one of the leguminous tribe are, or have been. Dodonæus applied this ancient name to the *Orobanche*, or Broom Rape; Cluſius to the *Orchis abortiva* of Linnæus; which at leaſt is what he deſcribed and intended, in his *Stirp. Pannon.* 241, though in his *Hiſtoria* a cut of *Ophrys Nidus-Avis* is, by miſtake, annexed to that deſcription. Linnæus, having referred the plant of Cluſius to the genus *Orchis*, adopted the name in queſtion for a new genus of the ſame natural order; but Swartz, in his excellent treatiſe on this order, having referred the Lin-mean *Limodorum* to his *Cymbidium*, very properly reſtores the name to the original plant of Cluſius, which proves diſtinct in genus from *Orchis*, as Tournefort had done before him. Cluſ. Hiſt. v. 1. 270. Tourn. t. 250. Swartz. Orchid. in Schrad. N. Journ. v. 1. 84. t. 1. f. 4. Ind. Occ. 1519. Willd. Sp. Pl. v. 4. 122.—Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*, Linn. Juſſ. Brown. Prodr. Nov. Holl. v. 1. 309.

Gen. Ch. reformed. *Cal.* Perianth of three, generally ſpreading, equal leaves, rarely reverſed. *Cor.* Petals two, generally ſmaller than the calyx-leaves. Nectary a ſpreading lip, undivided or lobed, concave at the baſe, projecting behind in a ſpur, various in figure and length. *Stam.* Anther an hemiſpherical, ſometimes pointed, terminal, deciduous lid, of two or four cells; maſſes of pollen ſtalked, in pairs. *Piſt.* Germen inferior, oblong, or obovate, nearly upright, furrowed; ſtyle ſemi-cylindrical, often gibbous, concave in front; ſtigma concave or convex, in the front of the ſtyle near the top. *Peric.* Capſule oblong, with three or ſix ribs, with one cell and three valves, opening by clefts between the ribs. *Seeds* numerous, minute, each clothed with a chaffy tunic, inſerted into the downy internal ridges of the valves.

Eſſ. Ch. reformed. Calyx-leaves ſomewhat ſpreading. Lip ſpreading, elongated at the baſe behind into a ſpur. Anther a terminal lid, deciduous.

Dr. Swartz enumerates twenty-one ſpecies, beſides a doubtful one, which is *Rodriguizia* of the Prodr. Fl. Peruv. et Chil. t. 25. Profeſſor Willdenow has twenty-ſeven ſpecies, for though he omits the ſix laſt of Swartz's, having, perhaps, not ſeen Schrader's New Journal, in which, and in its reimpreſſion the *Genera et Species Orchidearum*, only, they are deſcribed; he has added twelve others, which Swartz had only in part indicated as doubtful. All theſe are adopted by Willdenow from books; the ſix whoſe deſcriptions he had not ſeen, were all gathered by Dr. Afzelius at Sierra Leone.

This genus differs from *Cymbidium* in having a ſpur to the nectary, in whoſe cavity the honey is lodged. We have however already mentioned, (ſee CYMBIDIUM,) that this character, though apparently deciſive, is overſet by ſome nondeſcript *Orchideæ*, found by Dr. Buchanan in the Eaſt Indies. Theſe, by every mark, except the abſence or preſence of a ſpur in which they totally differ among themſelves, muſt form one genus, differing in habit from every thing already known; and we have little doubt that a critical examination of them recent, would be the means of detecting ſome over-ruling character, which would ſtamp this genus, independent of all that concerns the ſpur. In that caſe, the latter might ſtill remain a ſufficient diſtinction between *Limodorum* and *Cymbidium*.

Some remarkable ſpecies of *Limodorum* are

L. *Tankervilliæ.* Banks in Ait. Hort. Kew. ed. 1. v. 3. 302. t. 12. Andr. Repoſ. t. 426. Willd. n. 1. (Phaius grandifolius; Loureir. Cochinch. 529.)—Leaves radical, elliptic-lanceolate, pointed, ribbed, plaited. Stalk ſimple, many-flowered. Lip convoluted, with a very ſhort ſpur.—Native of China. It is treated in Europe as a ſtove plant, flowering in the ſpring. We firſt ſaw it at Lady Tankerville's in 1786, and it bloſſomed that year at Haerlem. The great ſize of the whole plant, which much exceeds that of any other of this natural order, whether wild or cultivated in Britain, and the ſplendidly contraſted colours of the *flowers*, render it much admired. The inſide of the calyx and petals is cinnamon-coloured, the outſide of the moſt brilliant poliſhed white; the nectary crimſon, often compared, though certainly inferior in beauty, to the foxglove.

L. *abortivum.* Willd. n. 26. (L. auſtriacum; Tourn. Inſt. 437. Orchis abortiva; Linn. Sp. Pl. 1336. Jacq. Auſtr. t. 193. Epipactis, n. 1288. t. 36. Hall. Helvet. v. 2. 148.)—Leaves none. Stalk with ſeveral tubular ſheaths. Flowers but little ſpreading. Lip wavy. Spur awl-ſhaped, the length of the germen.—Native of ſhady woods in Germany, Italy, the ſouth of France, and ſome parts of Switzerland, but rare even in that country of *Orchideæ*. That it has no right to a place in the Flora of Britain, though admitted by Ray and Hudſon, is now generally allowed. The miſtake aroſe from its being confounded in old books with *Orobanche cærulea*, Engl. Bot. t. 423, as is minutely explained at length in Tr. of Linn. Soc. v. 4. 164—169, and it appears that Lobel's *Orobanche major, e Gramontio luco Monſpellienſium*, Lob. Ic. v. 2. 269. f. 1, which is *Orobanche monſpeliaca floribus oblongis*, Ger. em. 1312, is certainly this *Limodorum*. The *root* conſiſts of two biennial cluſters of thick, cylindrical, divaricated fibres. The *ſtalk* is ſimple and ſolitary, eighteen to twenty-four inches high, clothed with a few cloſe purpliſh ſheaths, and terminating in a cloſe ſpike of rather large *flowers*, variegated with paler and deeper purple.

L. *Epipogium.* Willd. n. 27. (Epipogium; Gmel. Sib. v. 1. 11. t. 2. f. 2. Satyrium Epipogium; Linn. Sp. Pl. 1338. Jacq. Auſtr. t. 84. Epipactis, n. 1289. Hall. Helvet. v. 2. 149.)—Leaves none. Stalk ſheathed. Flowers few, pendulous, reverſed. Lip three-lobed, concave. Spur ovate, aſcending.—This ſingular and rare plant grows in ſome ſhady barren foreſts in Siberia, Germany, and Switzerland. Its pale hue and fleſhy habit, ſo like *Epipactis Nidus-Avis*, indicate its being a paraſitical attendant on the roots of trees. See EPIPACTIS, n. 9; and EPIPOGUM.

Dr. Swartz refers alſo to this ſame genus the *Cypripedium bulboſum*, Linn. Sp. Pl. 1347. Sm. Spicil. t. 11, a moſt curious plant, found in Lapland and Nova Scotia, of which very little is known; but the propriety of this meaſure is in our opinion very doubtful.

LIMODORUM, in *Gardening*, contains plants of the bulbo-tuberous-rooted herbaceous perennial kind, of which the ſpecies commonly cultivated are the tuberous-rooted limodorum (L. tuberoſum); the tall limodorum (L. altum); and the Chineſe limodorum (L. Tankervilliæ.)

Method of Culture.—Theſe plants are increaſed by planting the offsets from the roots in pots of bog-earth, and plunging them, in the firſt ſort, in a mild tan-pit, and in the others, in the tan hot-bed of the ſtove. The proper time of taking them off is when the plants are the moſt deſtitute of leaves.

But the two laſt ſorts ſhould have a loamy mould, and but little water in the winter ſeaſon. And the firſt requires the protection of a good green-houſe in winter, but the two laſt ſhould be kept in the bark-bed of the ſtove.

All theſe plants afford variety in green-houſe and ſtove collections.

LIMOGES, in *Geography*, a city of France, and capital of the department of the Upper Vienne; and before the revolution, the ſee of a biſhop. It is a place of conſiderable trade, and contains about 20,550 inhabitants, and 25,466 in the two cantons, on a territory of 292½ kiliometres, in 11 communes. N. lat. 45° 50′. E. long. 1° 20′.

LIMON, in *Botany*, Tourn. 397, the Lemon. See CITRUS *medica β*.

LIMON, in *Geography*, a ſmall iſland in the W. ſide of the gulf of Bothnia. N. lat. 60° 44′. E. long. 17° 9′.

LIMONA *de la Trou*, a town near the N. coaſt of the iſland of Hiſpaniola; 10 miles S.E. of Cape François.

LIMONE, a town of France, in the department of the

Maritime Alps; S. of Cani.—Alſo, a town of the iſland of Negropont; 20 miles S. of Negropont.

LIMONES, Grande, a town of the iſland of Cuba; 50 miles S. of Havanna.

LIMONEST, a town of France, in the department of the Rhône, and chief place of a canton, in the diſtrict of Lyons. The place contains 750, and the canton 11,089 inhabitants, on a territory of 77½ kiliometres, in 12 communes.

LIMONHE, a town of France, in the department of the Lot, and chief place of a canton, in the diſtrict of Cahors; 13 miles E. of Cahors. The place contains 1175, and the canton 9279 inhabitants, on a territory of 255 kiliometres, in 13 communes.

LIMONIA, in *Botany*, in its preſent application, evidently alludes to *Limon*, the lemon; the genus which is ſo denominated being next akin to *Citrus*, in characters, habit, and ſenſible qualities. The word therefore can have no reference to the λειμωνια of the Greeks, *Limonia* of the Romans, which is a ſpecies of *Anemone*, and derives its name from λειμων, *a meadow*.—Linn. Gen. 213. Schreb. 285. Willd. Sp. Pl. v. 2. 571. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 43. Juſſ. 261. Lamarck Illuſtr. t. 353. Gærtn. t. 58.—Claſs and order, *Decandria Monogynia*. Nat. Ord. *Aurantia*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very ſmall, in from three to five, more or leſs deep, ſegments, permanent. *Cor.* Petals from three to five, oblong, obtuſe, erect, ſpreading at the ſummit. *Stam.* Filaments from ſix to ten, awl-ſhaped, erect, ſhorter than the corolla; anthers linear, erect. *Piſt.* Germen oblong, ſuperior; ſtyle cylindrical, the length of the ſtameas; ſtigma capitate, flat. *Peric.* Berry ovate, or nearly globoſe, of three cells, with membranous partitions. *Seeds* ſolitary, ovate.

Eſſ. Ch. Calyx in from three to five deep ſegments, inferior. Petals three to five. Berry of three cells. Seeds ſolitary.

Three ſpecies of this genus, all tropical ſpinous ſhrubs, and much reſembling orange trees in miniature, were known to Linnæus. Five without ſpines, adopted from Forſter, Lamarck and Retzius, are added by Willdenow. Two more from the Eaſt Indies, deſcribed by Dr. Roxburgh, one with and one without ſpines, are mentioned in Mr. Aiton's new edition.

Examples of the ſpinous ſpecies are

L. *monophylla*. Simple-leaved Thorny Limonia. Linn. Mant. 237. Roxb. Corom. v. 1. 59. t. 83. (Limones pumili zeylanici ſylveſtres; Burm. Zeyl. 143. t. 65. f. 1.) —Leaves ſimple. Spines ſolitary.—Native of the Eaſt Indies, in the extenſive foreſts of the coaſt of Coromandel, where it is called by the natives the Wild Lime. This is a *ſhrub* or ſmall *tree*, with alternate, ſtalked, ovate, entire, obtuſe, evergreen, ſhining *leaves*, full of pellucid dots, as are thoſe of all the reſt, and each accompanied by a ſharp axillary thorn. The *flowers* are white, in axillary cluſters. *Petals* four. *Stamens* ten, united into a firm hemiſpherical cup. *Berry* the ſize of a very ſmall gooſeberry, browniſh, of four cells, thickly coated.—Notwithſtanding the monadelphous ſtamens and ſimple leaves, this ſpecies has too entirely the habit of the reſt to be ſeparated from them.

L. *trifoliata*. Three-leaved Limonia. Linn. Mant. 237. Jacq. Ic. Rar. t. 463. Andr. Repoſ. t. 143.—Leaves ternate. Spines in pairs.—Native of the Eaſt Indies. It makes a pretty appearance in the ſtove, when decorated either with its white bloſſoms, which are three-cleft and hexandrous, or its ſcarlet berries, which are ſweet and pleaſantly acid. The *leaflets* are emarginate, the central one largeſt. *Branches* zigzag and ſlender.—When this ſhrub flowered ſome years ſince at Vienna, it anſwered ſo ill to the character of *Limonia*, in number of parts, that the celebrated Jacquin was near making a new genus of it, which he deſtined to honour an Engliſh botaniſt. There can be no doubt however that it belongs to *Limonia*. "Le petit citron doux" of Sonnerat, Voy. to New Guinea, 102. t. 63, is made a variety of this by Willdenow, who, judging by the figure, not the deſcription, improperly ſays it has no ſpines. The ſeſſile *leaves*, and ſolitary *flowers*, give it a different appearance.

Of the unarmed ſpecies are

L. *pentaphylla*. Five-leaved Limonia. Retz. Obſ. faſc. 5. 24. Roxb. Corom. v. 1. 60. t. 84.—Spines none. Leaves pinnate; leaflets elliptical, entire, two pair with an odd one.—Native of the Eaſt Indies. The *flowers* are ſmall and white, exquiſitely fragrant, in axillary branched cluſters. *Fruit* red, the ſize of a currant. *Stamens* ten, diſtinct, ſpindle-ſhaped.

L. *arborea*. Tree Limonia. Roxb. Corom. v. 1. 60. t. 85.—Spines none. Leaves pinnate; leaflets ſerrated, oblong, two pair with an odd one.—From the ſame country. The *flowers* are very numerous, in branched cluſters, fragrant. *Fruit* ſmall, brown. *Stamens* thread-ſhaped.

Limonia, in *Geography*, an iſland in the Mediterranean, about three miles long, and one broad; ſix miles W. of Rhodes. N. lat. 36° 27′. E. long. 27° 22′. On its eaſtern coaſt is a ſmall haven, defended by a ſhoal, on the margin of which ſtands the only village in the iſland. At ſome diſtance from Limonia is Narki, or Karki, anciently Chalcia, or Chalcis, which ſeems by ſeveral ſhoals that riſe above the waters to have formerly joined with Limonia.

LIMONIUM, in *Botany*, derived, as it appears, from λειμων, *a meadow*, (becauſe the plant occupies, to a great extent, low tracts of land on the ſea-ſhore,) is the old name for ſeveral ſpecies of Sea Lavender. (See Statice.) The ſame name has been alſo applied to the Red Valerian, to the Buck-bean, and even to the *Pyrola rotundifolia*. The latter indeed does grow on low ſandy commons in Holland, and near Yarmouth, but likewiſe in the moſt elevated heathy alpine places; nor, as far as we know, in ſcarcely any intermediate ſtation; for what is ſo named in books is often *P. minor*. The coincidence of alpine and maritime plants, found in no other ſituations, is a curious problem for the vegetable phyſiologiſt.

Limonium-*Gall*, in *Natural Hiſtory*, the name of a ſpecies of gall or vegetable protuberance, ſerving for the lodging of an inſect, affording a very beautiful appearance on the plant, and very common in the eaſtern parts of the world.

This of the limonium is ſingular, in that it is produced from a butterfly egg, and is inhabited by a true caterpillar. The butterfly depoſits her eggs on ſeveral parts of the leaves and ſtalks of this plant, and the young caterpillar, as ſoon as hatched, eats its way through the ſurface; and continuing to eat when within, his depredations occaſion an abundant derivation of juices to the part, by means of which a gall, or protuberance, is formed, which is ſuſtained by a pedicle, and in all reſpects reſembles a fruit. This is of a roundiſh figure, and by degrees grows to the ſize of a nutmeg. It is compoſed of ſeveral coats, or cruſts; the exterior ones are ſoft and ſpungy, but the interior are harder, and more woody than the galls of the oak. As the generality of other caterpillars feed on the ſubſtance of the leaves of trees and plants, this eats only the inſide of its lodgment; and nature ſo readily ſupplies this defect by new matter, that the cavity, in which it is lodged, is never found to be very great.

This ſeems the only known inſtance of a gall formed by a genuine caterpillar, the inhabitants of the willow galls, though uſually eſteemed ſmooth caterpillars, being not ſo, but the worms of a four-winged fly. Reaumur's Hiſt. of Inſects, vol. vi. p. 227.

LIMOSA, in *Ornithology*, the ſcolopax glottis of Linnæus, the name of a long-legged water-bird, common in Italy, and called by ſome *glottis*, and *pluvialis major*. See alſo SCOLOPAX *limoſa*, *fuſca* and *Fedoa*, *Tetanus*, &c. &c. and RECURVIROSTRA *Americana*.

LIMOSA, in *Ichthyology*, a name given by Salvian to the common mackarel, and in his figures to the *thynnus*, or tunny-fiſh, called the *Spaniſh mackarel*. See *Thynnus* SCOMBER.

LIMOSANO, in *Geography*, a town of Naples, in the county of Moliſe; 17 miles N.E. of Moliſe.

LIMOSELLA, in *Botany*, derived from *limus*, mud, from the circumſtance of its growing and thriving in muddy pools and ditches. For the ſame cauſe it has obtained the Engliſh appellation Mudwort.—Linn. Gen. 320. Schreb. 419. Willd. Sp. Pl. v. 3. 341. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 668. Ait. Hort. Kew. 2. 359. Brown Prod. Nov. Holl. 443. Juſſ. 96. Lamarck Illuſtr. t. 535. Gærtn. t. 50.—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Preciæ*, Linn. *Lyſimachiæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, five-cleft, erect, acute, permanent. *Cor.* of one petal, bell-ſhaped, erect, equal, five-cleft, acute; diviſions ſpreading. *Stam.* Filaments four, erect, two of them adhering to the ſame ſide, ſhorter than the corolla; anthers ſimple. *Piſt.* Germen ſuperior, oblong, obtuſe; ſtyle ſimple, as long as the ſtamens, reclining; ſtigma globoſe. *Peric.* Capſule ovate, half covered by the calyx, of one cell and two valves. *Seeds* numerous, oval. *Recept.* ovate, very large.

Eſſ. Ch. Calyx five-cleft. Corolla five-cleft, equal. Stamens approaching each other in pairs. Capſule with one cell, two valves, and many ſeeds.

1. *L. aquatica.* Common Mudwort. Linn. Sp. Pl. 881. Engl. Bot. t. 357. Fl. Dan. t. 69. (Spergula perpuſilla lanceatis foliolis; Loes. Pruſ. 261. t. 81.)—Leaves lanceolate.—Found in muddy pools where water has been ſtanding. Dr. Abbot ſent it to Mr. Sowerby from Bedfordſhire, and Dr. Smith has gathered it on the Denes at Loweſtoft in Suffolk. It flowers in July and Auguſt.—*Root* annual, creeping. *Stems* proſtrate, cylindrical. *Leaves* radical, on long footſtalks, ſmooth, entire, not involute. *Flowers* ſmall, fleſh-coloured. *Calyx* ſomewhat irregular, acute, ſmooth. *Capſule* with a groove along its upper ſide.

2. *L. diandra.* Diandrous Mudwort. Linn. Mant. 252. Kœnig.—Leaves ſomewhat linear.—A native of the Eaſt Indies and the Cape of Good Hope.—The habit of this ſpecies is exactly ſimilar to that of the laſt, but the plant is only about a fourth as large in all its parts, ſo that it may be conſidered as one of the ſmalleſt of all plants. *Stems* creeping, ſhort. *Leaves* radical, linear, ſcarcely widening in the middle, obtuſe. Linnæus complains that on account of the minuteneſs of the *flowers* he could not deſcribe them from a dried ſpecimen, but that the acute diſcoverer of this ſpecies, Kœnig, found them to be diandrous.

3. *L. auſtralis.* New Holland Mudwort. Brown. Prod. Nov. Holl. 443.—Leaves ſpatulate linear.—We know nothing of this ſpecies, but we inſert it, on the authority of Mr. Brown, as a native of New Holland, who juſtly obſerves that all the ſpecies ſtand in need of further inveſtigation.

LIMOURS, in *Geography*, a town of France, in the department of the Seine and Oiſe, and chief place of a canton, in the diſtrict of Verſailles; nine miles S. of Verſailles. The place contains 858, and the canton 7304 inhabitants, on a territory of 147½ kiliometres, in 14 communes.

LIMOUX, a town of France, and principal place of a diſtrict, in the department of the Aude. N. lat. 43° 3'. E. long. 2° 18'. The place contains 5142, and the canton 12,556 inhabitants, on a territory of 240 kiliometres, in 23 communes.

LIMPET, in *Conchyliology*. See PATELLA and CONCHOLOGY.

LIMUS, among the Romans, a garment reaching to the ground, and worn by the prieſts, who on that account were called *limocincti*.

LINACAGAN, in *Geography*, one of the iſlands in the Eaſt Indian ſea, called Calamianes. N. lat. 11° 40'. E. long. 120° 10'.

LINACRE, THOMAS, in *Biography*, an eminent phyſician, and one of the moſt elegant ſcholars of his age, was born at Canterbury about the year 1460. Having completed his ſchool education, under a very eminent maſter, in his native city, he entered at Oxford, and was choſen fellow of All-Souls' college in 1484. His deſire of farther advancement in learning induced him to accompany his former ſchoolmaſter, De Selling, into Italy, whither the latter was ſent on an embaſſy to the court of Rome by Henry VII. De Selling left him at Bologna, with ſtrong recommendations to Angelo Poliziano, who was at that time accounted one of the moſt elegant Latiniſts in Europe; but whom our young ſtudent, by his aſſiduous application, at length excelled in the purity of his ſtyle in that language. At Florence, Linacre had the good fortune to acquire the favour of that munificent patron of literature, Lorenzo de Medicis, who granted him the privilege of attending the ſame preceptors with his own ſons. He knew how to profit by ſuch an opportunity; and under Demetrius Chalcondylas, who had fled from Conſtantinople when it was taken by the Turks, he acquired a perfect knowledge of the Greek language. Thus accompliſhed in claſſical learning, he went to Rome, and ſtudied medicine and natural philoſophy under Hermolaus Barbarus. He applied particularly to the works of Ariſtotle and Galen, and is ſaid to have been the firſt Engliſhman who was well acquainted with thoſe writers in the original Greek. On his return to England, he took the degree of doctor of phyſic at Oxford, and gave lectures on phyſic and taught the Greek language in that univerſity. His reputation ſoon became ſo high, that king Henry VII. called him to court, and entruſted him with the care both of the health and education of his ſon, prince Arthur. He is ſaid alſo to have inſtructed princeſs Catherine in the Italian language. He was made ſucceſſively phyſician to the kings Henry VII., Henry VIII., and Edward VI., and to the princeſs Mary.

In the reign of Henry VIII., indeed, he appears to have ſtood above all rivalſhip at the head of his profeſſion; and he evinced his attachment to its intereſts, as well as to the public good, by various acts; but eſpecially by founding two lectures on phyſic in the univerſity of Oxford, and one in that of Cambridge, and by obtaining the inſtitution of the Royal College of Phyſicians in London. He ſaw with concern, that the practice of medicine was chiefly engroſſed by illiterate monks and empirics, licences being eaſily obtained by improper perſons, when the biſhops were authoriſed to examine and licenſe practitioners in an art of which they could not be competent judges. Through the intereſt of cardinal Wolſey, therefore, Linacre obtained letters patent in 1518 from Henry VIII., conſtituting a corporate body of regularly bred phyſicians in London, in whom was veſted the ſole right of examining and admitting perſons to practiſe within the city, and ſeven miles round it; and alſo of licenſing practitioners throughout the whole kingdom, except ſuch as were graduates of Oxford or Cambridge, who by virtue of their degrees were independent of the college, except within London and its precincts. The college had likewiſe authority given to it to examine preſcriptions and drugs in apothecaries' ſhops. Linacre was the firſt preſident of the new college, and continued in the office during the remaining ſeven years of his life; and, at his death, he bequeathed to the college his houſe in Knight-rider-ſtreet, in which its meetings were held. There is no doubt that this inſtitution greatly contributed to the credit and dignity of the medical profeſſion in the metropolis, and many juſtly celebrated names are enrolled among its members. In proceſs of time, however, its foundation became narrowed, and it fell into the uſual monopolizing ſpirit of a corporation, whilſt its powers to controul the audacity of empirical impoſtors (the principal object of its eſtabliſhment) have ſunk into total diſuſe.

Towards the latter part of his life, in the year 1519, Linacre entered into holy orders; a ſtep to which, it would ſeem, he was principally induced, from a deſire to obtain a ſtudious and eaſy retirement, at a time when he became exceedingly afflicted with that painful diſeaſe, the ſtone, which greatly incapacitated him for buſineſs, and at length put an end to his life. Sir John Cheke relates that, not long before his death, when worn out by ſickneſs and fatigue, he firſt began to read the New Teſtament; and that when he had peruſed the fifth, ſixth, and ſeventh chapters of St. Matthew, he threw the book from him with violence, exclaiming, "either this is not the goſpel, or we are not Chriſtians!" a declaration, if rightly underſtood, equally honourable to the morals he found there inculcated, and ſatirical to thoſe of the age. He died in great agonies from the ſtone, on the 20th of October, 1524, at the age of ſixty-four, and was buried in St. Paul's cathedral, where a monument was afterwards erected to his memory by his admirer and ſucceſſor in fame, Dr. Caius.

In his literary character, Linacre ſtands eminently diſtinguiſhed; inaſmuch as he was one of the firſt, in conjunction with Collet, Lilly, Grocin, and Latimer, who revived, or rather introduced, the learning of the ancients in this iſland. Tranſlations from the Greek authors into Latin were the chief occupations of the literati of thoſe times; and Linacre conferred a benefit on his profeſſion, by tranſlating ſeveral of the moſt valuable pieces of Galen. Theſe were the treatiſes, "De Sanitate tuenda," in ſix books, which was printed at Cambridge in 1517, and dedicated to king Henry VIII.; "De Morbis curandis," in fourteen books, printed at Paris in 1526; three books, "De Temperamentis," and one "De inæquali Temperie," firſt printed at Cambridge in 1521, and inſcribed to pope Leo X.; "De naturalibus Facultatibus," three books, together with one book "De pulſuum Uſu," the firſt time of printing, which is unknown, but they were reprinted by Colinæus in 1528, as well as his poſthumous tranſlation of the four books "De Morborum Symptomatibus." In theſe verſions Linacre exhibited a Latin ſtyle ſo pure and elegant, as ranked him among the fineſt writers of his age: it was laboured, indeed, with that ſolicitude of correctneſs, which beſpoke a Latiniſt formed in the Italian ſchool of that time. His friend Eraſmus deſcribes him as "Vir non exacti tantum, ſed ſeveri judicii;" and Huet, in his learned treatiſe "De claris Interpretatoribus," gives him the praiſe of extraordinary elegance and chaſteneſs of ſtyle, but intimates that he occaſionally ſacrifices fidelity to theſe qualities.

It was, indeed, on his reputation as a philologiſt, that he ſeems chiefly to have valued himſelf. His firſt eſſay was a tranſlation of "Proclus on the Sphere," dedicated to his pupil, prince Arthur; and he alſo wrote a ſmall book of the rudiments of the Latin Grammar, in Engliſh, for the uſe of the princeſs Mary, which was afterwards tranſlated into Latin by the celebrated Buchanan. But the work which appears to have engaged a very large portion of his time, and was univerſally acknowledged to be a work of the moſt profound erudition, was a larger grammatical treatiſe, entitled "De emendata ſtructura Latini Sermonis, libri ſex." This work, which was not printed till after his death, in December 1524, when it appeared with a recommendatory letter from the learned Melancthon, was received with much applauſe by men of erudition, and paſſed through ſeveral editions: it was too complex however, and too profound in metaphyſical diviſions, and in the philoſophy of language, for popular uſe. His friend Eraſmus, indeed, in his "Moriæ Encomium," beſtowed ſome good-natured raillery upon the author, for having tortured himſelf for twenty years by the ſubtleties of grammar, and, after forſaking other more important objects, thought himſelf happy in living long enough to eſtabliſh certain rules for diſtinguiſhing the eight parts of ſpeech.

In his profeſſional character, Linacre acquired univerſal reputation, among his countrymen and contemporaries, for ſkill and practical ability, as well as for his learning; and he was equally the ſubject of applauſe and eſtimation as an upright and humane phyſician, a ſteady and affectionate friend, and a munificent patron of letters. It were ſufficient of itſelf to juſtify this eulogium, to mention that he was the intimate friend of Eraſmus. That great and worthy man frequently takes occaſion to expreſs his affection and eſteem for his character and abilities; and writing to an acquaintance, when ſeized with an illneſs at Paris, he pathetically laments his abſence from Linacre, from whoſe ſkill and kindneſs he might receive equal relief. The following epitaph, written by Caius, will be acceptable to the learned reader from the elegance of its compoſition.

"Thomas Lynacrus, Regis Henrici VIII. medicus; vir et Græcè et Latinè, atque in re medica longe eruditiſſimus. Multos ætate ſua languentes, et qui jam animam deſponderant, vitæ reſtituit. Multa *Galeni* opera in Latinam linguam, mira et ſingulari facundia, vertit. Egregium opus de emendata ſtructura Latini ſermonis, amicorum rogatu, paulo aute mortem edidit. Medicinæ ſtudioſis *Oxoniæ* publicas lectiones duas, *Cantabrigiæ* unam, in perpetuum ſtabilivit. In hac urbe Collegium Medicorum fieri ſua induſtria curavit, cujus et Præſidens proximus electus eſt. Fraudes doloſque mirè peroſus; fidus amicis; omnibus juxta charus: aliquot annos antequam obierat Preſbyter factus; plenus annis, ex hac vita migravit, multum deſideratus, anno 1524, die 21 Octobris. Vivit poſt funera virtus. Thomæ Linacro clariſſimo Medico, Johannes Caius poſuit, anno 1557. See Aikin's Biog. Memoirs of Med. Freind's Hiſt. of Phyſic. Gen. Biog.

LINAGROSTIS, in *Botany*, from λινον, *thread*, and αγρωστις, *graſs*, the old name of the Cotton-graſs. See ERIOPHORUM.

LINARES, in *Geography*, a town of Spain, in the kingdom of Jaen, ſix leagues from the Sierra Morena; only remarkable for a fountain with many jets, and the remains of a Roman aqueduct, by which water was conveyed to the ancient Caſtelo, now Cazlona. In the neigbourhood are very rich lead mines, and one of a ſemi-metal, with which the emerald tint is given to porcelain. Two leagues from this town there is a ſilver mine, famous in the time of the Carthaginians, which belonged to the beautiful Himilca, wife of Aſdrubal. The Romans alſo worked this mine. It has a ſhaft 2000 feet deep, into which numerous galleries open. It was long neglected; but re-opened in the 17th century, when a vein of ſilver was found five feet broad: however, it has ſince been diſregarded. It belongs to the town of Bäeza.

LINARIA, in *Botany*, ſo called from having the habit and foliage of *Linum*, or Flax, is the Toad-flax. (See ANTIRRHINUM.) The French botaniſts are partial to the name, though certainly none of the beſt; and as they divide the genus, retain *Antirrhinum* for ſuch ſpecies only as have no ſpur.

LINARIA, in *Ornithology*. See FRINGILLA and LINNET.

LINARYD, in *Geography*, a town of Sweden, in the province of Smaland; 11 miles S.S.E. of Wexio.

LINATO, a town of Italy, in the department of the Olona, on the Lambro; 5 miles S.E. of Milan.

LINBO, a ſmall iſland in the Adriatic. N. lat. 44° 37′. E. long. 14° 57′.

LINCH-CLOUT, in *Artillery*, the flat iron under the ends of the arms of an axle-tree, to ſtrengthen them, and diminiſh the friction of the wheels. See CLOUTS.

LINCH-*Pin*, in *Rural Economy*, the ſmall pin, in carts or other carriages, that is put upon the end of the axle-trees, to confine the wheels on them in a ſteady manner. See LINSPINS.

LINCHANCHIA, in *Geography*, a town of Mexico, in the province of Yucatan; 25 miles N. of Merida.

LINCKIA, in *Botany*, ſo called by Micheli, in honour of John Henry Linck, an apothecary at Leipſic, fellow of the Royal Society of London, who died in 1734, at the age of 60. He wrote an account of the coffee-tree, from one which flowered in a garden near his reſidence, in 1724, and his treatiſe may be ſeen in the *Ephemerides* of the Acad. Naturæ Curioſorum, v. 1. 204. He is alſo the author of a ſplendid work in folio, on the ſpecies of Star-fiſh, *Aſterias*. The plant to which Micheli has given his name, ſee Mich. Gen. 126. t. 67, is *Tremella Noſtoc* of Linnæus. See TREMELLA.

LINCOLN, an ancient city in the county of that name, England, and a place of conſiderable importance in the eccleſiaſtical and military annals of the kingdom, is ſingularly ſituated on the top and ſide of an eminence, which ſlopes with a ſteep deſcent to the ſouth, where the river Witham runs at its baſe. A large portion of the city, or rather ſuburbs, extends, in a long ſtreet, from the foot of the hill to the ſouth. On the northern ſide of it, without the walls, is another ſuburb, called Newport, ſuppoſed to have been an outwork of the Roman ſtation. Camden, and ſome other antiquaries, ſtate, that this place was occupied as a ſtation, or ſtrong hold, by the Britons, anterior to the Roman colonization of the iſland; and that then it bore the name of "Lindcoit, from the woods (for which ſome copies have, corruptly, Lintcoit)." By Ptolemy and Antoninus the name of the place is written Lindum; and, from having the privilege of a colony, it was called Lindum colonia. As a military ſtation, occupied by a colony of Romans, it muſt have been a place of ſome extent and conſequence. This is evident from the veſtiges that remain, and from the various diſcoveries that have been made at different periods. The form of the fortified ſtation was that of a parallelogram, divided into four equal parts by two ſtreets, which croſſed it at right angles. At the extremities of theſe were four fortified gates, nearly facing the four cardinal points. The whole was encompaſſed by an embattled wall, which, on three ſides, was flanked by a deep ditch, but on the ſouth ſide the ſteepneſs of the hill rendered a foſs unneceſſary. The area, thus incloſed, was about 1300 feet in length by 1200 in breadth, and is eſtimated to have contained thirty-eight acres. The walls have been levelled with the ground; and three of the gates have been long ſince demoliſhed. The remaining gate, to the north, which is called Newport gate, is deſcribed by Dr. Stukeley as "the nobleſt remnant of this ſort in Britain, as far as I know;" and he expreſſes much ſurpriſe, that it had not "been taken notice of" before his time. The great or central gateway has a ſemi-circular arch, ſixteen feet in diameter, formed with twenty-ſix large ſtones, apparently without mortar. The height is twenty-two feet and a half, of which eleven are buried beneath the ground. On each ſide of the arch are ſeven courſes of horizontal ſtones, called ſpringers, ſome of which are from ſix to ſeven feet in length. On each ſide of the arch are two ſmall lateral doorways or poſterns. A maſs of the old Roman wall is ſtill to be ſeen eaſtward of this gate; and to the weſt is another large maſs, called the mint-wall, which was about ſixteen feet high and forty feet long, and had ſcaffold-holes and marks of arches. Mr. Gough ſuppoſed this to be part of a Roman granary. Southward of the ſtation above deſcribed were other Roman works, which extended from the brow to the bottom of the hill. It appears that a fortified wall, with towers at the corners, continued from the top to the bottom of the hill, where it turned at right angles by the ſide of the river. Theſe fortifications underwent ſeveral alterations and additions, during the various wars to which the place was ſubjected. Hence it is very difficult, if not wholly impoſſible, to define what is really of Roman origin, or of Saxon or Norman workmanſhip. It is equally perplexing to aſcertain the time of eſtabliſhing the firſt colony here forming the ſtation, building the walls, or extending the city. Various coins and other remains of antiquity have been diſcovered here. In 1739, three ſtone coffins were found at the ſouth-weſt corner of the cloſe, near the Chequer gate. Beneath theſe was a teſſellated pavement, and under that a Roman hypocauſt. A ſimilar diſcovery was made in 1782. In the tenth volume of the Archæologia is a deſcription of an ancient place of ſepulture, diſcovered in an open field, half a mile from the eaſt gate of the ancient Lindum. In 1790 was found, about three or four feet below the ſurface, a very curious ſepulchral monument, evidently Roman, and of ſome perſon of high rank. Many fragments of antiquity were preſerved by the Rev. Dr. Gordon, the precentor of the cathedral, who gives an account of ſeveral earthen and glaſs urns, which were diſcovered in the ſame field, ſome of which were of ſingular ſhape. He alſo deſcribes a room, twenty feet by ſixteen, which was diſcovered in a quarry. The ſame field having been broken up for the purpoſes of quarrying, ſeveral ſtone coffins of various ſhapes have at different times been diſcovered in the looſe ground, which covers a ſubſtratum of rock. From theſe, and from other circumſtances, it is highly probable that this was a Roman burial-ground.

Soon after the Romans quitted the iſland, Lincoln, in common with other places of conſequence, ſhared in the general calamities which enſued by the incurſions of the Picts, Saxons, and Danes. At what period the Saxons firſt poſſeſſed themſelves of this city does not appear in hiſtory: but early in the ſixth century we find Arthur, king of Britain, obtaining great advantages over the combined forces of the two Saxon chiefs, Colgern and Cerdic, and compelling them to relinquiſh the ſiege of Lincoln. In thoſe ſtruggles the old town was nearly deſtroyed, and, as Leland ſuppoſes, “ new Lincoln was made out of a piece of old Lincoln.” The Saxons, for their better ſecurity, fortified the ſouthern part of the hill with ditches and ramparts, walled the town, and erected gates. At the time of the Norman conqueſt, Lincoln appears to have been one of the richeſt and moſt populous cities in England: and of great importance as an emporium of trade and commerce. The Domeſday Survey mentions 1070 manſions, 900 burgeſſes, and 12 lagemen, having ſac and ſoke. On the acceſſion of the Conqueror to the throne, he ordered four ſtrong caſtles to be built; of which one was to be at Lincoln. In conſequence of this, a large and ſtrong caſtle was erected on the ridge of the hill, on which this city was ſituated. The building was 644 yards in circumference, and occupied the ſpace on which it is aſſerted that 166 houſes had ſtood; 74 more were at the ſame time demoliſhed without the limits, that the whole might be inſulated. In the reign of Henry I. a navigable canal was made, or enlarged, from the river Witham at Lincoln to the Trent near Torkſey; and was probably the firſt canal of the ſort ever made in England. This was about ſeven miles in length, and is at preſent called the Foſs-dyke. By this a communication was formed with the Trent, and down that by the Humber to the ſea. Being thus acceſſible for foreign veſſels, and having alſo the advantage of an inland navigation, the city became populous and wealthy; and, according to Alexander Necham, a poet of that age, “ Lincoln was now ſtored with good things, and became the ſupport of the neighbouring country.” At this period, it appears to have poſſeſſed a large ſhare of the import and export trade of the kingdom. When, in the year 1140, the empreſs Maud came to England to aſſert her title to the crown, ſhe took up her reſidence at Lincoln, as a place of ſafety, and conveniently ſituated for communication with her friends. Stephen hearing of it marched quickly thither, cloſely beſieged the city, and took it: but the empreſs had eſcaped. The king, having poſſeſſed himſelf of the city, appeaſed the tumults of the neighbourhood, and finding the country quiet, left a garriſon, and proceeded to his army, acting in other parts of the kingdom. During the conteſt between the empreſs and Stephen, Lincoln acquired great notoriety; and thence obtained a degree of conſequence in the eſtimation of future monarchs. After Henry II. had been crowned in London, he was afterwards, according to Speed, crowned at Lincoln in the year 1155. We find this city and its caſtle materially concerned in the contentions between king John and the aſſociated barons. The caſtle and bail of Lincoln appear to have continued in the occupation of the crown till the time of Edward I., when Henry de Lacy died ſeiſed of them, and they paſſed, with other parts of his inheritance, to the earl of Lincoln, and ſo became annexed to the duchy of Lancaſter. John of Gaunt, duke of that palatinate, greatly improved the caſtle, and made it his ſummer reſidence; having, according to a local tradition, built himſelf a winter palace below the hill, in the ſouthern ſuburbs. Several parliaments were held at Lincoln in the reigns of Edward I. II. and III. In the year 1348, the contracted ſpirit of monopoly ſo far prevailed here, againſt the acts of parliament paſſed in the years 1335 and 1337, and the king's reſolutions to foſter the woollen manufactures, that the weavers of Lincoln obtained a grant from Edward III., of what they conſidered and called their *liberties*. By this charter they were inveſted with the power of depriving any weaver not of their guild, of the privilege of working at his trade within twelve leagues of the city. This and other ſimilar monopolies were aboliſhed in 1351, by an act called the *Statute of Cloths*. In the following year, the ſtaple of wool was removed from Flanders to England; and Lincoln was one of the ſtaple towns appointed on that occaſion. It was alſo made a ſtaple for leather, lead, and various other articles. This proved highly beneficial to the place, for it thereby recovered from the loſſes it had ſuſtained by military ravages, and was ſoon reſtored to a flouriſhing condition. At the commencement of hoſtilities between Charles I. and his parliament, the king came to Lincoln, and convened the nobility and freeholders of the county.

The dioceſe of Lincoln, after the ſee was removed from Sidnaceſter, ſoon acquired a vaſt accumulation of territorial juriſdiction and wealth. It included ſo many counties, that it was deſcribed as ready to ſink under the incumbent weight of its own greatneſs; and though Henry II. took out of it the dioceſe of Ely, and Henry VIII. thoſe of Peterborough and Oxford, it is ſtill conſidered the largeſt in England. As the juriſdiction was great, ſo, prior to the reformation, the revenues were proportionably abundant. Except the two archbiſhoprics, and thoſe termed the principality biſhoprics, Wincheſter, Durham, and Ely, no ſee was ſo well endowed, which was the reaſon that there is no record, prior to the time of Elizabeth, of any biſhop of this ſee having been tranſlated to another, except Wincheſter; though ſince that time, Willis obſerves, “ no leſs than ten out of ſeventeen have left this for more valuable ones.” Nor was it leſs remarkable for the number of epiſcopal palaces within the dioceſe. Previous to the year 1547, it had eight. In this county, Lincoln, Sleaford, and Nettleham; in Rutlandſhire, Ledington; in Huntingdonſhire, Buckden, the uſual reſidence of the biſhops; in Buckinghamſhire, Woburn and Finghurſt; in Oxfordſhire, Banbury Caſtle: there were alſo two others at Newark in Nottinghamſhire; and Lincoln Place, Chancery Lane, London. All theſe, except that at Lincoln, with about thirty manors, were given up, in the firſt year of Edward VI., by Holbech, the firſt married biſhop; who, in order to gratify the wiſhes of ſome courtiers, and to raiſe his own family, exchanged almoſt every ſpecies of landed property annexed to the ſee for impropriations; ſo that now only four manors remain of the ancient demeſnes. The preſent revenues, therefore, principally ariſe from rectorial property or tythes.

The cathedral is not only the moſt prominent object of this city, but is the moſt intereſting as a ſubject of hiſtory, antiquity, and art. This magnificent ſtructure, from its ſituation on the ſummit of a hill, and from the flat ſtate of the country to the ſouth-eaſt and ſouth-weſt, may be ſeen at the diſtance of twenty miles. Raiſed at a vaſt expence, by the munificence of ſeveral prelates, it diſcovers, in many parts, ſingular ſkill and beauty, particularly in its weſtern front, which muſt attract the attention of every traveller. The ſee being tranſlated from Dorcheſter to Lincoln in 1088, St. Remigius de Feſcamp, the firſt biſhop, founded a cathedral church, which was ſo far advanced in the courſe of four years as to be ready for conſecration. All the biſhops of England were ſummoned to attend on that occaſion. Remigius died two days before the intended ſolemnity. His ſucceſſor, Robert Bloet, finiſhed the cathedral, dedicated it to the Virgin Mary, and greatly enriched it. In his time, the biſhopric of Ely was taken out, and made independent of that of Lincoln. The cathedral, having been deſtroyed by fire in 1124, was rebuilt by Alexander de Blois, then biſhop, who arched the new fabric with ſtone, to prevent a recurrence of a ſimilar accident; and greatly increaſed the ſize and augmented the ornaments of it, ſo as to render it the moſt magnificent ſacred edifice in his time.

Biſhop Hugh Burgundus enlarged it by the erection of what is now called the New Work. He alſo built the chapter houſe. This prelate died in 1200. Two kings (John of England and William of Scotland) aſſiſted to carry his body to the cathedral, where it was enſhrined in ſilver, according to Stukeley; but Sanderſon ſays the ſhrine was of beaten gold. Biſhop Gynewell added to the cathedral the chapel of St. Mary Magdalen. Biſhop Fleming built a chapel on the north ſide, in which he was buried: on his monument is his figure in free-ſtone, pontifically habited. Biſhop Alnwick was a conſiderable benefactor to the cathedral, and built the ſtately porch at the great ſouth door. Biſhops Ruſſell and Longland built two chapels: to both theſe prelates are altar-tombs, though the latter was interred at Eton.

The cathedral church conſiſts of a nave, with its aiſles; a tranſept at the weſt end; and two other tranſepts, one near the centre, and the other towards the eaſtern end; alſo, a choir and chancel, with their aiſles, of correſponding height and width with the nave and aiſles. The great tranſept has a nave towards the eaſt: attached to the weſtern ſide of this tranſept is a gallilee, or grand porch; and on the ſouthern ſide of the eaſtern aiſle are two oratories, or private chapels; while the northern ſide has one of nearly ſimilar ſhape and character. Branching from the northern ſide are the cloiſters, which communicate with the chapter-houſe. The church is ornamented with three towers; one at the centre, and two at the weſtern end: theſe are lofty, and are decorated with varied tracery, pillars, pilaſters, windows, &c. The dimenſions of the whole ſtructure, according to the accurate meaſurements of Mr. T. Eſpin of Louth, are as follow: the height of the two weſtern towers 180 feet. Previous to the year 1808, each of theſe was ſurmounted by a central ſpire 101 feet high. The great tower in the centre of the church, from the top of the corner pinnacle to the ground, is 300 feet; its width 53 feet. Exterior length of the church, with its buttreſſes, 524 feet; interior length, 482 feet; width of weſtern front, 174 feet; exterior length of great tranſept, 250 feet; interior, 222; width, 66; the leſſer or eaſtern tranſept 170 feet in length, 44 in width, including the ſide chapels; width of the cathedral, 80 feet; height of the vaulting of the nave, 80 feet. The chapter-houſe is a decagon, and meaſures, interior diameter, 60 feet 6 inches. The cloiſters meaſure 118 feet on the north and ſouth ſides, and 91 on the eaſtern and weſtern ſides. The grand weſtern front, wherein the greateſt variety of ſtyles prevails, is certainly the workmanſhip of three, if not more, diſtinct and diſtant eras. This portion of the fabric conſiſts of a large ſquare-ſhaped façade; the whole of which is decorated with door-ways, windows, arcades, niches, &c. It has a pediment in the centre, and two octangular ſtair-caſe turrets at the extreme angles, ſurmounted by plain ſpire-ſhaped pinnacles. The upper tranſept and the choir appear the next in point of date. Theſe are in the ſharp-pointed ſtyle; and their architecture is very irregular, having pillars with detached ſhafts of Purbeck marble, in different forms, but all very light: thoſe on the ſides of the choir have been ſtrengthened. The vaulting is generally ſimple; the ribs of a few groins only have a filleted moulding. A double row of arches or arcades, one placed before the other, is continued round the inſide of the aiſles, beneath the lower tier of windows. The windows, which are lofty and narrow, are placed two or three together; the greater buttreſſes in front are ornamented in a ſingular manner with detached ſhafts, terminating in rich foliage. This part of the fabric was probably built by biſhop St. Hugh. The great tranſept, the gallilee porch, and the veſtry, are nearly of the ſame, but in a later ſtyle. The veſtry is vaulted, the groining having ſtrong ribs; and beneath it is a crypt with groins, converging into pointed arches. The nave and central tower were next rebuilt, probably begun by biſhop Hugh de Welles, as the ſtyle of their architecture is that of the latter part of the reign of John, or the beginning of Henry III. Part of the great tower was erected by biſhop Groſthead, who finiſhed the additions which had been made to the old weſt front. The part extending from the ſmaller tranſept to the eaſt end appears to have been built by biſhops Graveſend, Sutton, and D'Alderby, about the concluſion of the thirteenth, or commencement of the fourteenth century. The latter prelate built the upper ſtory of the rood tower, and added a lofty ſpire, which was conſtructed of timber, and covered with lead. This was blown down in a violent ſtorm in the year 1547; and the damages then ſuſtained were not wholly repaired till 1775. That nothing might be wanting to render this church as ſplendid in its furniture as it was elegant in its workmanſhip, it received the moſt laviſh donations. So ſumptuouſly was it ſupplied with rich ſhrines, jewels, &c. that, Dugdale informs us, Henry VIII. took away 2621 ounces of gold, and 4285 ounces of ſilver, beſides precious ſtones of great value. This cathedral had formerly a great number of coſtly ſepultures and monumental records: of many, not a veſtige remains; nor are the places known where they ſtood. At the Reformation, what the ravages of time had left, the zealots pulled down or defaced; ſo that, at the cloſe of the year 1548, there was ſcarcely a perfect tomb remaining. Among the illuſtrious perſons who were buried here, and had monuments erected to their memory, were Catherine Swinford, wife of John of Gaunt, duke of Lancaſter; Joan, counteſs of Weſtmoreland, their daughter; and Bartholomew, lord Burgherſh, brother to the biſhop of that name. Many of the biſhops were interred here.

On the north ſide of, and connected with, the cathedral are the cloiſters, of which only three ſides remain in the original ſtate. Attached to the eaſtern ſide is the chapter-houſe, a lofty elegant ſtructure. It forms a decagon, the groined roof of which is ſupported by an umbilical pillar, conſiſting of a circular ſhaft, with ten ſmall fluted columns attached to it; having a band in the centre, with foliated capitals. One of the ten ſides forms the entrance: in the other ſides are nine windows, having pointed arches with two lights each. Over the north ſide of the cloiſters is the library, which contains a large collection of books, and ſome curious ſpecimens of Roman antiquities. It was built by dean Honeywood.

Beſides monaſteries, nunneries, and other edifices for pious uſes, Lincoln had formerly more than fifty churches. Eleven only, excluſive of the cathedral, now remain; and ſcarcely any of them merit a particular deſcription. Thoſe moſt worthy of notice are, St. Bennet's, St. Mary de Wigford's, and St. Peter's at Gowts: theſe have lofty ſquare towers in the Norman ſtyle. St. Peter's is a very ancient ſtructure, and appears to have been the chapel of ſome religious houſe, of which the remains are extant. The places of worſhip for the different denominations of Diſſenters, are, one for Roman Catholics, one for Independent Baptiſts, one for Preſbyterians, and one for Methodiſts.

The number of pariſhes within the city is twelve, which, with the four townſhips within its juriſdiction, make ſixteen. Theſe, according to the government ſurvey in the year 1800, contained 1574 houſes, which were inhabited by 7398 perſons. Many of the houſes are old, but there are ſome very good buildings, both upon and below the hill. The city has of late been conſiderably improved, by making a new road, paving the footways, and erecting a new market place.

Lincoln has an extenſive trade in corn and wool, of which great quantities are exported into Yorkſhire, by veſſels which obtain a back freightage of coals and other neceſſary articles for the uſe of the interior. This city is a county of itſelf, having ſubject to it four townſhips in the vicinity, Bracebridge, Canwick, Branſton, and Waddington, called the "Liberty of Lincoln." This privilege was conferred in the third year of George I.; and in official acts it is denominated, "The City and County of the City of Lincoln." Its viſcountial juriſdiction extends twenty miles round; a privilege unequalled by that of any city in the kingdom. In the 26th year of Edward I. A. D. 1298, Willielmus Diſney and Johannes Marmion were ſummoned to parliament as its firſt repreſentatives. In the hiſtory of the boroughs of Great Britain, it is ſaid, "This city had ſummons, with London and York, to ſend members to parliament, the forty-ninth of Henry III." The right of election is conſidered to be in the freemen, and the number of voters is about eleven hundred. The political influence, though by no means abſolute, is poſſeſſed by lord Delaval, who has a ſeat at Doddington, in the neighbourhood. The civil government of Lincoln is veſted in a corporation, conſiſting of a mayor, twelve aldermen, two ſheriffs, twenty-eight common-councilmen, and four chamberlains; with a recorder, deputy recorder, ſteward of the courts of borough-mote, a town-clerk, four coroners, four ſerjeants of the key, or bailiffs, and other inferior officers. The city was incorporated ſo early as the ſeventh year of Edward II.; Henry Belt being then the firſt mayor. Leland, in his deſcription of Lincoln, enumerates five "Gates in the waulles of the citie," and obſerves, "It is eaſy to be perceived, that the towne of Lincoln hath been notably builded at three tymes."

Of the caſtle, built by the Conqueror, little now remains; and the area is occupied by buildings appropriated to uſes of the municipal power. The few remaining veſtiges convey the ſame idea of original Norman architecture as that of York, erected nearly at the ſame period. The keep was not included, but ſtood half without and half within the caſtle wall, which aſcended up the ſlopes of the hill, and joined the great tower. This being ſituated on a high artificial mount, it was equally inacceſſible from within or without the caſtle area. It was nearly round, and covered the ſummit of the mount. The walls are above ſeven feet in thickneſs. In a corner of the area is a curious ſmall building, appearing on the outſide like a tower, called Cob's-hall; which Mr. King thinks was originally uſed as a chapel.

Few places in the kingdom exhibit ſo many ancient remains as Lincoln. Saxon, Norman, and pointed arches; and door-ways with turrets, walls, mullions of windows, and other fragments of old dilapidated buildings, appear in every direction. Its numerous churches and religious houſes, the veſtiges of which occaſionally meet the eye of the enquiring traveller, are highly intereſting to the antiquary, as tending to illuſtrate the progreſs of the arts, and the hiſtory of paſt ages. The Mint-wall, mentioned by Mr. Gough, is ſtill remaining, and forms part of the incloſure of a garden.

Checquer gate, at the weſt end of the cathedral, had two gate-houſes; the weſtern one has been recently taken down; the remaining one, to the eaſt, has three gateways, and two turrets between them. In Eaſtgate-ſtreet are two very ancient gateways, one of which is nearly entire. At the bottom of the town, near Brayford water, are remains of a fort, called Lucy-tower. In the minſter yard is a large gateway, with grooves for a portcullis. A large oblong building, in Broadgate-ſtreet, was appropriated to the Grey friars, and ſtill diſplays much of its ancient architecture: part of this edifice is now uſed as a free-ſchool, and the other part as a library. The deanery-houſe was founded by dean, afterwards biſhop, Graveſend, in 1254. The vicar's college, called the Old Vicars, formed a quadrangle, of which there remain only four good houſes, inhabited by the vicars. The biſhop's palace, on the ſouth ſide of the hill, which, from being ſituated near the ſummit, Leland deſcribed as "hanging in declivio," was built by biſhop Cheſney, to whom the ſcite was granted by king Henry II. It was enlarged by ſucceeding prelates, and was ſcarcely exceeded in grandeur by any of our ancient caſtles. Adjoining to St. Andrew's church-yard formerly ſtood the palace of the celebrated John of Gaunt. Oppoſite to this houſe is a large building, called John of Gaunt's ſtables. It was a large ſtructure, in the Norman ſtyle, and formerly conſiſted of a quandrangle, encloſing a ſpacious area; of which only the north and weſt fronts remain. The Jew's houſe, on the ſide of the hill, is an object of great curioſity: it is ſingularly ornamented in front, and ſome of its mouldings are ſimilar to thoſe round the weſt doors of the cathedral; in the centre of the front is a ſemicircular arched door-way, with a projecting pilaſter. This houſe was poſſeſſed by Belaſet de Wallingford, a Jeweſs, who was hanged for clipping in the 18th of Edward I. The Stone-bow, a large tower-gateway, croſſing the High-ſtreet, is ſaid to have been erected in the reign of Richard II.; but the ſtyle indicates a later date. The High-bridge, over the main ſtream of the Witham, conſiſting of one arch, is conſidered to be at leaſt five hundred years old. Formerly here were two grammar ſchools, one in the cloſe, the other in the city: they were united in 1583. The principal modern buildings are, the market houſe, erected 1736; the blue-coat-ſchool, on the plan of Chriſt's-hoſpital, London; the county hoſpital; the county gaol, conſtructed on the plan of Mr. Howard for ſolitary confinement; two aſſembly rooms, and a ſmall theatre.

Among the diſtinguiſhed natives of Lincoln was the late Dr. Willis, celebrated for his treatment of inſanity, who died at an advanced age December 1807. Beauties of England, vol. ix. The Hiſtory of Lincoln, 12mo. 1810.

Lincoln, a maritime county of America, in the ſtate of Maine, bounded N. by Kennebeck county, S. by the ocean, E. by Hancock county, and W. by that of Cumberland. The ſea-coaſt extends from that part of Penobſcot bay, oppoſite to Deer iſland eaſtward, to Cape Small-point weſtward. The ſea-coaſt of the counties of Cumberland and Lincoln is 100 miles in extent, meaſured in a ſtraight line, but ſaid to be above 200 by the courſe of the waters. It abounds with ſafe and commodious harbours; and the whole ſhore is covered by a line of iſlands, among which veſſels may generally anchor in ſafety. Acroſs the country there is a water communication by lakes, ponds, and rivers, from the weſtern to the eaſtern bounds; ſo that the productions of the country may be conveyed to the different ſea-ports. The chief towns are Wiſcaſſet, Waldoborough, and Warren.—Alſo, a county of Upper Canada, divided into four ridings and 20 townſhips, containing about 6000 inhabitants, and furniſhing five battalions of militia. It is ſaid that 19 covered waggons brought families to ſettle in the vicinity of the county of Lincoln, in June 1799.—Alſo, a county of Morgan diſtrict, North Carolina, containing 12,568 inhabitants, of whom 1479 are ſlaves. In this county are mineral ſprings and mines of iron. The manufacture of iron is carried on in this county. The chief town is Lincolntown.—Alſo, a county of Georgia, formed in 1796, containing ſeven townſhips, and 4766 inhabitants, including 1433 ſlaves.—Alſo, a county of Kentucky, containing 8555 inhabitants, of whom 1750 were ſlaves. The road from Danville on Kentucky river paſſes through ſouth-weſterly, and over Cumberland mountain to Virginia.—Alſo, a town in Mercer county, Kentucky, on the road from Danville to Virginia; 12 miles S.E. of Danville.—Alſo, a townſhip in Grafton county, New Hampſhire, incorporated in 1764, and containing 41 inhabitants.—Alſo, a townſhip in the N.E. part of Addiſon county, Vermont, containing 97 inhabitants.—Alſo, a townſhip in Middleſex county, Maſſachuſetts, incorporated in 1754, and containing 756 inhabitants; 16 miles N.W. of Boſton.

LINCOLNSHIRE, a maritime county of England, is bounded on the N. by the river Humber, which ſeparates it from Yorkſhire; on the E. by the German ocean; on the S. by Cambridgeſhire and Northamptonſhire; and on the W. by the counties of Rutland, Leiceſter, Nottingham, and York. It is in length 77 miles, and about 48 in breadth; and contained, according to the return made to parliament in 1800, 42,489 houſes, inhabited by 208,557 perſons, *viz.* 102,445 males, and 106,112 females: 24,263 were ſtated to be employed in trade and manufacture; and 60,584 in agriculture. By a return to the houſe of lords in 1805, the area of this county is ſtated to be 2787 ſquare ſtatute miles, equal to 1,783,680 ſtatute acres; the number of inhabitants on each ſquare mile 75; and the total number of perſons 209,025. The total amount of the money raiſed by the poor's rate in 1803 was 145,848*l.* at the rate of 3*s.* 7*d.* in the pound; and the groſs amount of the aſſeſſment under the property tax of 1806 was 2,704,736*l.* The average of the deaths for ten years appears to be as 1 to 49½ of the population. Mr. Stone, in his view of the agriculture of this county, eſtimates the number of acres at 1,893,100; of which he ſuppoſes there may be 473,000 acres of incloſed, marſh, and fen lands, 200,000 of commons, waſtes, and unembanked ſalt marſhes, 268,000 of common fields, 25,000 of woodlands, and 927,120 of incloſed upland. Mr. Arthur Young ſtates the area of this county at 2888 ſquare miles, or 1,848,320 acres; of which he ſays, the wolds contain, 234,880; the heath 118,400; lowland 776,960; and miſcellaneous ſoils 718,080.

That part of Britain which is now called Lincolnſhire, was, anterior to the Roman conqueſt, poſſeſſed by a claſs of Britons known by the name of Coritani. During the Roman dominion, this diſtrict was included within the province of Britannia prima; and was interſected by different roads, occupied by military ſtations, and ſome of its natural inconveniences removed by Roman ſcience and induſtry. The principal roads were the Britiſh Ermin-ſtreet, afterwards adopted by the Romans, and the Foſs-way. A great work of this county, generally attributed to the Romans, is the Car-dyke, a large canal or drain, which extends from the river Welland, on the ſouthern ſide of the county, to the river Witham, near Lincoln. Its channel, for nearly the whole of this courſe, an extent of upwards of forty miles, is ſixty feet in width, and has a broad flat bank on each ſide. This great canal receives from the hills all the draining and flowing waters, which take an eaſterly courſe, and which, but for this Catchwater drain, as it is now appropriately called, would ſerve to inundate the Fens. Several Roman coins have been found on the banks of this dyke. The whole of the preſent county is ſuppoſed to have been named by the Romans Lindum, and the principal ſtation or town Lindum colonia.

During the Anglo-Saxon dominion in England, Lincolnſhire was incorporated within the kingdom of Mercia, which, according to an old chronicle quoted by Leland, was then divided into two provinces, north and ſouth; and as the Trent was the line of ſeparation, the county of Lincoln conſtituted a conſiderable part of South Mercia. Crida was the firſt Mercian ſovereign, and began his reign in 586. At this time Mr. Turner, (Hiſtory of the Anglo-Saxons,) ſuppoſed that the whole iſland was governed by eight Anglo-Saxon monarchs; whence it ſhould rather be denominated an octarchy then an heptarchy. During the eſtabliſhment of theſe petty kingdoms, the Saxons were in conſtant warfare with the Romanized Britons; and after theſe were ſubdued, the former were repeatedly embroiled in conflicts with each other. In the midſt of theſe civil commotions Chriſtianity was introduced, and gradually made its progreſs through the iſland; giving a new turn to human purſuits, and diverting and engroſſing the attention of the barbarous heathens. Peada, the ſon of Penda, was the reigning monarch here, when this religion was accepted by the South Mercians: he founded a monaſtery at Meden-hamſted, now Peterborough. He was ſoon afterwards murdered, as ſuppoſed, by his wife. Edwin the Great, the firſt Chriſtian king of Northumberland, conquered the counties of Durham, Cheſter, Lancaſter, the Iſle of Man, and Angleſea, carried his arms ſouthward over the Trent, and obtained all the province of Lindſey. Paulinus, who converted him to Chriſtianity, preached the goſpel wherever that king's power extended. He built the cathedral of Southwell, a little weſt of Newark, baptized many thouſands in the river Trent, near to Tiovulfingaceſter, and converted Blecca, the governor of Lincoln. This was about the year 630. The learned and pious Alkfrid kept his court at Stamford in 658. After the death of Oſwy, king of Northumberland, Egfrid, his ſon, invaded Wulfere, and wreſted from him the whole province of Lindſey in Lincolnſhire. In 677 he erected the epiſcopal ſee of Sidnaceſter, in favour of Eadhed, who had been chaplain to his brother Alkfrid, king of Deira. In 683, Eadhed removed to Ripon, where he remained till his death. The ſouth Mercian kingdom and biſhop's ſee being thus eſtabliſhed, but few public events are recorded, till the incurſion of the Danes, who, in the year 870, laid waſte great part of Lincolnſhire, and burned the monaſteries of Bardney, Croyland, and Medenhamſted, putting all the monks to the ſword. After the defeat of the Danes by Alfred, the ſovereignty of Mercia fell into his power. He did not, however, avowedly incorporate it with Weſſex, but diſcontinued its regal honours; and during the reign of Edward the Elder, it was found neceſſary to conſtruct and fortify ſeveral places on the borders of Mercia joining Northumbria, particularly on the banks of the Humber. Mercia was ſoon afterwards annexed to Weſſex, but ſome places were ſtill held by the Danes; among theſe were the towns of Stamford and Lincoln, even ſo late as 941, when Edmund the Elder expelled them hence.

The maritime counties of England being more directly expoſed to attack from invading armies and piratical plunderers; and in the early part of our civil eſtabliſhments, being more populous than the midland country, were therefore frequently expoſed to the conflicts of warfare; and hence it is found that theſe diſtricts abounded with military works and caſtles or caſtellated manſions. Beſides the permanent ſtations of the Romans in Lincolnſhire, they threw up caſtrametations in different places; to guard the vallies, protect the great roads, and defend the mouths of the rivers. In the continued wars between the Anglo-Saxon kingdoms, theſe were again occupied by the contending parties; and after the Norman conqueſt, ſome of the moſt commanding were adopted by the conqueror's captains and barons, and then became heads of extenſive lordſhips. To deſcribe or diſcriminate them, is, and ever will be, impoſſible; for documents are wanting, and the innovations of the latter occupiers generally obſcured or annihilated all traces of their predeceſſors. Excluſive of the Roman ſtations, there are notices or remains of the following fortifications in this county. Encampments at or near Brockleſby, Hibberſton, Broughton, Roxby, Winterton cliffs, Aulkborough, Yarborough, South Ormſby, Burwell, Stamford, Caſtle-hill near Gainſborough, Winterington, Humington, Ingoldſby, Caſtle Carleton, Burgh, Brough, north of Caſton, Barrow. Caſtles, or remains at Horncaſtle, Tatterſhall, a noble remain, Bourne, only earth-works remaining, Caſtor, Somerton, Moor Tower, Stamford, Scrivelſby, Torkſey, a fine remain, Sleaford, only earth-works, Bollingbrook, Lincoln, with walls and gates, Folkingham, with large foſſæ, Kyme tower, and Huſſey tower, near Boſton, Pinchbeck, a moated manſion, Bitham.

According to the beſt authorities, the epiſcopal ſee was eſtabliſhed at Lincoln towards the cloſe of the eleventh century, previous to which era, the dioceſe had conſiſted of the two Anglo-Saxon ſees of Dorcheſter, now a village in Oxfordſhire, and Sidnaceſter a place bordering on the river Trent. The dioceſe of Lincoln is the largeſt in the whole kingdom, notwithſtanding thoſe of Oxford, Peterborough, and Ely, have been taken from it. It comprehends the counties of Lincoln, Leiceſter, Huntingdon, Bedford, and Buckingham, excepting the pariſhes of Monks, Riſborough, and Halton, which are peculiars of Canterbury; and Abbot's, Aſton, and Winſlow, (which, with fifteen other pariſhes that are in Hertfordſhire, and were taken hence, being made of exempt juriſdiction, and appropriated to the abbey of St. Albans, became, on the diſſolution of that monaſtery in 1541, part of the dioceſe of London.) The ſee alſo retains the greater part of Hertfordſhire, and ſeveral pariſhes in the counties of Oxford, Rutland, and Northampton. The whole dioceſe is divided into ſix archdeaconries; theſe are ſubdivided into fifty-two deaneries; the number of pariſhes is ſtated by Browne Willis to be, including donatives and chapels, 1517, of which 577 are impropriated; and the clergy's yearly tenths in this very extenſive juriſdiction 1751*l.* 14*s.* 6*d.* Camden ſays there are 630 pariſhes in this county. The monaſteries, hoſpitals, &c. connected with the cathedral and its eccleſiaſtical eſtabliſhment, were very numerous, and ſome of very extenſive influence.

The eccleſiaſtical architecture of Lincolnſhire has long been juſtly celebrated for its magnificence; and its numerous churches have been the ſubjects of admiration. It is remarkable that the moſt ſplendid edifices which adorn this diſtrict, were erected chiefly in its loweſt and moſt fenny ſituations, where all communication muſt formerly have been, and even to this day is extremely difficult. The eccleſiaſtical edifices in the diviſion of Lindſey, excepting the cathedral of Lincoln, are in general inferior to thoſe in Keſteven and Holland; but in the north-eaſtern part of this diviſion, which is bounded by the German ocean to the eaſt, and the highlands, called the Wolds, to the weſt, there are ſeveral churches, diſplaying much elegance in their architecture, and built of excellent materials. The diviſion of Keſteven abounds with churches ſplendid both in their plans and decorations. In the central part, the greater proportion of them is adorned with lofty ſpires; while many of thoſe in the northern and ſouthern extremities preſent handſome towers, frequently divided into three or four diſtinct ſtories, and formed of excellent materials and maſonry. The date of the churches in this diviſion, with the exception of thoſe of Sempringham and St. Leonard Stamford, is, in few inſtances, earlier than the thirteenth century. It is principally in the diviſion of Holland that Lincolnſhire boaſts of ſuperior excellence in eccleſiaſtical architecture; and it is really ſurpriſing that ſo many fine monaſtic buildings, and ſacred edifices, ſhould have been erected in a county ſo inconvenient for travelling, ſo unpleaſant to the eye, and ſo uncongenial with the common comforts of life; yet in this fenny and ſwampy diſtrict, are the churches of Boſton, Goſberton, Pinchbeck, Spalding, Holbeach, Gedney, Long-Sutton, Croyland, and many others, which have a juſt claim to univerſal admiration. The character and plan of the churches in this diviſion vary in different parts. Some are cruciform; many have ſpires in common with thoſe of Keſteven; while embattled towers at the weſt end form the principal feature of the remainder. Of the ſplendid church at Croyland, only a ſmall portion of the original ſtructure now remains; but ſufficient to ſhew that in its entire ſtate, it was not inferior to any of our cathedrals, either in ſize or architectural ornament. The ſtone employed in the erection of the edifices of this diſtrict is univerſally found to be of an excellent and durable ſpecies, ſtill retaining at the diſtance, in many inſtances, of ſix or ſeven centuries, its original face and firmneſs.

This county is more noted for its religious than for its civil architecture. Though of great extent, it contains but few manſions of conſequence, grandeur, or elegance, and thoſe are chiefly of modern erection. The following are the principal; Grimſthorpe caſtle; the ſeat of the duke of Ancaſter-Nocton; earl of Buckinghamſhire—Glentworth; earl of Scarborough—Brokleſby; lord Yarborough—Belton; lord Brownlow—Redbourn; lord William Beauclerk—Burton; lord Monſon—Doddington; lord Delaval—Bloxholm; Hon. colonel Manners—Manby; Hon. Charles Anderſon Pelham—Reveſby abbey; ſir Joſeph Banks, bart.

Lincolnſhire, and the counties of Eſſex, Cambridge, and Norfolk, have been generally deſcribed as particularly unfavourable to health; and from their contiguity to the ſea, with the numerous fens, meres, brooks, &c. with which they abound, are commonly ſtigmatized as producing peſtilential climates, only calculated to excite agues, cramps, and rheumatiſms. Theſe general maxims, though frequently originating in facts, are too often perverted, or extended beyond due bounds. Lincolnſhire may be ſaid to be in this predicament; for its name is commonly aſſociated with fens, flatneſs and bogs. Thoſe who reſide in, or have travelled over it, are enabled to appreciate and define its character. Arthur Young has pointed out and deſcribed many features and places in this county, that may be referred to as partaking of the beautiful and pictureſque:—"About Belton," he ſays, "are fine views from the tower on Belmont; Lynn and the Norfolk cliffs are viſible, Nottingham caſtle alſo, the vale of Belvoir, &c. And in going by the Cliff towns to Lincoln, there are many fine views. From Fullbeck to Leadenham, eſpecially at the latter place, there is a moſt rich proſpect over the vale of the Trent to the diſtant lands that bound it. Theſe views, over an extenſive vale, are ſtriking, and of the ſame features as thoſe from the cliff-road to the north of Lincoln, to Kirton, where is a great view both eaſt and weſt to the Wolds, and alſo to Nottinghamſhire. Near Gainſborough there are very agreeable ſcenes; from the plantation of H. Dalton, of Knaith, and from the chateau battery of Mr. Hutton, of Burton, the view of the windings of the Trent, and the rich level plain of meadow, all alive with great herds of cattle, bounded by diſtant hills of cultivation, are features of an agreeable county. But ſtill more beautiful is that about Trentfall; from ſir John Sheffield's hanging wood, and the Rev. Mr. Sheffield's ornamented walk, following the cliff to Alkborough, where Mr. Goulton's beautiful grounds command a great view of the three rivers; as the ſoil is dry, the woods lofty, and the county various, this muſt be eſteemed a noble ſcenery, and a perfect contraſt to what Lincolnſhire is often repreſented by thoſe who have only ſeen the parts of it that are very different. The whole line of the Humber hence to Grimſby, when viewed from the higher wolds, preſents an object that muſt be intereſting to all. This, with the very great plantation of lord Yarborough, are ſeen to much advantage, from that moſt beautiful building, the mauſoleum at Brocklesby." Many other parts of the county might be pointed out as preſenting in themſelves, or commanding, intereſting ſcenery. The country around Grantham, alſo in the vicinity of Louth, and that more particularly between Bourn and the former place, including the noble and ſpacious woods of Grimſthorpe, abound with that inequality of ſurface, that diverſified interchange of hill and dale, wood and lawn, which conſtitute the pictureſque and beautiful in natural ſcenery.

Lincolnſhire may be ſaid to preſent three great natural features, each of which has a ſpecific and nearly uniform character. Theſe are the wolds, heaths, and fens. The latter occupy the ſouth-eaſtern ſide of the county, and though formerly a mere waſte and perfectly ſterile, have been, by means of drainage, &c. rendered ſubſervient to agriculture; many parts indeed may be pronounced uncommonly fertile. On the ſea coaſt, towards the north part of the county, this tract is narrow; near the Humber it contracts to a mere ſtrip of land. The heaths, north and ſouth of Lincoln, and the wolds, are calcareous hills, which, from their brows, command many fine views over the lower regions. The reſt of the county is not equally diſcriminated, either by fertility or elevation. "The heath, now nearly incloſed," ſays Arthur Young, "is a tract of high country, a ſort of back bone to the whole, in which the ſoil is a good ſandy loam, but with clay enough in it to be ſlippery with wet, and tenacious under bad management; but excellent turnip and barley land, on a bed of lime-ſtones, at various depths, from ſix inches to ſeveral feet, commonly nine inches to eighteen. This hill ſlopes ſharply to the weſt; the declivity of the ſame nature, but generally good; and this extends ſome diſtance in the flat vale, for the firſt line of villages, (built alſo as the ſoil lies in a longitudinal direction north and ſouth.) The ſoil is rich loam, containing much paſturage." Between Gainſborough and Newark, for twenty-five miles, is a large tract of flat ſandy ſoil, the greater part of which has been incloſed, and partly drained. The ſoil of the iſle of Acholme may be ſaid to be among the fineſt in England. It conſiſts of black ſandy loams, warp land, brown ſand, and rich loams of a ſoapy and tenacious quality. The under ſtratum at Stacey, Belton, &c. is, in many places, an imperfect plaſter ſtone. Reſpecting the general products of the county, the higher grounds are now moſtly incloſed, and appropriated to tillage, and produce all ſorts of grain. Some of the wolds, however, are not yet divided, but are devoted to ſheep and rabbits. The lower lands that have been drained and incloſed, produce abundant crops of oats, hemp, flax, &c.

Lincolnſhire has long been famous for a breed of fine horſes; but the adjoining county of York has now the credit for rearing many that are actually bred in this county. In ſome diſtricts great numbers of mares are kept for the ſole purpoſe of breeding. In Holland Diviſion almoſt every farmer keeps ſome; and the number of colts reared is very great. The neat cattle of this county are deſcribed by Mr. Stone as being, for the greateſt part, of a large ſort, having great heads and ſhort horns; ſtout in the bone, and deep in the belly; with ſhort necks and fleſhy quarters, narrow hips and chines, high in their rumps, and bare on the ſhoulders. The cows, he remarks, when fat, weigh from eight to nine hundred, and the oxen from ten to twelve hundred. The moſt profitable ſtock of the county appears to be ſheep. Numbers are bred and fattened in this part of the kingdom. Large quantities of wool are thence obtained, to ſupply the demands of the neighbouring diſtricts. It is a curious fact, that while ſo much has been ſaid in commendation of the Leiceſterſhire breed, the Lincolnſhire, which is the ſame, ſhould have been paſſed over in ſilence. Mr. Stone ſays, theſe ſheep are not even varieties. The Lincolnſhire, a large horned animal, adapted for the rich grazing and marſh land of the county; generally weighs well when fat, and bears a heavy fleece of coarſe but long ſtapled wool; the weight, per fleece, is eight pounds and upwards. Mr. Young mentions a ſheep ſold at Smithfield, which clipped, the firſt year, 23lb. of wool, and in the ſecond year, 22½lb. Few manufactures are eſtabliſhed in this county; but here are two objects of conſiderable merchandize, rabbits' fur, and gooſe feathers. Theſe were formerly of great conſequence, and furniſhed articles of extenſive trade. From the ſyſtem of incloſing, now ſo extenſively adopted, both rabbits and geeſe are much diminiſhed.

The rabbit warrens of this county were formerly much more extenſive than at preſent. and were preſerved on a principle of improvement; ſome being broken up for tillage, and others, which had been under tilth, being again laid down for this purpoſe. The ſoil of old warrens, by the rabbits continually ſtirring and ventilating the earth in burrowing, has been found incomparably better than lands of a like nature left in their original ſtate. The fecundity of rabbits was a circumſtance of no ſmall conſequence, when the ſkins of large well-choſen rabbits would produce *2s. 6d.* or *3s.* each: at that time they were uſed in making muffs, tippets, lining robes, &c.: the down was alſo employed in hats. As the ſkins conſtitute the principal profit of the proprietor, it becomes a primary object with him to attend to the breeding, killing, &c.: ſkins that are free from black ſpots on the inſide are ſaid to be in ſeaſon. The trade is now on the decline, not only from the diminution in the value of the ſkins, but alſo from the means of conducting it becoming daily more circumſcribed, it being now thought good huſbandry to deſtroy the warrens, and apply the land to other uſes. The number of warrens in this county has been greatly reduced, yet many thouſand acres are ſtill devoted to this kind of ſtock.

Many of what are called the fens, are in a ſtate of waſte, and ſerve for little other purpoſe than breeding and rearing geeſe, which are conſidered the fenman's treaſure. They are a highly valuable ſtock, aud live where, in the preſent ſtate of thoſe lands, nothing elſe will: they are very prolific, and the young quickly become ſaleable, or ſpeedily contribute to increaſe the ſtock. The feathers are very valuable; and however trifling it may appear, the ſale of quills alone amount, on a large flock, to a conſiderable ſum. "During the breeding ſeaſon," Mr. Gough ſays, "theſe birds are lodged in the ſame houſes with the inhabitants, and even their very bed-chambers; in every apartment are three rows of coarſe wicker pens, placed one above another; each bird has its ſeparate lodge, divided from the other, which it keeps poſſeſſion of during the time of ſitting. A gozzard, or gooſeherd, attends the flock, and twice a day drives the whole to water, then brings them back to their habitation, helping thoſe that live in the upper ſtories to their neſts, without ever miſplacing a ſingle bird." The geeſe are uſually plucked five times in the year: at Lady-day for quills and feathers, and again at Midſummer, Lammas, Michaelmas, and Martinmas. Goſlings are not ſpared, as early plucking tends to increaſe the ſucceeding feathers. Mr. Young ſtates, that "the feathers of a dead gooſe are worth ſixpence, three giving a pound; but plucking alive does not yield more than three-pence a head *per annum*. Some wing them only once every quarter, taking ten feathers from each gooſe, which ſell at five ſhillings a thouſand. Plucked geeſe pay, in feathers, one ſhilling a head in Wildmore Fen." The common mode of plucking live geeſe is conſidered a barbarous cuſtom; but it has, perhaps, prevailed ever ſince feather beds came into general uſe. The mere plucking is ſaid to hurt the bird but little, as the owners are careful not to pull before the feathers are ripe, that is, juſt ready to fall: if forced from the ſkin ſooner they are of inferior value.

The general improvements that have been effected in this county within the laſt twenty years, and that are now gradually making, have co-operated to alter the general appearance, the agriculture, climate, &c. ſo materially, that the ſurface has aſſumed a new aſpect, the value of land is greatly increaſed, the means of ſocial and commercial communication have been facilitated, and the comforts of domeſtic life greatly promoted. Yet there is ſtill ſcope for material improvements: for the roads, in many parts of the county, are in a very bad ſtate; and the traveller has not advantages adequate to the tolls levied on him. In the vicinity of Boſton, Spalding, and Louth, the commiſſioners have commenced a plan for forming firm and ſubſtantial roads. This is moſtly done by laying ſhingles, brought from the Norfolk coaſt, in the centre of the road, and mixing them with the ſilt of the place.

The wolds extend from Spilſby, in a north-weſterly direction, for about 40 miles to Barton, near the Humber. They are, on an average, nearly eight miles in breadth, of ſand and ſandy loam, upon flinty loam, with a ſubſtratum of chalk. Beneath this line lies an extenſive tract of land at the foot of the wolds, called the marſh, which is ſecured from the encroachments of the ſea by embankments, and is agriculturally divided into north and ſouth marſhes by a difference in the ſoil.

The fens of this county form one of its moſt prominent features. They conſiſt of lands which, at ſome diſtant period, have been inundated by the ſea, and by human art have been recovered from it. In the ſummer they exhibit immenſe tracts, chiefly of grazing land, interſected by deep ditches, called droves, which ſerve both for fences and drains. Theſe are accompanied generally by parallel banks, upon which the roads paſs, and are intended to keep the waters, in flood time, from overflowing the adjacent lands. They not only communicate with each other, but alſo with larger canals, called dykes and drains, which, in ſome inſtances, are navigable for boats and barges. At the lower end of theſe are ſluices, guarded by gates, termed gowts. During the ſummer, numerous flocks and herds are ſeen grazing over this monotonous ſcene, and many of the paſtures afford a luxuriant herbage: but in the winter, or in the autumn, if it ſhould prove wet, the aſpect is changed; the cattle quickly diſappear, and the eye muſt paſs over thouſands of acres of water or ice, before it can find an object on which to reſt. Several cauſes combine to produce this drowning of the lands. Many of the fens lie below the level of the ſea; ſome are lower than the beds of the rivers; and all are beneath the high-water mark of their reſpective drains. The ſubſtratum of the fens is ſilt, or ſea-ſand, which is a well-known conductor of water. Through this, when the drains are full, the ſea-water filters; and, unable to paſs by the drains, riſes on the ſurface, and is known by the name of ſoak. Dugdale was of opinion, that there was a time when theſe parts were not inundated. In his hiſtory of embanking, he obſerves, that the iſle of Axholme, though for many ages it hath been a fenny tract, was not anciently ſo, but was originally a *woody* country, not annoyed with theſe inundations, as is evident from the great numbers of trees which had been found in the moor. The ſame author, ſpeaking of the great level, gives his opinion that it was formerly firm and dry land, neither annoyed with ſtagnation of freſh waters, nor inundations from the ſea; and this he ſuppoſes was the caſe of the fens in Lincolnſhire, and the adjoining counties: for it is an eſtabliſhed fact, that large timber trees will not thrive in watery lands, and ſuch have been found lying in the earth abundantly in this country.

The principal rivers which either riſe in the county, paſs through it, or are connected with it, are the Trent, the Ancholme, the Witham, the Welland, and the Glen. The Trent, though not properly a river of this county, forms the boundary of it on the north-weſtern ſide, from the village of North Clifford to that of Stockworth; whence it conſtitutes the eaſtern boundary of the iſle of Axholme: it thence flows to Aldborough, and having received the Dun and the Ouſe, mingles its waters with the Humber. From Gainſborough, where it is croſſed by a handſome bridge, it is navigable for coals, corn, and various articles of commerce. The Ancholme is a ſmall river, riſing in the wolds, near Market-Raiſin, whence it is navigable to the Humber, into which it falls ſome miles below the junction of the Trent. The Welland has its ſource near Sibertoff, in Northamptonſhire; and being increaſed by numerous ſtreams, paſſes Market-Deeping; where, entering the fens, it leaves a portion of its waters and ſludge, which it had accumulated in its previous paſſage through the rich lands of Northamptonſhire, Leiceſterſhire, and Rutlandſhire. It afterwards meets the contributory Glen, and empties itſelf into Foſsdyke-Waſh, eaſt of Boſton. The Witham, which is completely a river of this county, derives its origin near South-Witham; and thence flows almoſt due north, through the park of Eaſton, and to Great Ponton. It proceeds through a wide valley to Lincoln: continuing its courſe to Boſton, it unites its waters with the ſea at a place called Boſton-Deeps. Much of the preſent bed of the river, from Boſton upwards, is a new cut, made for the purpoſe of widening the channel, rendering it more commodious for navigation, and better adapted to receive and carry off the water of the contiguous fens. Theſe rivers, with thoſe of the Grant, Ouſe, and Nene, in the adjacent counties, from the obſtructions they meet in delivering their waters to the ocean, form one great cauſe of inundating ſo large a portion of valuable land. In viewing the various inlets of the ſea, it is ſurpriſing to obſerve the immenſe quantity of ſand and ſludge which is continually depoſiting on the ſhore. This is owing to the nature of the tides, which, from the form of the channel, flow with more violence than they ebb. Hence the mouths of the rivers are choaked up, and the deſcending waters are thrown back on the low-lands. The great bay, or eſtuary, into which the different rivers, paſſing through the fens, are emptied, is very ſhallow, and full of ſhifting ſands and ſilt.

That this diſtrict was thus flooded at a very remote period, is evident from the plans of embanking and draining which the Romans adopted, in order to counteract the miſchievous effects of ſuch inundations. Since their departure, much has been done at various times for the improvement of the fen country; and an immenſe expence has been occaſionally, and is ſtill annually, incurred, to prevent the encroachment of the water, and to ameliorate the ſoil. A very brief notice of theſe endeavours will tend to give ſome idea of the country, and to illuſtrate thoſe periods of hiſtory. Deeping-Fen, on the banks of the Welland, appears to have received the earlieſt attention: for, at the beginning of Edward the Confeſſor's reign, (as Ingulphus relates,) a road was made acroſs it by Egelric, formerly a monk of Peterborough, but at that time biſhop of Durham. In the time of the Conqueror, Richard de Rulos, the king's chamberlain, incloſed this part of the fen-country from the chapel of St. Guthlake to Cardyke, and to Clevelake near Cranmore; excluding the river Welland by a large and extenſive bank of earth. The Foſs-Dyke is an artificial trench, extending about ſeven miles in length, from the great marſh near the city of Lincoln to the river Trent in the vicinity of Torkſey. This was made or materially altered by king Henry I. in the year 1121, for the purpoſe of navigation, and for making a general drain for the adjacent level. From its paſſing through ſuch a flat country, the water could have but a ſlow current, whereby it became unnavigable from the accumulation of mud, ſo that it was ſoon found neceſſary to cleanſe it. Of the marſhes on the river Ancholme, the firſt account on record is the 16th of Edward I. In ſucceeding reigns, various ſtatutes were enacted for rendering effectual the drainage of this part of the country. The iſland of Axholme, though now containing ſome of the richeſt land in the kingdom, was formerly one continued fen, occaſioned by the ſilt thrown up the Trent with the tides of the Humber. This obſtructing the free paſſage of the Dun and the Idle, forced back their waters over the circumjacent lands, ſo that the higher central parts formed an iſland, which appellation they ſtill retain. In the firſt of Edward III., and in ſeveral ſucceeding reigns, commiſſions were granted for repairing the banks and ditches, as they fell to decay. Early in Charles I.'s reign, that great work was commenced, which embraced not only the marſhes of Axholme, but of all the adjacent fens, called Dikeſmarſh and Hatfield chaſe, in the county of York. Theſe comprehended an extent of lands which were not only drowned in winter, but even in ſummer were ſo deeply covered with water, that boats could navigate over 60,000 acres. It is traditionally affirmed that large veſſels could ſail up the river Witham from Boſton to Lincoln; and from the ribs, timbers, &c. of ſhips, that have been frequently found near it, the tradition ſeems to be juſtified. At preſent, it is only adapted for barges, and the flow of the current is ſo ſmall, that it does not cleanſe the bed of the river. The firſt notice of the inconveniences ariſing from the obſtruction of its waters, appears in the ſixth year of Edward III., when commiſſioners were appointed for ſurveying the ſame. In conſequence of their report, and of various ſurveys and preſentments in different reigns, ſucceſſive regulations were made for reſtraining the waters within due bounds, and delivering the land-floods ſpeedily to the ſea. But in the fifteenth of Henry VII., more effectual meaſures were thought neceſſary to be adopted for furthering the deſign; and an able engineer, Mayhave Hake, of Graveling in Flanders, was invited over to put it into execution. It was accordingly covenanted between him and the king's commiſſioners, "that the ſaid Mayhave Hake ſhould bring with him from Flanders fourteen maſons, and four labourers, to make him a proper ſluice and dam near the town of Boſton, ſufficient for its future ſafeguard. For which they were to be remunerated as follows: Mayhave Hake, for himſelf and man, per diem 4*s.*; maſons and ſtone-hewers, per week, 5*s.*; labourers, per week, 4*s.* The ſaid Mayhave Hake to receive 50*l.* more on the completion of the work.—Should any more workmen be neceſſary they ſhould be provided at the expence of the inhabitants of Boſton, and the level of Holland and Keſteven." To the north and north-eaſt of the Witham, are the large fenny tracts called Wildmore Fen, Weſt Fen, and Eaſt Fen, in the latter of which, it appears by a writ, 41 Elizabeth, 5000 acres were drowned. A plan is now executing under the direction of that very ſcientific and able engineer Mr. John Rennie, by which theſe three fens will be effectually drained, and the lowlands of this part of the county be rendered productive and profitable.

Lincolnſhire conſiſts of three great diviſions; Holland, Keſteven, and Lindſey; which are ſubdivided into 32 hundreds, wapentakes, and ſokes; containing in the whole one city, 31 market-towns, 657 villages. Twelve members are returned to parliament; two for the ſhire, two for the city, and two from each of the boroughs of Boſton, Grantham, Great Grimſby, and Stamford. Spalding and Waynfleet were repreſented in the eleventh year of Edward III. This county, from its extent and opulence, is not under the influence of any individual; and in conteſted elections the freedom of the people is not ſo liable to corruption as in ſmaller counties and property boroughs. Beauties of England and Wales, vol. ix. Stone's Agricultural Survey of Lincolnſhire. Young's Ditto.

LINCOLNTOWN, a poſt-town of America, in North Carolina, and capital of Lincoln county, containing about 35 or 40 houſes, a court-houſe, gaol, and church; 46 miles from Morgantown.

LINCOLNVILLE, a town of Hancock county, in the ſtate of Maine, on the W. ſide of Penobſcot bay; 12 miles from Belfaſt.

LINCONIA, in *Botany*, a name given by Linnæus, but of whoſe origin or derivation we are unable to trace any thing.—Linn. Mant. 147. Schreb. 170. Willd. Sp. Pl. v. 1. 1296. Juſſ. 442.—Claſs and order, *Pentandria Digynia.* Nat. Ord. *Incertæ ſedis*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of four ovate, permanent leaves, the inferior oppoſite pair ſhorter. *Cor.* Petals five, lanceolate, ſeſſile, erect. Nectary a cavity impreſſed at the baſe of the petals, ſurrounded below by a margin. *Stam.* Filaments five, awl-ſhaped, bordered, erect, of middling length; anthers obtuſe, arrow-ſhaped, burſting towards the baſe of each lobe. *Piſt.* Germen half inferior with reſpect to the corolla, but ſuperior with reſpect to the calyx; ſtyles two, thread-ſhaped, ſtriated; ſtigmas ſimple. *Peric.* Capſule of two cells. *Seeds* two?

Linnæus obſerves that if the perianth may be taken for bracteas, the flower is altogether ſuperior, but this does not ſeem correct.

Eſſ. Ch. Petals five, having each a honey-bearing cavity at their baſe. Capſule of two cells, half inferior.

1. L. *alopecuroidea.* Linn. Mant. 216. Syſt. Veg. ed. 14. 261.—A native of mountainous watery places at the Cape of Good Hope. This is a *ſhrub* furniſhed with wand-like determinate *branches*, ſcarred with the baſes of the fallen leaves, as in the fir tribe. *Leaves* ſcattered, or ſomewhat whorled, about five or ſix in a whorl, almoſt ſeſſile, linear, triangular, channelled, rigid, ſhining, appearing curiouſly granulated under a microſcope, an inch long, rough at the angles, the upper ones fringed. *Flowers* about the tops of the branches, lateral, ſeſſile, the length of the leaves, permanent, fleſh-coloured, or white.

LINCTUS, a form of medicine, the ſame as *lambative*, *lohoch*, and *eclegma*.

LINDA, in *Geography*, a ſmall iſland in the Indian ſea, near the coaſt of Africa, at the mouth of the Zambeſe.

LINDAHL, a town of Norway; 140 miles N. of Chriſtiania.

LINDANUS, William, in *Biography*, a celebrated Dutch divine, was born at Dort, in Holland, in the year 1525. He purſued his academical ſtudies at Louvain, and afterwards went to France to perfect himſelf in the Greek and Hebrew languages. Having returned to Louvain, he was ordained a prieſt, and admitted a licentiate in divinity. This was in the year 1552, and in the following year he undertook the office of lecturer on the ſacred ſcriptures at Dillingen, which poſt he filled for three years with high reputation. He took his degree of D.D. in 1556, after which he was appointed dean of the Hague; counſellor to the king; vicar to the biſhop of Utrecht, and inquiſitor of the faith within the ſame eccleſiaſtical juriſdiction. On account of his great zeal in the latter office, the duties of which he performed with much ſeverity, he was nominated, by the bigotted Philip II. of Spain, to the biſhopric of Ruremond. In 1568 he went to Rome, and was received by pope Gregory XIII. and the cardinals with ſingular marks of reſpect and eſteem. On his return he exerciſed the functions of a Chriſtian biſhop in a very honourable manner, applying the revenues of his ſee to the relief of the indigent, and viſiting every part of his dioceſe for the purpoſe of perſonally comforting, inſtructing, and aſſiſting thoſe who ſtood in need of temporal or ſpiritual aid. After a ſecond journey to Rome, he was appointed, in 1588, to the biſhopric of Ghent, an office which he held but three months, when he died in the ſixty-third year of his age. He was reckoned a very learned man and an able divine. His writings are numerous, conſiſting of Polemical treatiſes; Paraphraſes on many of the Pſalms, and the Pſalter, illuſtrated with Greek and Hebrew texts: but his moſt valued publication is entitled "Panoplia Evangelica." Moreri.

LINDAR, in *Geography*, a town of Iſtria; 5 miles N.E. of Mittenburg.

LINDAU, an imperial city of Germany, ſeated on an iſland in the lake of Conſtance, and communicating with the continent by means of a bridge. The iſland is ſo divided by an arm of the lake, as to form another ſmaller iſland, which is ſeparated from the city, and conſiſts of vineyards and garden encloſed within a wall. Lindau, from its peculiar ſituation, has been called the Venice of Swabia. Moſt of the burghers are Lutherans. This city contains, beſides a pariſh church dedicated to St. Stephen, a well-endowed hoſpital, and a grammar-ſchool. The caſtle, and Heyden Maur, or Heathen wall, as it is called, are reckoned Roman works; the latter being aſcribed to Tiberius Nero, and the former to Conſtantinus Chlorus, during their encampments here, in their expeditions againſt the Vindelici and Alemanni. It is ſuppoſed that near this caſtle formerly ſtood a church, and that the little church of St. Peter here was built on the firſt introduction of Chriſtianity into this country. The territory of Lindau comprehends 14 villages; 19 miles E. of Conſtance. N. lat. 47° 28′. E. long. 10° 35′.—Alſo, a town and caſtle of Hungary; 17 miles N.N.W. of Cſakathurn.—Alſo, a town of Weſtphalia, in the territory of Eichfeld, ſituated on the Rhine; 12 miles N.W. of Duderſtadt.—Alſo, a town of Germany, in the principality of Anhalt Zerbſt; 5 miles N. of Zerbſt.—Alſo, a town of Germany, in the principality of Bayreuth; 8 miles N.W. of Bayreuth.

LINDE, or Lindesberg, a town of Sweden, in Weſtmanland, ſituated between two lakes; built by queen Chriſtina in 1644; near it is a medicinal ſpring; 85 miles W.N.W. of Stockholm. N. lat. 59° 35′. E. long. 14° 56′.

LINDEAL, a town of Hindooſtan, in the circar of Cuddapa; 25 miles N. of Gandicotta.

LINDECK, a town of the duchy of Stiria; 8 miles N. of Cilley.

LINDEN, a town of Germany, in the principality of Culmbach; 6 miles N. of Neuſtadt.

LINDENAU, a town of Pruſſia, in the palatinate of Thorn; 20 miles N.E. of Culm.—Alſo, a town of Sileſia, in the principality of Neiſſe; 6 miles N.W. of Patſchkau.

LINDENBERG, a town of Germany, in the principality of Bayreuth; 9 miles E.S.E. of Bayreuth.

LINDENBRUCH, Frederic, in *Biography*, a learned philologiſt of the ſeventeenth century, was a native of Flanders, and died in 1638. He wrote notes on Terence, on the fragments of certain Latin poets, and on Ammianus Marcellinus. He alſo publiſhed "Codex Legum-Antiquarum, ſeu Leges Wiſigothorum, Burgundionum, Longobardorum, &c." which is eſteemed a very curious work. Moreri.

LINDENFELS, in *Geography*, a town of Germany, in the palatinate of the Rhine; 14 miles N.N.E. of Manheim.

LINDENHARDT, a town of Germany, in the principality of Bayreuth; 9 miles S. of Bayreuth.

LINDER, a town of Iſtria; 12 miles N.N.E. of Pedena.

LINDERA, in *Botany*, a name dedicated by Thunberg to the memory of John Linder, a phyſician at Stockholm, afterwards ennobled by the name of Lindeſtolpe, who was born in the year 1678, and died in 1724. He was a celebrated Swediſh botaniſt, and author of the *Flora Wikſbergenſis*, publiſhed at Stockholm in 1728. His inaugural theſis "*de Heſperidum pomis*" was publiſhed at Abo in 1702. About ſix years afterwards appeared his treatiſe "de Venenis" printed at Leyden; a poſthumous edition of which was publiſhed at Leipſic in 1739, under the direction of M. Stenzelius. This is ſaid to be a maſterly diſſertation on vegetable poiſons.—He was alſo the author of an eſſay upon the colouring properties of ſeveral Swediſh plants, particularly of ſome Lichens.—Thunb. Jap. 9. Nov. Gen. 64. Schreb. 232. Willd. Sp. Pl. v. 2. 230. Juſſ. 429. Lamarck Illuſtr. t. 263.—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Incertæ ſedis*, Juſſ.

Gen. Ch. *Cal.* Perianth none. *Cor.* Petals ſix, ovate, obtuſe. *Stam.* Filaments ſix, many times ſhorter than the corolla; anthers very ſmall. *Piſt.* Germen ſuperior, ovate, ſmooth; ſtyle erect, a little ſhorter than the corolla; ſtigmas two, reflexed. *Peric.* Capſule of two cells. *Seeds* . . . . .

Eſſ. Ch. Corolla of ſix petals. Capſule of two cells.

1. *L. umbellata.* Thunb. Japon. 145. t. 21. Linn. Syſt. Veg. ed. 14. 339. (Kuro Noſji; Kæmpf. Amœn. 908.) Found on the mountains of Japan, flowering in April and May.—*Stem* ſhrubby, branched, ſpreading and weak. *Branches* alternate, zigzag, ſmooth. *Leaves* cluſtered at the extremity of the branches, on footſtalks, oblong, acute, undivided, about an inch long; ſmooth and green above; hairy and paler beneath. *Flowers* terminal, in ſimple, many-flowered umbels.

Thunberg informs us that the Japoneſe make ſmall bruſhes of the wood of this plant for cleaning the teeth.

Lindera is alſo the name of a genus in Adanſon, Familles des Plantes, v. 2. 499, by which he ſeems to have intended to honour Dr. Lindern. (See Lindernia.) His plant appears to be a *Chærophyllum*.

LINDERKREUZ, in *Geography*, a town of Saxony, in the circle of Neuſtadt; 8 miles N.W. of Weyda.

LINDERNIA, in *Botany*, ſo called by Allioni, in honour of Francis Balthazar von Lindern, a phyſician at Straſburg, who lived in the early part of the laſt century, and appears to have graduated at Jena, where his inaugural diſſertation, "*de Vermibus*," was publiſhed in 1707.—As a botaniſt he is known from the following works, *Tournefortius Alſaticus*, publiſhed in 8vo. at Straſburg, in 1728,—and *Hortus Alſaticus*, in 1747. The latter contains an account of the plants growing in the province of Alſatia, and eſpecially about Straſburg. Both the works are accompanied by a few plates.—Allion. Ped. v. 1. 57. Linn. Mant. 154. Schreb. 416. Willd. Sp. Pl. v. 3. 325. Mart. Mill. Dict. v. 3. Juſſ. 122. Brown. Prodr. Nov. Holl. 440. Lamarck Illuſtr. t. 522.—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Scrophulariæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of five, deep linear, acute, equal, permanent diviſions. *Cor.* of one petal, gaping, two-lipped; upper lip very ſhort, concave, emarginate; lower erect, trifid, the middle ſegment rather larger. *Stam.* Filaments four, in pairs, the two upper ones ſimple, the two lower aſcending, with a terminal, ſtraight tooth; anthers twin, the lower ones as it were lateral. *Piſt.* Germen ſuperior, ovate; ſtyle thread-ſhaped; ſtigma emarginate. *Peric.* Capſule oval, of one cell and two valves. *Seeds* numerous. *Recept.* cylindrical.

Eſſ. Ch. Calyx deeply five-cleft. Corolla ringent, the upper lip very ſhort. The two inferior ſtamens having a terminating tooth and a ſublateral anther. Capſule of one cell.

1. L. *Pyxidaria.* Linn. Mant. 252. Allion. Miſc. Taur. v. 3. 178. t. 5. Icon. Taur. v. 16. t. 84. (Capraria gratioloides; Linn. Sp. Pl. 876. Pyxidaria repens annua; Lindern. Tournef. Alſat. 156. t. 5. Hort. Alſat. 269. Gratiola floribus pedunculatis; Gron. Virg. 3.)—Leaves oval, entire, ſeſſile. Peduncles ſolitary.—Originally a native of Virginia, in ſpongy, inundated marſhes, whence it was brought into Europe, and may at preſent be found in ſimilar ſituations, in Alſace and Piedmont, flowering in July and Auguſt.—*Root* annual. *Stem* ſmooth, ſquare, brittle, occaſionally branched and creeping. *Leaves* oppoſite, ſmall, ſlightly notched, like thoſe of Anagallis. *Flowers* axillary, ſolitary, of a pale blue colour.

2. L. *dianthera.* Swartz. Prod. 92. Ind. Occ. 1058. (Erinus procumbens; Mill. Dict. n. 6.)—Leaves on footſtalks, ovate or roundiſh, ſlightly ſerrated. Stem creeping. —A native of moiſt ſand or clay in Hiſpaniola.—*Root* thread-ſhaped, with ſhort fibres. *Stem* herbaceous, looſely ſpreading. *Branches* aſcending, ſquare, ſmooth. *Leaves* oppoſite, ribbed, ſcarcely veined. *Flowers* ſmall.

3. L. *japonica.* Linn. Syſt. Veg. ed. 14. 567. Thunb. Japon. 253.—Leaves obovate, toothed, the lower ones on footſtalks. A native of Japan, where it flowers through the ſpring. *Root* annual. *Stem* herbaceous, branched, weak. *Branches* alternate, from an inch to a ſpan in length. *Radical leaves* numerous; *ſtem-leaves* few, ſeſſile, all obovate, obtuſe, toothed, very ſlightly hairy. *Flowers* in cluſters at the extremities of the branches.

Theſe two ſpecies laſt deſcribed are ſaid by the ingenious Mr. Brown, in his Prodromus to the Flora of New Holland, to be certainly different in genus from *L. Pyxidaria.* The ſame author deſcribes the three following new ſpecies of *Lindernia*, all natives of the tropical part of New Holland, though he remarks that they do not altogether accord with the original character of this genus.

L. *alſinoides.* Leaves ovate, entire or ſlightly toothed: ſtem-leaves diſtant: floral-ones ſmall. Tube of the corolla a little longer than the calyx. Stem erect.

L. *ſcapigera.* Leaves broad-ovate, nearly entire: lower ones crowded together: thoſe of the ſtem few and ſmall: floral leaves minute. Tube of the corolla twice as long as the calyx.

L. *ſubulata.* Leaves linear-awl-ſhaped, entire. Found by the Rt. Hon. ſir Joſeph Banks only.

LINDERUPOE, in *Geography*, a ſmall iſland of Denmark, in the Little Belt, near the coaſt of Sleſwick; 8 miles W.S.W. of Aſſens in the iſland of Funen.

LINDESNESS, or *the Naze*, a cape on the S. coaſt of Norway, in the North ſea, connected with the land by a very narrow iſthmus. The cape projects into the ſea about a Norway mile towards the S.W., and is about half a mile broad. The promontory is high, rocky, and barren, and has upon it twelve houſes of peaſants. N. lat. 58° 1′. E. long. 7° 12′.

LINDEWEISE, a town of Sileſia, in the principality of Neiſſe; 11 miles S.E. of Neiſſe.

LINDISFARNE, or *Holy Iſland*, an iſland ſituated in the North ſea, oppoſite to the coaſt of that portion of Durham which lies between the river Tweed and the county of Northumberland, England. It was named by the Britons Inis-Mendicante. The appellation Holy Iſland was given to it by the Engliſh from being the reſidence of ſeveral of the primitive fathers of the Saxon church. The diſtance of this iſland from the Mainland is about two miles. It is eaſily acceſſible at low water to all kinds of conveyance, but the ſands are dangerous to ſuch perſons as are unacquainted with them. The circumference of this iſland is about nine miles, and the number of acres contained in it 1020, nearly one-half of which are mere ſand-banks. The other grounds are rather of a rich ſoil; but previous to the year 1792, when the common was incloſed, only 40 acres were in tillage. The rental increaſed between the years 1790 and 1797, from 320*l.* to 396*l.* The town is ſituated on the weſt corner, and in 1798 was inhabited by 379 perſons, who were chiefly employed in fiſhing. From the names and ruins of ſeveral ſtreets it is conjectured to have been at one period much more conſiderable than it now is. In the year 635 this place was made a biſhop's ſee by king Oſwald. Its firſt prelate was a Scotchman of the name of Aiden. The church, or monaſtery, originally conſiſted of timber and thatch. St. Cuthbert, the ſaint to whom it was dedicated, was buried here; but after the Danes began their depredations, the monks removed to Cheſter-le-ſtreet, and carried the ſaint's body along with them. After their flight the invaders deſtroyed the building, which however ſeems to have been ſubſequently rebuilt, at leaſt in part. Various detached portions of this edifice are ſtill ſtanding. Portions of the church conſtitute the principal ruins. The north and ſouth walls of it are ſtill almoſt entire, though much out of the perpendicular. So likewiſe is a part of the weſt wall, but that on the eaſt is nearly level with the ground. All the arches of this church are circular, except two in the chancel and one in the north aiſle, but theſe, as well as a pointed arch over the north aiſle, ſeem to be of later date than the reſt of the building. The columns of the nave are of four kinds, very maſſy, and variouſly ornamented. The baſes and capitals are plain. Over each arch are large windows in pairs, and over them again are ſmaller arches. One of the ribs of the arch, which ſupported the tower, is ſtill ſtanding. It is richly ornamented with Saxon zigzag, as is alſo the weſtern door and ſome other arches. The ſtones of which this church is conſtructed are of a deep red colour. On the ſides moſt expoſed to the weather they are eaten into the ſemblance of honeycomb. The remains of the priory and offices lie on the ſouth ſide. The inſide of their walls is built of whin-ſtone, obtained from a rock which forms a lofty natural pier on the ſouth ſhore of the iſland. The pedeſtal of St. Cuthbert's croſs, anciently held in great veneration, and now called the *polting ſtone*, is ſituated a ſhort way to the eaſt. When a bride cannot ſtep the length of it, the ſuperſtitious reckon it ominous of future unhappineſs in the marriage ſtate. The pariſh church is a plain but ſpacious ſtructure, having ſemicircular arches on the one ſide and pointed ones on the other. The windows are long and narrow. The caſtle ſtands upon a lofty whin-ſtone rock on the ſouth-eaſt portion of the iſland. At the commencement of the civil wars it was garriſoned by the king's forces, but ſhortly after fell into the hands of the parliament. The Pretender attempted to obtain poſſeſſion of it in the year 1715. A detachment of invalids is now uſually ſtationed here. Hodgſon's Beauties of Northumberland, 8vo. 1811.

LINDO, a town, or rather the remains of a town, in the iſland of Rhodes, anciently called *Lindus*, the native place of Cleobulus, one of the ſeven wiſe men of Greece, and of Chares, who made or at leaſt began the famous coloſſus, conſecrated to the ſun, and the ſcite of a magnificent temple dedicated to Minerva. This temple is ſaid to have been built by Danaus, king of Egypt, on landing here in his flight from his own kingdom. A feſtival was celebrated here, not with bleſſings and prayers, but, as Lactantius ſays, with curſes and imprecations; inſomuch that if a good word eſcaped from any perſon preſent, it was deemed a bad omen, and the ceremony was begun anew. The veſtiges of this city, called *Lindo*, are ſeated in a hamlet nearly in the middle of the E. ſide of the iſland, and altogether peopled by Greeks; its harbour, though far from being ſpacious, is much frequented by the ſmall craft of the country; which there take in the commodities of the iſland and bring thither merchandiſe from other parts. Accordingly almoſt all the inhabitants of Lindo are addicted to commerce, or to the carrying trade of the neighbouring coaſts and iſlands; they navigate with ſmall faſt-ſailing veſſels conſtructed by themſelves, and to which they give greater ſolidity than the ſhips which come off the ſtocks of Rhodes, on account of government. A few Lindians alſo employ themſelves in rural labours, but as the part of the iſland which they inhabit is leſs capable of tillage than any other parts, on account of its ſtony ſoil, their culture principally conſiſts of plantations of vines, fig-trees, and ſuch others; 14 miles S.S.W. of Rhodes. N. lat. 36° 17′. E. long 27° 38′. Sonnini.

LINDON, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 60° 55′. E. long. 16° 57′.

LINDOW, a town of Brandenburg, in the Middle Mark; 33 miles N.N.W. of Berlin. N. lat. 52° 57′. E. long. 13 .—Alſo, a town of Brandenburg, in the Middle Mark; 8 miles S.S.W. of Franckfort on the Oder.

LINDSÆA, in *Botany*, a genus of ferns, ſo named by the late Mr. Dryander, after Mr. John Lindſay, "an aſſiduous and ſkillful botaniſt of Jamaica," author of a paper, printed in the Tranſactions of the Linnæan Soc. v. 2. 93, on the germination and raiſing of ferns from the ſeed; as well as of another paper, in the ſame vol. p. 313, concerning the raiſing of ſeveral other cryptogamic plants in the ſame manner. Dryandr. Tr. of Linn. Soc. v. 3. 39. Sm. Mem. de l'Acad. de Turin, v. 5. 413. t. 9. f. 4. Tracts on Nat. Hiſt. 242. t. 1. f. 4. Swartz. Fil. 118. Brown Prodr. Nov. Holl. v. 1. 156.—Claſs and order, *Cryptogamia Filices*. Nat. Ord. *Filices dorſiferæ*, Linn. Juſſ.

Gen. Ch. *Capſules* annulated, in continued, nearly marginal, lateral or terminal, lines. *Involucrum* ariſing from the ſurface of the leaf, membranous, continued, entire or ſlightly crenate, at length reflexed, permanent.

Eſſ. Ch. *Fructification* in continued, nearly marginal, lines. *Involucrum* from the ſurface of the leaf, continued, ſeparating at the ſide towards the margin.

Nine ſpecies are deſcribed in Mr. Dryander's original eſſay, to which five are added by Dr. Swartz, one by M. Labillardiere and one by Mr. Brown.

1. L. *ſagittata*. Dryandr. n. 1. (Adiantum ſagittatum; Aubl. Guian. 964. t. 366.)—Frond ſimple, arrow or heart-ſhaped, with a taper point.—Native of woods and fiſſures of rocks in Guiana. The *root* is creeping, bearing five or ſix *fronds* in a cluſter, near a ſpan high; the *ſtalks* black and ſhining; *leaf* ſmooth, with dichotomous veins all ſpringing from its baſe where the ſtalk is inſerted; line of fructification about a ſtraw's breadth from the edge.

2. L. *reniformis*. Dryandr. n. 2. Tr. of Linn. Soc. v. 3. t. 7. f. 1.—Frond ſimple, kidney-ſhaped, obtuſe.—Native of Guiana and Surinam.—Much like the laſt, of which we are inclined to ſuſpect it a variety.

3. L. *enſifolia*. Swartz n. 3.—Frond pinnate; leaflets alternate, ſword-ſhaped.—From the iſland of Mauritius. We have what anſwers to this character, from Madagaſcar; but if right, it is very nearly allied to the following.

4. L. *lanceolata*. Brown. n. 2. Labill. Nov. Holl. v. 2. 98. t. 248. f. 1.—Frond pinnate; leaflets alternate, linear-lanceolate, ſometimes pinnatifid; ſtalk ſquare.—Found by Labillardiere at Van Diemen's land; by Mr. Brown in the tropical part of New Holland. Each *leaflet* is about one and a half inch or two inches long, nearly ſeſſile. If the dichotomous form, and great diſtance of the lateral veins from each other, which are very remarkable characters in Labillardiere's plate, be correct, this ſpecies is eſſentially diſtinct from the laſt, whoſe veins compoſe an uniform ſort of network, interbranching with each other over the whole diſk of the leaf.

5. L. *grandifolia*. Frond pinnate; leaflets oppoſite, elliptic-lanceolate, pointed. Fructification half way between the rib and the margin.—Gathered in Malacca.—We know this merely from a pencil ſketch taken by the younger Linnæus, marked with the native country of the plant, and a note ſaying it "probably conſtitutes a new genus, of which Aublet's tab. 365 and 366, and an *Adiantum* of Smeathman's, are other ſpecies." This was perhaps written at ſir Joſ. Banks's; but if ſo, we cannot account for Mr. Dryander's having omitted this ſpecies, which appears to be one of the moſt remarkable of the whole number. The *frond* conſiſts of two pair of oppoſite, ſlightly ſtalked, leaflets, three or four inches long, with a terminal one ſtill longer. A line of fructification lies midway between the rib and the margin, on each ſide of the former; but none of the lines extend either to the baſe or the ſummit, by near an inch.

6. L. *linearis*. Swartz n. 4. 318. t. 3. f. 3.—Frond pinnate, linear; leaflets very numerous, fan-ſhaped, finely crenate and fructifying at their outer edge.—Native of various parts of New Holland. We have it from Port Jackſon. About a foot high, with a dark poliſhed *ſtalk*, tapering and zigzag at the baſe. The *leaflets* are imperfectly oppoſite, deflexed, ſmall, broad and very ſhort, ſo as to give a remarkable narrowneſs to the ſhape of the whole frond.

7. L. *falcata*. Dryander. n. 3. t. 7. f. 2.—Frond pinnate; leaflets ſomewhat creſcent-ſhaped, entire, wavy.—Gathered by Aublet in Guiana.—About a foot high, with ſeveral

pair of rather cloſe *leaflets*, each about an inch long, ſlightly falcate backward, wavy at their upper edge, along which runs the line of fructification. The terminal *leaflet* is irregularly ſhaped

8. L. *heterophylla*. Dryandr. n. 4. t. 8. f. 1. – Frond pinnate; leaflets entire or ſerrated; the lower ones ſomewhat rhomboid-lanceolate, pointed; the upper rhomboid and very obtuſe; the uppermoſt confluent.—Gathered by Mr. Robertſon at Malacca. A ſpan high, with very various, ſlightly diſtant *leaflets*, the longeſt of which meaſure ſcarcely an inch.

9. L. *cultrata*. Swartz. n. 7. (Adiantum cultratum; Willd. Phytogr. faſc. 1. 14. t. 10. f. 2.). Frond pinnate; leaflets oblong, obtuſe, wavy at their upper margin; the terminal one elongated jagged. Native of the coaſt of Malabar.—*Frond* about five inches high, with a green *ſtalk*, 10 or 12 pair of alternate, ſtalked, horizontal *leaflets*, and a ſingularly jagged, elongated, upright terminal one.

10. L. *flabellulata*. Dryandr. n. 5. t. 8. f. 2.—Frond pinnate; leaflets fan-ſhaped, finely toothed; the lower ones of the old plants compound. Native of China, Macao, and Sumatra.—The *leaflets* are almoſt ſemicircular at their fructifying edge, which ſtands outwards, not uppermoſt.

11. L. *trapeziformis*. Dryandr. n. 6. t. 9. – Frond doubly pinnate; leaflets quadrangular, abrupt; the lowermoſt fanſhaped. – Gathered in Grenada by Smeathman; ſee our n. 5. —A large and handſome fern, each branch of whoſe *frond* conſiſts of above a dozen pair of oblong quadrangular leaflets, fructifying at their upper and outer margins.

12. L *guianenſis*. Dryandr. n. 7. (Adiantum guianenſe; Aubl. Guian. 962. t. 365.)—Frond doubly pinnate; its branches ſpreading, tapering; leaflets crowded; the lower lunate; middle ones ſquare; upper fan-ſhaped.- Gathered by Aublet at the bottoms of little hills in the foreſts of Guiana. This is a very handſome *fern*, two or three feet high, with a longiſh *ſtalk*, and about ſix pair of nearly oppoſite, tapering, widely ſpreading *branches*, each compoſed of innumerable, crowded, light green *leaflets*, more or leſs rounded in their upper or fore-part, which is bordered with a broad brown line of fructification.

13. L. *ſtricta*. Dryandr. n. 8. Swartz Ind. Occ. 1722. (Adiantum ſtrictum; Swartz Prodr. 135.)—Frond doubly pinnate; branches erect, contracted; leaflets trapeziform.- Native of Jamaica, Porto Rico, and Panama. —No figure of this ſpecies has yet appeared.

14. L. *media*. Brown n. 3. Frond doubly pinnate; deltoid; leaflets obovato-rhomboid, coriaceous; the lower ones lobed; the reſt entire; with a ſolitary uninterrupted line of fructification at the fore edge; the barren ones ſerrated at the top; ſtalk ſquare. Gathered by Mr. Brown in the tropical part of New Holland

15. L. *trichomanoides*. Dryandr. n. 9. t. 11.—Frond doubly pinnate; leaflets membranous, linear-clubſhaped, abrupt.—Gathered at Duſky bay, New Zeeland, by Mr. A. Menzies. A delicate ſpecies, a ſpan high, with ſlender creeping downy *roots*, and ſmooth brown *ſtalks*. The *leaflets* vary in ſize and breadth, but are nearly wedge-ſhaped, decurrent and confluent, of a light green colour and ſomewhat membranous texture, ſo as much to reſemble a *Trichomanes* or *Hymenophyllum*; their ſummit abrupt, crenate or jagged. Line of *fructification* ſometimes very ſhort; the *involucrum* broadiſh, ſcarcely ever reflexed, but finally deciduous, along with the capſules.

16. L. *tenera*. Dryandr. n. 10. t. 10.—Frond triply pinnate, triangular; leaflets obovate, ſomewhat rhomboid, cut.—Native of the Eaſt Indies; ſent to ſir Joſeph Banks by the Moravian miſſionaries from the iſland of Nicobar. It appears to us as truly pinnate as any of the others, rather than pinnatifid, though the ultimate diviſions, or *leaflets*, are decurrent; theſe are broader and more rounded than in the laſt, as well as lobed or cut.

17. L. *microphylla*. Swartz n. 14. 319.—Frond lanceolate, triply pinnate; leaflets wedge-ſhaped, dilated and crenate at the top. Gathered near Port Jackſon, New South Wales, by Dr. White. This elegant ſpecies is a foot and a half, or more, in height; the whole *frond* of a narrow lanceolate figure, with ſlender, lax, pinnate branches, and ſmall, light green dotted *leaflets*, which are wedge-ſhaped, tapering at the baſe, always crenate at the ſummit, as is alſo the *involucrum*. Every *leaflet* is ſuddenly dilated oppoſite to each end of the fructifying line.

The three laſt ſpecies are naturally allied to the genus *Davallia* (ſee that article), with which they agree as to habit, and occaſionally even in the ſhort round figure of their fructification and involucrum, which in general however are continued in a ſubmarginal line.

LINDSAY, JOHN, in *Biography*, a learned nonjuring divine, who was educated at St. Mary-Hall, Oxford. He had a congregation in London, among whom he regularly officiated, and was employed by Mr. Bowyer as a corrector of the preſs. He tranſlated Maſon's "Vindication of the Church of England;" and wrote "A Short Hiſtory of the Royal Succeſſion;" and "Remarks on Whiſton's Scripture Politics." He died in 1768, aged 82.

LINDSAY, *Sir* **DAVID**, a Scotch poet, was a native of the county of Fife, and educated at the univerſity of St. Andrews. He was at the battle of Pavia, and on his return to Scotland James V. appointed him maſter of the herald's office. He wrote ſeveral poems, ſome of which have been printed, particularly his Satires on the Clergy. He died in 1557, aged 61. There was another of this family named David likewiſe, who was born about the year 1527: he was a zealous promoter of the reformation, and died in 1592. He wrote the Hiſtory of Scotland from 1437 to 1542.

LINDSEY, THEOPHILUS, was born at Middlewich, in Cheſhire, June 20th, 1723, old ſtyle. His father, Mr. Robert Lindſey, was an opulent proprietor of the ſalt-works in that neighbourhood; his mother's name was Spencer, a younger branch of the Spencer family, in the county of Buckingham. Theophilus was the ſecond of three children, and ſo named after his godfather, Theophilus, earl of Huntingdon. He received the rudiments of grammar learning at Middlewich, and from his early attachment to books, and the habitual ſeriouſneſs of his mind, he was intended by his mother for the church. He loſt ſome time by a change of ſchools, till he was put under the care of Mr. Barnard of the free-ſchool of Leeds, under whom he made a rapid progreſs in claſſical learning. At the age of eighteen he was admitted of St. John's college, Cambridge, where, by exemplary diligence and moral conduct, he obtained the entire approbation of his tutors. As ſoon as he had finiſhed his ſtudies at college, taken his firſt degree, and had been admitted to deacon's orders, he was nominated by ſir George Wheeler to a chapel in Spital ſquare, London. Soon after this, he was, by the recommendation of the earl of Huntingdon, appointed domeſtic chaplain to Algernon, duke of Somerſet. The duke, from a great regard for his merit, determined to procure him a high rank in the church, but an early death deprived Mr. Lindſey of his illuſtrious patron. In 1754, he accompanied the preſent duke of Northumberland to the continent, and on his return he ſupplied, for ſome time, the temporary vacancy of a good living in the north of England, called Kirkby-Wiſk: here he became acquainted with Mr. archdeacon Blackburne, and in 1760 married his daughter-in-law. From Kirkby Mr. Lindſey went to Piddletown, in Dorſetſhire, having been preſented to the living of that place by the earl of Huntingdon: this, through the intereſt of the ſame patron, he exchanged, in 1764, for the vicarage of Catterick, in Yorkſhire. Here he reſided nearly ten years, an exemplary pattern of a primitive and conſcientious paſtor, highly reſpected and beloved by the people committed to his charge. Beſides his various and important duties as a pariſh clergyman, Mr. Lindſey was ever alive, and heartily active, in every cauſe in which the principles of truth and right reaſon were concerned. We accordingly find him, in 1771, zealouſly co-operating with Mr. archdeacon Blackburne, Dr. John Jebb, Mr. Wyvil, and others, in endeavouring to obtain relief in matters of ſubſcription to the thirty-nine articles: the object of theſe gentlemen was ſimply this, that the clergy of the eſtabliſhed church might be permitted to hold their preferments upon condition of merely ſubſcribing their belief of the holy ſcriptures, inſtead of the thirty-nine articles. The queſtion was brought before the houſe of commons in 1772, but after a very animated diſcuſſion, it was loſt by a great majority. Conſidering the iſſue of this debate as an abſolute diſappointment and refuſal of all their juſt and righteous demands, he began to conſider what courſe he ſhould take to ſatisfy his conſcience, and in a ſhort time explicitly avowed his intentions of reſigning his living. He had, probably, for ſome years, had doubts with reſpect to the doctrine of the Trinity, and other leading topics of the eſtabliſhed faith, and early in the year 1773 an anonymous writer, under the ſignature of Lælius, ſtarted the ſubject of the impropriety of perſons remaining in the church who could not conſcientiouſly conform to her principles: to this Mr. Lindſey, in a letter to a friend, moſt feelingly alludes; "The ſubject of Lælius's laſt letter may give one many a pang. I cannot ſay that I have been for many years a day free from uneaſineſs about it." In the following November he wrote to the prelate of his dioceſe, informing him of his intention to quit the church, and ſignifying, that in a few days he ſhould tranſmit to him his deed of reſignation. The biſhop endeavoured to perſuade him to remain at his poſt, but he had made up his mind that duty required the ſacrifice, and he was reſolved to bear the conſequences. When the act was done, he ſaid he felt himſelf delivered from a load which had long lain heavy upon him, and at times nearly overwhelmed him. Previouſly to his quitting Catterick, Mr. Lindſey delivered a farewell addreſs to his pariſhioners, in which he ſtated his motives for quitting them in a ſimple and very affecting manner, pointing out the reaſons why he could no longer conduct, nor join in their worſhip, without the guilt of continual inſincerity before God, and endangering the loſs of his favour for ever. He left Catterick about the middle of December, and after viſiting ſome friends in different parts of the country, he arrived in London in January 1774, where he met with friends, who zealouſly patronized the idea which he entertained of opening a place of worſhip, devoted entirely to Unitarian principles. A large room was at firſt fitted up for the purpoſe in Eſſex-ſtreet in the Strand, which, after overcoming ſome legal obſtacles, thrown out by the magiſtrates in the way of regiſtering it, was opened April 17, 1774. The ſervice of the place was conducted according to the plan of a liturgy which had been altered from that uſed in the eſtabliſhed church by the late Dr. Samuel Clarke, rector of St. James's church, Piccadilly, London. Mr. Lindſey publiſhed the ſermon which he preached on the opening of his chapel, to which was added an account of the liturgy made uſe of. About the ſame time he publiſhed his "Apology," of which ſeveral editions were called for in the courſe of a few years. This was followed by a ſtill larger volume, entitled "A Sequel to the Apology," which was intended as a reply to his various opponents, and likewiſe to vindicate and eſtabliſh the leading doctrines which he profeſſed, and on account of which he had given up his preferment in the church. This work was publiſhed in 1776, and in 1778 he was enabled, by the aſſiſtance of his friends, to build the chapel of Eſſex-ſtreet, and to purchaſe the ground on which it ſtands. Till the ſummer of 1793, Mr. Lindſey, with the aid of his friend the Rev. Dr. Diſney, conducted the ſervices of the place, upon ſtrict Unitarian principles, to a reſpectable and numerous congregation. He then reſigned the whole into the hands of his very able coadjutor, notwithſtanding the earneſt wiſhes of his hearers that he ſhould ſtill continue a part of the ſervices. Though he had quitted the duties of the pulpit, he continued to labour in the cauſe, by his publications, till he had attained his eightieth year. In 1802 he publiſhed his laſt work, entitled "Converſations on the Divine Government, ſhewing that every Thing is from God, and for good to all." The object of this piece, which has been reprinted for general circulation by a ſociety for promoting Chriſtian knowledge, &c. is to vindicate the Creator from thoſe gloomy notions which are too often attached to his providence, and to ſhew that the government of the world is the wiſeſt that could have been adopted, and that afflictions and apparent evils are permitted for the general good. From this principle Mr. Lindſey derived conſolation through life, and upon it he acted in every difficult and trying ſcene. On his death bed he ſpoke of his ſufferings with perfect patience and meekneſs, and when reminded, by a friend, that he doubtleſs was enabled to bear them with ſo much fortitude in the recollection of his favourite maxim, that "Whatever is, is right;" no, ſaid the dying Chriſtian, with animation that lighted up his countenance, "Whatever is, is beſt." This was the laſt ſentence which he was able diſtinctly to articulate: he died November 3, 1808. Beſides the works already referred to, he publiſhed two diſſertations; 1. On the Preface to St. John's Goſpel; 2. On praying to Chriſt: "An Hiſtorical View of the State of the Unitarian Doctrine and Worſhip from the Reformation to our own Times;" and ſeveral other pieces. Among controverſial writers Mr. Lindſey takes a very reſpectable place, as his "Vindiciæ Prieſtleianæ," and his "Examination of Mr. Robinſon's Plea for the Divinity of Chriſt," will ſhew. In every character of life which this excellent man ſuſtained, he acted his part with honour and integrity, and for his exertions in the cauſe of truth and rational Chriſtianity, whatever may be thought of his peculiar opinions, many will riſe up and call him bleſſed. Others, equally devout, equally humble, equally perſevering, will be forgotten when the name of Theophilus Lindſey ſhall be held in veneration, becauſe to humility, piety, and perſeverance, he added a courageous avowal of what he believed to be the truth: he bore public teſtimony, in oppoſition to the penal laws, in matters of faith, that ſtill exiſt on our ſtatute-book, to the unity of God at the hazard of all. Two volumes of his ſermons have been publiſhed ſince his death. Monthly Mag. Dec. 1808.

LINDUM, in *Ancient Geography*, a town of Britain, in the country of the Coretani, which by the 5th Iter of Antonine is ſituated between Cauſennæ or Ancaſter, and Segelocum or Littleborough. This is univerſally agreed to be Lincoln, which was a Roman colony, and a place of great importance in ancient times. Baxter, without ſufficient authority, contends that Lindum was the Lendinium in which ſo many of the Romans were ſlain by the Britons in their great revolt under Boadicea. See LINCOLN.

LINDUM was alſo the name of a place in the country of the Dumnii; which, in both the ſound and ſignification of the name, bears ſo great a reſemblance to Linlithgow, that it is moſt probably the ſame place, though its ſituation does not exactly agree with that aſſigned by Ptolemy, who is far from being correct in this particular,

LINDY, in *Geography*, a town of Africa, in Querimba, S. lat. 9° 58′. E. long. 41° 4′.

LINE, in *Geometry*, a quantity extended in length only, without either breadth or thickneſs.

A line is ſuppoſed to be formed by the flux or motion of a point; and is to be conceived as the termination or limit of a ſurface, and not as a part of that ſurface, however ſmall.

There are two kinds of lines; *viz. right* lines, and *curve* lines.

If the point A moves towards B (*Pl.* X. *Geometry*, *fig.* 1.) by its motion it deſcribes a line: and this, if the point go the neareſt way towards B, will be a right or ſtraight line, whoſe definition therefore is the neareſt or ſhorteſt diſtance between any two points, or a line, all whoſe points tend the ſame way. If the point go any way about, as in the lines A C B, or A *c* B, it will trace out either a crooked line, as the upper A *c* B; or elſe two or more ſtraight ones, as in the lower A C, C B.

Right lines are all of the ſame ſpecies: but curves are of an infinite number of different ſpecies; we may conceive as many as there are different compound motions, or as many as there may be different ratios between their ordinates and abſciſſas.

Curve lines are uſually divided into *geometrical* and *mechanical*. The former are thoſe which may be found exactly and ſecurely in all their points. (See Geometrical *line*.) The latter are thoſe, ſome or all of whoſe points are not to be found preciſely, but only tentatively, or nearly.

Accordingly, Deſcartes and his followers define *geometrical* lines, thoſe which may be expreſſed by an algebraic equation of a determinate degree; which equation is alſo called *locus*.

The ſame perſons define *mechanical* lines thoſe which cannot be expreſſed by an equation of a determinate degree. Others, conſidering that thoſe called by Deſcartes *mechanical* lines, notwithſtanding their not being of a determinate degree, are not leſs preciſe and exact, and conſequently not leſs geometrical than the others; it being this preciſion which conſtitutes the geometricity of the line: for this reaſon, chooſe rather to call thoſe lines which are reducible to a determinate degree, *algebraical* lines; and thoſe which are not, *tranſcendental* lines.

Lines are alſo divided into thoſe of the *firſt order*, *ſecond order*, *third order*, &c. See Curve.

Sir Iſaac Newton enumerated ſeventy-two lines of the third order, and Mr. Stirling found four more; ſince that Mr. Stone has found two others, which had eſcaped ſir Iſaac and Mr. Stirling. The two ſpecies added are to be reckoned among the hyperbolico-parabolical curves. Enumer. Lin. Tert. Ordin. Linea. Tert. Ordin. Neutonianæ, Oxon. 1717. 8vo. Phil. Tranſ. N° 456. § 6. See Curve.

Lines, conſidered as to their poſitions, are either *parallel*, *perpendicular*, or *oblique;* the conſtruction and properties of each whereof, ſee under Parallel, Perpendicular, &c.

Euclid's ſecond book treats moſtly of lines, and of the effects of their being divided, and again multiplied into one another.

Lines, *Algebraic*, are divided into different orders, according to the degree of their equations. Theſe degrees are eſtimated, as in determined equations, by the degree of the higheſt term of the equation.

Thus $a + by + cx = 0$, is a general equation, expreſſing the nature of lines of the firſt order, or of ſtraight lines.

The equation $a + by + cx + dyy + exy + fxx = 0$, repreſents the lines of the ſecond order; that is, the conic ſections, and the circle, which is one of them.

And the equation $a + by + cx + dyy + exy + fxx + gy^3 + hxyy + ix^2y + lx^3 = 0$, expreſſes in general the lines of the third order. And the lines of the fourth and higher orders may be expreſſed in the like manner. See Cramer Introd. à l'Analyſe des Lignes Courbes, p. 52, ſeq. Mr. Cramer uſes the terms *lines* of the ſecond, third, fourth, &c. order, and *curve* of the ſecond, third, fourth, &c. order, indifferently. Sir Iſaac Newton has made a diſtinction, according to him. See Curve.

Lines, *circular*, *converging*, *diverging*, *generating*, *heliſpherical*, *hyperbolic*, *logiſtic*, *magnetical*, *normal*, *proportional*, *quadrature*, *reciprocal*, *robervalian*, and *vertical*. See the reſpective adjectives.

Line *of the Apſides*, in *Aſtronomy*, is the line which joins the apſides; or it is the greater axis of the orbit of a planet.

Line, *Fiducial*, the line or ruler which paſſes through the middle of an aſtrolabe, or the like inſtrument; and on which the ſights are fitted; otherwiſe called *alhidade*, *index*, *dioptra*, and *mediclinium*.

Line, *Horizontal*, a line parallel to the horizon.

Lines, *Iſochronal* and *Meridian*. See the adjectives.

Line *of the Nodes*, in *Aſtronomy*, is the line which joins the nodes of the orbit of a planet, or the common ſection of the plane of the orbit with the plane of the ecliptic.

Line, *Horizontal*, in *Dialling*, is the common ſection of the horizon, and the dial-plate.

Lines, *Horary*, or *Hour-lines*, are the common interſections of the hour-circles of the ſphere, with the plane of the dial. See Horary, and Hour-*circles*.

Line, *Subſtylar*. See Substylar.

Line, *Equinoctial*, is the common interſection of the equinoctial, and the plane of the dial.

Line, *Contingent*. See Contingent.

Lines, *Dialling* and *Meridian*. See the reſpective adjectives.

Line, in *Fencing*, is that part of the body directly oppoſite to the enemy, wherein the ſhoulders, the right arm, and the ſword, ought always to be found; and wherein are alſo to be placed the two feet, at the diſtance of eighteen inches from each other.

In this ſenſe, a man is ſaid to be in his line, to go out of his line, &c.

Line, in *Fortification*, is ſometimes taken for a ditch, bordered with its parapet; and ſometimes for a row of gabions, or ſacks of earth, extended lengthwiſe on the ground, to ſerve as a ſhelter againſt the enemy's fire.

When the trenches were carried on within thirty paces of the glacis, they drew two lines, one on the right, and the other on the left, for a place of arms.

For the difference between trenches or approaches, and lines, ſee Intrenchment.

Lines are generally made to ſhut up an avenue or entrance to ſome place; the ſides of that entrance being covered by rivers, woods, mountains, moraſſes, or other obſtructions, not eaſy to be paſſed over by an army. When they are conſtructed in an open country, they are carried round the place to be defended, and reſemble the lines ſurrounding a camp, called lines of circumvallation. Lines are likewiſe thrown up to ſtop the progreſs of an army; but the term is moſt commonly applied to the line which covers a paſs that can only be attacked in front. For conſtructing ſuch a line in the place moſt convenient for the purpoſe, let a rope be run quite acroſs the way along the intended place of the line, pegging it to the ground at the diſtance of every four or five yards; and at the diſtance of about ten or twelve feet before the line, towards the enemy, let ſuch another line or row of ſtakes be carried in a poſition parallel to the firſt rope. When the labourers are properly ranged within theſe limits, let them dig up the earth in this breadth, and throw it on the other ſide of the firſt rope, until a bank of about five or ſix feet thick, and ſix or ſeven feet high, be raiſed, ſloping the ſides according to the declivity neceſſary for the earth's rolling naturally down the bank; and let the digging be continued till the ditch is about five or ſix feet deep, the breadth of the bottom being about one-third of the breadth ſtaked out at top: the bank may be rendered more firm by being trod or rammed down. Let the inner ſide of the bank be pared with the ſpade into ſuch a ſlope, as a man ſtanding upright may eaſily touch with his arm extended ſtraight before him; and at the foot of this bank, let a foot-bank or ſtep be raiſed, of ſuch a height, as a man ſtanding on it may eaſily fire his muſket over the bank, or let it be about four feet and a half lower than the top of the bank or breaſt-work. A gentle ſlope may alſo be made to the foot-bank, that the troops may more eaſily aſcend it; and let the crown or top of the breaſt-work be ſloped ſo, that a muſket laid flat on it may ſtrike the ground with its ſhot, about five or ſix feet beyond the ditch. The bank or breaſt-work will, in this caſe, ſecure the troops behind the lines from the enemy's fire; and when they ſtand on the foot-bank, they are more than two-thirds covered, and, conſequently, the troops within may make three of their ſhots tell for one of the enemy; and by going off the foot-bank, they may be quite covered, while they load again; ſo that with this advantage, they are in no great danger of being forced from the lines, unleſs the enemy are greatly ſuperior in number and cannon.

The following Table ſhews the dimenſions of lines commonly conſtructed, and the rate of expence attending the conſtruction of them.

Breaſt-Work.			Ditch.			Expence.	
Thickneſs at top.	Height within.	Height without.	Upper breadth.	Lower breadth.	Depth.	Solid Content.	Days' works.
Feet.	Feet.	Feet.	Feet.	Feet.	Feet.	Feet.	
4	$7\frac{1}{2}$	6	8	$2\frac{2}{3}$	5	$4\frac{2}{3}$	1
5	$7\frac{1}{2}$	6	10	$3\frac{1}{4}$	$5\frac{1}{2}$	$6\frac{1}{12}$	$1\frac{1}{2}$
6	$7\frac{1}{2}$	6	12	4	6	8	2
7	$7\frac{1}{2}$	6	14	$4\frac{2}{3}$	$6\frac{1}{2}$	10	$2\frac{1}{2}$
8	$7\frac{1}{2}$	6	16	$5\frac{1}{2}$	7	12	3
9	$7\frac{1}{2}$	6	18	6	$7\frac{1}{2}$	15	$3\frac{1}{2}$

The day's work here is for one yard in length; and in the firſt, a hundred men will complete a hundred yards in length of this kind of lines in one day; two hundred men in half a day, &c. The lines above deſcribed are called temporary lines, and chiefly ſerve a preſent emergency. When lines are thrown up at leiſure, and deſigned for longer duration, then the ditch is uſually eighteen feet broad at top, ſeven or eight feet deep, and the ſides of the ditch are ſloped, ſo as to leave only ſix feet breadth at bottom; the breaſt-work, or parapet, is about ſeven feet thick on the top or crown, and ſeven or eight feet high. The heights, depths, and breadths, of the ſeveral parts of a line well deſigned and finiſhed, are exhibited in *Plate* VI. *Fortification, fig.* 3, in which I L repreſents the ground line, or ſurface of the place; A B the breadth of the ditch at the top; C D its breadth at the bottom; F A C the ſlope or ſcarp of the parapet and ditch; D B K the counterſcarp; E F the top or crown of the parapet or breaſt-work; E G the inner ſlope of the parapet; H G the top of the foot-bank; H I the ſlope of the foot-bank; and B K L a ſmall ſloping bank, called the glacis. This ſection or profile may be drawn, by laying off in the ground-line, from any ſcale of equal parts, the diſtances $1\,a = 6$ feet, $ab = 4$, $bc = 1\frac{1}{2}$, $cd = 7$, $d\mathrm{A} = 4\frac{1}{2}$, $\mathrm{A}f = 6$, $fg = 6$, $g\mathrm{B} = 6$, and $\mathrm{BL} = 5$ feet. Through *a*, *b*, *c*, *d*, *f*, *g*, B, draw lines perpendicular to I L. Make $a\mathrm{H} = 2\frac{1}{2}$ feet $= b\mathrm{G}$, $c\mathrm{E} = 7$ feet, $d\mathrm{F} = 6$, $f\mathrm{C} = 8$ feet $= g\mathrm{D}$. Draw I H, H G, G E, E F, F A C, C D, and D B, which continue, till it meets the line F L, and the profile is conſtructed.

When lines are made to cover a camp, or a large tract of land, where a conſiderable body of troops is poſted, the work is not made in one ſtraight, or uniformly bending line; but at certain diſtances, the lines project in ſaliant angles, called redents, redans, or flankers, towards the enemy. The diſtance between theſe angles is uſually between the limits of two hundred and two hundred and ſixty yards; the ordinary flight of a muſket-ball, point-blank, being generally within thoſe limits; although muſkets, a little elevated, will do effectual ſervice at the diſtance of three hundred and ſixty yards. In *Plate* VI. *Fortification, fig.* 4, are ſhewn the forms of the uſual lines, where the figures C A B, *c a b*, are the redents or flankers; A C, A B, *a c*, *a b*, the faces; C B, *c b*, the gorges; A D, *a d*, the capitals; B *b* the curtin; and the angles C A B, *c a b*, the ſaliant or flanked angles. The diſtance of the ſaliant angles is about two hundred and forty yards at a mean; the length of the capital is uſually between forty and fifty yards, and the length of the gorges is alſo about ſixty or ſeventy yards.

To make a plan of lines with redents; draw the line E E E E, &c. (*Plate* VI. *Fortification, fig.* 5,) in ſuch a manner, that, wherever there is a bend or angle, it may be either at once, twice, or thrice, &c. the length of about two hundred and forty yards from one another; ſo that there may be a redent where there is an angle. In this line, lay off the diſtance of two hundred and forty yards from E to E, E to E, &c. reckoning from the bends towards each end, whether it happens that the line will or will not be exactly meaſured by a repetition of the two hundred and forty yards. At each point, E, draw the capital E F in a perpendicular poſition to the direction of the line in that point, and make the capitals about forty or fifty yards long. On each ſide of E, take the half gorges E G, E G, each of about thirty or thirty-five yards, and draw the faces F G, F G; and thus the out-line, or maſter-line, of the curtins and redents is formed. Parallel to each curtin and face draw lines, within, at the diſtances from the maſter-line of ſeven feet, eight feet, twelve feet, and eighteen feet; then the breadth of ſeven feet repreſents the plan of the parapet, that of one foot its inner ſlope, that of four feet the top of the foot-bank, and that of ſix feet the foot-bank ſlope. On the outſide of the maſter-line, draw lines at the diſtance of $10\frac{1}{2}$, $16\frac{1}{2}$, and $22\frac{1}{2}$ feet parallel to each curtin and face; and theſe will repreſent the plans of the ſcarp, ditch, and counterſcarp; obſerving that the ſaliant angles of the counterſcarp are rounded before the angles of the redents. A plan of this kind formed from a ſmall ſcale, as of twenty yards to an inch, is uſually repreſented by four parallel lines; one without the maſter-line, repreſenting the counterſcarp or out-line of the ditch, and two within, repreſenting the breadths of the parapet of the foot-bank. In ſome caſes, a ſhort line is haſtily formed by a number of *chevaux de friſe* chained together; and in countries abounding with wood, a line may be formed by laying, in a poſition pointing to the enemy, the ſtems of trees and their larger branches, piled on one another to a ſufficient height, and the interſtices filled with earth; ſuch a work is called an *abbatis*. See Robertſon's Marine Fort. p. 2, &c.

LINE, *Fundamental*, is the firſt line drawn for the plan of a place, and which ſhews its area.

LINE, *Capital*, in *Fortification*. See CAPITAL.

LINE, *Central*, is that drawn from the angle of the centre, to that of the baſtion.

LINE *of Defence*. See DEFENCE.

LINE *of Defence fichant*. See DEFENCE.

LINE *of Defence razant*. See DEFENCE.

LINE *of Approach*, or *Attack*, ſignifies the work which the beſiegers carry on under covert, to gain the moat, and the body of the place. See APPROACHES.

LINE *of Counter-approach*. See COUNTER-*approach*. See *Plate* VI. *Fortification*, *fig.* 6.

LINE *of Circumvallation*, is a line or trench cut by the beſiegers, within cannon-ſhot of the place, which ranges round their camp, and ſecures their quarters againſt any relief to be brought to the beſieged. See CIRCUMVALLATION.

LINE *of Contravallation*, is a ditch bordered with a parapet, which ſerves to cover the beſiegers on the ſide of the place, and to ſtop the ſallies of the garriſon. See CONTRAVALLATION.

LINES *of Communication*, are thoſe which run from one work to another. See *Plate* VI. *Fortification*, *fig.* 7. See alſo COMMUNICATION. But

The LINE *of Communication*, more eſpecially ſo called, is a continued trench, with which a circumvallation, or contravallation is ſurrounded; and which maintains a communication with all its forts, redoubts, and tenailles.

LINE *of the Baſe*, is a right line, which joins the points of the two neareſt baſtions.

To LINE *a Work*, ſignifies to face it, chiefly with brick or ſtone; *e. gr.* to ſtrengthen a rampart with a firm wall, or to encompaſs a parapet or moat with good turf, &c.

LINE, *Indented*, in *Fortification*. See REDENS.

LINES, among *Fowlers*, are uſed to expreſs the ſtrings by which they catch birds. The large and ſmall land birds are taken by them with equal eaſe, and ſometimes the water-fowl.

Theſe lines are made of long and ſmall cords, knotted in different places, and containing in length as many fathom as the places where they are to be laid require. Plovers, and the larger wild-fowl, are very conveniently taken by them. When theſe ſtrings are to be uſed, they muſt be limed with the ſtrongeſt bird-lime that can be got, and then coming to their haunts before the evening flights, that is, before ſun-ſet; or, for the morning flights, at leaſt two hours before day, the ſportſman is to carry a parcel of ſmall ſticks, each about two feet long, and ſharpened at both ends, but having a little ſlit at one end like a fork. The plain end of each ſtick is to be ſtuck into the ground, in ſuch a manner, that the ſtick ſtanding aſlant, its upper, or forked end, may be about a foot and a half from the ſurface. The limed ſtrings are then to be carried along all theſe ſticks, in different rows, ſome higher than others. Every row of the ſticks is thus to be filled, and the whole haunt covered with the lines. The plover, and other birds that fly low, when they come to their haunts, fly directly in amongſt the ſtrings, and are taken in great numbers; the whole flight coming in at once, and covering all the place, ſo that thoſe which are not yet alighted, have no opportunity of ſeeing the diſtreſs of their companions. There is no need for the ſportſman to be conſtantly upon the watch for the taking of the birds; for when once they are taken they cannot looſen themſelves, ſo that he may come and take them up at his own time. The water-fowl may be eaſily taken, in the ſame manner, by obſerving their haunts, and ſtretching theſe lines, in ſeveral rows, acroſs the brook, or river, ſome higher, and ſome lower, the loweſt lying almoſt at the edge of the water. Theſe muſt never be uſed on moonlight nights on the occaſion; for the ſhadow of the ſtrings in the water will then fright them away.

LINE, in *Genealogy*, is a ſeries of ſucceſſion or relations in various degrees, all deſcending from the ſame common father.

LINE, *Direct*, is that which goes from father to ſon; which is the order of aſcendants and deſcendants. See DIRECT.

LINE, *Collateral*, is the order of thoſe who deſcend from ſome common father, related to the former, but out of the line of aſcendants and deſcendants. In this are placed uncles, aunts, couſins, nephews, &c. See COLLATERAL. See alſo CONSANGUINITY and DESCENT.

LINE, in *Geography* and *Navigation*, is uſed by way of eminence for the equator or equinoctial line.

The line in the heavens is a circle deſcribed by the ſun in his courſe on the 20th day of March, and the 23d of September. The line on the earth is an imaginary circle anſwering to that in the heavens. It divides the earth from eaſt to weſt, into two equal parts, and is at an equal diſtance from the two poles; ſo that thoſe who live under the line have the poles always in their horizon.

The latitudes commence from the line.

The ſeamen have ſometimes practiſed the ceremony of chriſtening their freſh men, and paſſengers, the firſt time they croſs the line. See BAPTISM.

LINES, in *Heraldry*, the figures uſed in armories to divide the ſhield into different parts, and to compoſe different figures.

They are of different forms, and were it not for this, many arms would be one and the ſame, for a chief wavy differs from a plain chief, by the lines which compoſe them, and the heralds ſhew particular reaſons for all theſe different forms of lines.

Theſe lines, according to their forms and names, give denomination to the pieces or figures which they form, except the ſtraight or plain lines, which are carried evenly through the eſcutcheon, and are four, *viz.* the perpendicular line, the horizontal, the diagonal line dexter, and the diagonal line ſiniſter.

The crooked lines, which are carried unevenly through the eſcutcheon, riſing and falling, are theſe: firſt the ingrailed or engrailed, and inverted or invected; theſe, when repreſented together, are ſomewhat known the one from the other, being oppoſite to one another, both being made, as it were, of ſemicircles: the ingrailed with the points upward, the invected with the points downward. But this is not a ſufficient diſtinction: for ſuppoſe the ſpace between them which they form be a feſs, then the whole is only ingrailed, not invected; for the feſs ingrailed muſt have the points on both ſides turned towards the field, and the convex or gibboſe parts toward the feſs itſelf, and ſo of a bend, chevron, and other proper figures of heraldry; and if theſe be invected, then the convex parts of the lines are towards the field; but theſe lines are better diſtinguiſhed when placed by way of bordure, with the letters within a bordure ingrailed or invected.

Theſe two lines are more hard to be diſtinguiſhed, when the field is divided into two equal parts, of different colours, as parted per pale, parted per feſs, &c. Here we know not whether the line be ingrailed or invected, except we follow this rule, that the form of the line muſt be applied to the colour firſt named. The French terms for theſe two lines are, for the engrailed, *engrele*, and for the invected, *canele*; and the Latin writers expreſs ingrailed by *ingrediatus*, *imbricatus*, and *ſtriatus*, and the invected by the words *invertus* and *canaliculatus*.

The wavy, or waved line, is ſuch an one as is formed in repreſentation of the waves of the ſea, as parted per feſs wavy in arms and other waved lines, as the wavy bars all expreſs that the perſon got his honours by ſea ſervice.

Nebulee is another name of a line in heraldry: it expreſſes a clouded line; the French call it *nuance*, and the Latins *nebuloſa linea*. This alſo has been given to perſons who have been eminently ſkilled in navigation.

Crenele, or embattled lines, repreſent the battlements of a houſe, and are ſaid to repreſent in heraldry the ſkill in architecture, for which the firſt of the family was famous; they were alſo given ſometimes for eminent ſervices, in aſſaulting or defending caſtles in time of war, and ſometimes only as emblems of a houſe to expreſs a perſon who bore them being of a noble houſe or family; for of old, none were ſuffered to embattle their houſes but perſons of great diſtinction.

The Latin writers in heraldry uſe for the words *crenele*, the terms *pinnatus* and *pinnis aſperatus*, according to Uredus in his blazons, and Sylveſter Petra Sancta in his *murales pinnalee*.

There is another line of this kind in heraldry, which Leigh calls the battle-embattled line: this has one degree of embattling above another. When the upper points in this kind of line are repreſented ſharp, it is called campagne, as if the lines ending in points repreſented baſtions, or the outer works of cities and camps; and when the upper points are rounded, it is called crenele embattled arrondi.

The indented line is notched ſo at the edges, that it repreſents the teeth of a ſaw, and has its name from the Latin *dens*, a tooth, or from the law term *indenture*, a ſort of deed, the top of which is always notched like the teeth of a ſaw.

The dancette is another line, very much reſembling the indented line, but that it is always much ſmaller; it is therefore ſaid by the heralds to be the ſame in quality, but not in quantity. The dancette differs alſo from the indented line, in that it always conſiſts but of a few teeth, though never leſs than three, according to Mr. Holmes, in his Office of Armory; whereas the indented line has always a great many teeth. The French expreſs our indented line by the term *danche* or *dentille*; and the dancette, when it has but very few teeth, and thoſe very long, by the term *vivere*, which Meneſtrier takes to be the letter M, with its legs extended from ſide to ſide of the ſhield, becauſe many who carry a partition, or feſs, after that form, have the family name beginning with that letter. The Latin writers expreſs the term indented by *dentatus*, *indentatus*, and *denticulatus*; and when the teeth are very long, as in the dancette, they call them *dentes decumani*. See alſo NEBULY and RAGULED.

There are yet two other lines mentioned by the heraldry writers: the firſt is the *patee* or *dovetail* line, ſo called from its reſemblance to a ſort of joint uſed by our carpenters, in which one part goes alternately all the way down between two others; this is called by Morgan the inclave, or labelled line, becauſe the points, as they proceed from the ordinary, ſuch as the chief or feſs, repreſent not amiſs the points, or rather the ends of the labels. The other line is called *urdee* or *champagne* by Freſne; and by Upton, *vair*, becauſe its points are formed like pieces of the fur, called by heralds *vair*.

The two laſt of theſe are of very little uſe, the others are the common lines of arms, and are called the attributes or accidents of armorial figures which they form; and if any other lines are found in the figures or engravings of arms, which are not reducible to the one or the other of theſe, they are called *irregular*, and by the French heralds *clatte*. The knowledge and uſe of theſe forms of lines are neceſſary in the ſcience of heraldry to diſtinguiſh and difference many armorial bearings.

LINE, *Labelled*. See LABELLED.

LINE, *Lateral, linea lateralis*, in *Ichthyology*, a name given by naturaliſts to a line or ſtreak, with which many kinds of fiſh are marked, paſſing along their ſides. Few fiſh are without this line; but it is variouſly formed in the ſeveral kinds, and makes a very conſiderable article in their deſcription, if not in the diſtinction of the ſpecies. In ſome ſpecies it is made of a ſeries of little points, or holes, as appears to the eye; of this nature is the line in eels, &c. In ſome others it is formed of a ſort of duct, running along the centre of a great number of ſcales. This is its ſtructure in the generality of fiſhes.

This line, in various kinds of fiſh, varies alſo in regard to number, ſituation, figure, and other properties. In regard to number, there is no line obſerved in the ſyngnathi and petromyza, in almoſt all other fiſh, there is one on each ſide; and, finally, in ſome there are as it were two lines on each ſide: an inſtance of this we have in the ammodytæ. In regard to the ſituation, the differences are theſe: 1. In ſome it is near the back, as in the clupea, ſalmons, perch, and the like. 2. In others it is placed nearer the belly, and runs parallel with it, as in the cyprini. 3. In ſome it is placed in the centre of each ſide between the back and the belly, as in the caraſſius. 4. In ſome it is placed againſt the interſtices of the muſcles, or ſpina dorſalis, as in the muræna. And, 5. In ſome it is placed above the interſtices, as in the ammodytæ, &c. It has been ſuppoſed by many, that this *linea lateralis* was always parallel to the interſtices of muſcles; but this is evinced to be an erroneous opinion, by the obſervation of the perch and mackrel. In regard to the differences of figure, this line is in ſome ſtraight, as in the coregone, ſalmons, &c. 2. In others it is crooked, as in the cyprini, the perch, &c. and in the generality of fiſh is ſmooth to the touch, but in ſome it is rough and aculeated, as in the trachurus and pleuronecti. See *Anatomy of* FISHES.

LINE *of the Banquet*, in the *Manege*. See BANQUET.

LINE *of a Volt*. See SQUARE and VOLT.

LINE *of Direction*, in *Mechanics* and *Gunnery*. See DIRECTION.

LINE *of Gravitation of a heavy Body*, is a line drawn through its centre of gravity, and according to which it tends downwards.

LINE *of the ſwifteſt Deſcent of a heavy Body*. See DESCENT and CYCLOID.

LINE *of a Projectile*. See PROJECTILE.

LINES, in *Muſic*. Three, four, five, or ſix horizontal and parallel lines compoſe the ſtaff, upon which and between which all muſic, ſince the invention of counterpoint, has been written.

The ſtaff in canto fermo, or plain ſong, conſiſted only of a ſingle line, drawn through or between the points or dots of different elevation, to aid the prieſts in chanting: then two, three, and, finally, four lines compoſed the ſtaff for Gregorian notes in the miſſals and maſs books, in Roman Catholic churches; and theſe have never been increaſed. Secular muſic for the virginal, ſpinnet, harpſichord, and organ, from the time of queen Elizabeth to the end of the ſeventeenth century, was written on a ſtaff of ſix lines, both in the treble and the baſe. At the beginning of the laſt century, all muſic, except the tablature for the lute and guitar, began to be conſtantly written on and between five lines, called *ſpaces*, with the occaſional uſe of ſhort additional lines, for notes that go higher or lower than the regular ſtaff. The lines and ſpaces in all muſic are counted from the bottom, ſo that the loweſt is the firſt, the higheſt in canto fermo the fourth, and in figurative muſic the fifth. See STAVE, STAFF, PORTÉE, and RIGHE.

LINE, in *Inland Navigation*, is often uſed to expreſs the principal part of a canal, and thus to diſtinguiſh it from its branches.

LINES *of Deviation*, denote lines on the parliamentary plans of ſome canals, ſhewing the diſtances within a hill it is intended that the cutting of the canal ſhould be continued.

LINE, *Geometrical*, in *Perſpective*, is a right line drawn in any manner on the geometrical plane.

LINE, *Horizontal*. See HORIZONTAL.

LINE, *Terreſtrial*, or *Fundamental Line*, is a right line, wherein the geometrical plane, and that of the picture, or draught, interſect one another.

Such is the line N I (*Plate* I. *Perſpective*, *fig.* 3.) formed by the interſection of the geometrical plane L M, and the perſpective plane H L.

LINE *of the Front*, is any right line parallel to the terreſtrial line.

LINE, *Vertical*, is the common ſection of the vertical, and of the draught.

LINE, *Viſual*, is the line, or ray, imagined to paſs from the object to the eye.

LINE *of Station*, according to ſome writers, is the common ſection of the vertical and geometrical planes. Others mean by it, the perpendicular height of the eye above the geometrical plane; others, a line drawn on that plane, and perpendicular to the line expreſſing the height of the eye.

LINE, *Objective*, is any line drawn on the geometrical plane, whoſe repreſentation is ſought for in the draught or picture.

LINE *of Diſtance*. See DISTANCE.

LINES *on the plain Scale*, in *Trigonometry*, are the line of chords, line of ſines, line of tangents, line of ſecants, line of ſemi-tangents, line of leagues. The conſtruction and application of theſe lines, ſee under SCALE, SAILING, &c.

LINES *on Gunter's Scale*, are the line of numbers, line of artificial ſines, line of artificial tangents, line of artificial verſed ſines, line of artificial ſines of rhumbs, line of artificial tangents of the meridian line, and line of equal parts. The conſtruction and application of theſe lines, ſee under GUNTER'S *Scale*.

LINES *of the Sector*, are the line of equal parts, or line of lines; line of chords, line of ſines, line of tangents, line of ſecants, line of polygons, line of numbers, line of hours, line of latitudes, line of meridians, line of metals, line of ſolids, line of planes; the conſtruction and uſe of theſe, ſee SECTOR.

LINE, in the *Art of War*, is underſtood of the diſpoſition of an army, ranged in order of battle; with the front extended as far as may be, that the ſeveral corps of cavalry and infantry which compoſe it, may not be cut off or flanked by the enemy.

An army uſually conſiſts of three lines; the *firſt* is the front, van, or advance-guard; the main body forms the *ſecond*, in which is the general's poſt; the *third* is a reſerved body, or rear-guard. The term *line*, as expreſſing a military arrangement for battle, was not known till the 16th century. Before that period, when armies were ranged in order of battle upon three lines, theſe ſeveral lines were denominated in the manner above ſtated: but the terms advance-guard, main body, and rear-guard, are never uſed in modern times, except when an army is on its march: when drawn up for action, or in the field for review, they are denominated *lines*.

The ſecond line ſhould be about three hundred paces behind the firſt, and the reſerve at about five or ſix hundred paces behind the ſecond.

The artillery is likewiſe diſtributed along the front of the firſt line. The front line ſhould be ſtronger than the ſecond, that its ſhock may be more violent, and that, by having a greater front, it may more eaſily cloſe on the enemy's flanks.

Each line is ſo drawn up, that the wings or extremities always conſiſt of ſome ſquadrons of horſe, whoſe intervals are ſupported by infantry platoons. The battalions are poſted in the centre of each line; ſometimes they are intermixed with ſquadrons of horſe, when a conſiderable body of cavalry is attached to the army. The ſpace of ground which in each line ſeparates the different corps from one another, is always equal in extent to the front that is occupied by them. Theſe intervals are left in order to facilitate their ſeveral movements, and to enable them to charge the enemy without confuſion. It is a general rule, that the intervals or ſpaces which are between each battalion and ſquadron belonging to the *ſecond* line ſhould invariably correſpond with the ground that is occupied by the battalions and ſquadrons which conſtitute the *firſt* line; in order that the *firſt* line, on being forced to fall back, may find ſufficient ſpace to rally, and not endanger the diſpoſition of the *ſecond* line, by precipitately thronging and preſſing upon it. Each line is divided into right and left wings; each wing is compoſed of one or more diviſions: each diviſion is compoſed of one or more brigades; and each brigade is formed of two, three, or four battalions. Battalions are formed in line at a diſtance of twelve paces from each other, and this interval is occupied by two cannon, which are attached to each battalion. For the difference between the Pruſſian and French mode of arrangement, and other particulars, ſee ARMY, BATTLE, COLUMN, ENGAGEMENT, and TACTICS.

The LINE is a term frequently uſed to diſtinguiſh the regular army of Great Britain from other eſtabliſhments of a leſs military nature. All numbered, or marching regiments, are called *the line*. The guards are an exception to this rule. The marines, fencible, militia, volunteer, and yeomanry corps, together with the life-guards, are not comprehended under this denomination. The term line, however, has not been applied with ſufficient preciſion and diſcrimination. Strictly ſpeaking, line, in military matters, denotes that ſolid part of an army which is called the main body, and has a regular formation from right to left. Upon the whole, it may be obſerved, that the term is generally miſapplied, and that it cannot, with ſtrict propriety, be uſed to diſtinguiſh any particular eſtabliſhment from another.

LINE, *To*, from the French *aligner*, is to dreſs any given body of men, ſo that every individual part ſhall be ſo diſpoſed as to form collectively a ſtraight continuity of points from centre to flanks.

LINE *of March*, denotes the orderly ſucceſſion of the component parts of an army that is put in motion.

LINES *of March*, are bodies of armed men marching in given points to arrive at any ſtraight alignment on which they are to form. The line is ſaid to be well *dreſſed*, when no part is out of the ſtraight alignment. That this may be effected, at the word *dreſs*, which is given by the commander, it is immediately to commence from the centre of each battalion, the men looking to their own colours, and the correcting officers lining them upon the colours of their next adjoining battalion.

LINE-*firings* are executed ſeparately and independently by each battalion.

LINE *of Fire*. See FIRE.

LINE, *To form the*, is to arrange the troops in order of battle, or battle array.

LINE, *Inverſion of the*, is a manœuvre which is effected by facing a battalion or line to the right about, inſtead of changing its poſition by a countermarch; ſometimes it may be neceſſary to form to a flank with its rear in front. The column, with its line in front, may arrive on the left of its ground, and be obliged immediately to form up and ſupport that point, ſo that the right of the line will become the left. Part of a ſecond line may double round on the extremity of a firſt line, thereby to outflank an enemy. Theſe, and various other movements, may be found neceſſary, and they can only be practiſed with ſafety and expedition by the inverſion of the line.

LINES, *Retiring*, denote bodies of armed men that have advanced againſt an oppoſing enemy in order of battle, withdrawing themſelves with regularity from the immediate ſcene of action. On this occaſion, it is of the greateſt moment, that the line ſhould be correctly dreſſed before it faces to the right about; and the battalions will prepare for the retreat in the manner preſcribed for the ſingle one, by receiving the caution, that "the line will retire."

LINES *of Support*, are lines of attack, which are formed to ſupport one another. If there are ſeveral, the ſecond ſhould outflank the firſt, the third the ſecond, the advanced one being thereby ſtrengthened and ſupported on its outward wing.

To LINE *Men*. Officers and non-commiſſioned officers are ſaid to *line* the men belonging to their ſeveral battalions, diviſions, or companies when they arrive at their dreſſing points, and receive the word *dreſs* from the commander of the whole. When a ſingle battalion halts, it is dreſſed or lined on its right centre company, and muſt, of courſe, be in a ſtraight line. When ſeveral battalions dreſs from the centre of each on its next colour, the general line will be ſtraight, provided all the colours have halted regularly in a line. On theſe occaſions, every thing will depend upon the two centre dreſſes of each battalion.

To LINE *a Coaſt*, under the immediate preſſure of invaſion, requires not only great ability and exertion in the commanding officer of the particular diſtrict againſt which an inſult may be offered, but it is moreover neceſſary, that every individual officer in the different corps ſhould minutely attend to the particular ſpot on which he may be ſtationed. The Engliſh coaſt, eſpecially where there are bays, is almoſt always interſected by narrow paſſes through the rocks or ſand-hills. On this account, when any body of men receives orders to line a ſpecified extent of ground, the officers who are entruſted with the ſeveral parts of a battalion or brigade, ſhould take care to make the moſt of their men, and to extend their files in ſuch a manner, as not only to preſent an impoſing front from the crown of the hill, but to be able, at a moment's warning, to carry their whole ſtrength to prevent the enemy from getting upon the flanks by ſuddenly ruſhing up the gap. Much coolneſs is required on theſe occaſions.

To LINE *Hedges, &c.* to plant troops, artillery, or ſmall arms, along them under their cover, to fire upon an enemy that advances openly, or to defend them from the horſe, &c.

To LINE *a Street or Road*, is to draw up any number of men on each ſide of the ſtreet or road, and to face them inwards. This is frequently practiſed on days of ceremony, when ſome diſtinguiſhed perſon is received with military honours on his way through places where troops are ſtationed.

LINE, *To break the*, is to change the direction from that of a ſtraight line, in order to obtain a croſs-fire.

LINE, *Turning out of the*. The line turns out without arms whenever the general commanding in chief comes along the front of the camp. When the line turns out, the private men are drawn up in a line with the bells-of-arms; the corporals on the right and left of their reſpective companies; the picquet forms behind the colours, with their accoutrements on, but without arms. The ſerjeants draw up one pace in the front of the men, dividing themſelves equally. The officers draw up in ranks according to their commiſſions, in the front of the colours; two enſigns taking hold of the colours. The field-officers advance before the captains. The camp-colours on the flanks of the parade are to be ſtruck, and planted oppoſite to the bells-of-arms; the officers' ſpontoons are to be placed between the colours, and the drums piled up behind them; the halberts are to be planted between and on each ſide the bells-of-arms, and the hatchets turned from the colours.

LINE, or *Line of Battle*, in *Naval Tactics*, is applied to the diſpoſition of a fleet on the day of engagement; on which occaſion the veſſels are uſually drawn up as much as poſſible, in a ſtraight line, as well to gain and keep the advantage of the wind, as to run the ſame board. See ENGAGEMENT.

This right line, or long file, is prolonged from the keel of the hindmoſt to that of the foremoſt, and paſſes longitudinally through the keels of all the others, from the van to the rear; ſo that they are, according to the ſea-phraſe, in the wake of each other. In the line, or order of battle, all the ſhips of which it is compoſed are cloſe hauled, upon the ſtarboard or larboard tack, about fifty fathoms diſtant from each other. When a fleet is drawn up in line, in preſence of an enemy, it ſhould be formed in ſuch a manner as that the ſhips may mutually ſuſtain and reinforce each other, and yet preſerve a ſufficient ſpace in their ſtations, to work or direct their movements with facility during the action. The line cloſe-hauled is peculiarly choſen as the order of battle, becauſe, if the fleet, which is to windward, were arranged in any other line, the enemy might ſoon gain the weather-gage of it; and even if he thinks it expedient to decline that advantage, it will yet be in his power to determine the diſtance between the adverſe fleets in an engagement, and to compel the other to action. The fleet to leeward, being in a line cloſe-hauled, parallel to the enemy, can more readily avail itſelf of a change of the wind, or of the neglect of its adverſary, ſo as to get to windward of him; or, at leaſt, ſo as to avoid coming to action, if the enemy is much ſuperior, or to prevent him from eſcaping, if he ſhould attempt it. Beſides, in this order, the ſails of yarn. (9 Geo. II. c. 4.) By 14 Geo. III. c. 72. it is enacted that no greater duty ſhall be paid for ſtuffs made of raw cotton wool within this kingdom than 3½*d*. a yard, 43 Geo. III. c. 69. and that any perſon may uſe the ſame in apparel or otherwiſe: and every piece is to have three blue ſtripes in both ſelvedges, and to be ſtamped at each end with a ſtamp provided by the officers of exciſe, and inſtead of the word *calico*, uſed for foreign calicoes, each piece ſhall be marked with the words *Britiſh Manufactory*. If ſtuffs made wholly of cotton, and printed, painted, ſtained, or dyed ſtuffs, (muſlins, neckcloths, and fuſtians excepted,) without ſuch mark ſhall be expoſed to ſale, they ſhall be forfeited, and 50*l*. for each piece. If any perſon ſhall counterfeit ſuch ſtamp, or knowingly ſell ſuch ſtuffs with a counterfeit ſtamp, he ſhall be guilty of felony without benefit of clergy. If any perſon ſhall import any calicoes, muſlins, or other ſtuffs made of linen yarn only, or of linen yarn and cotton wool mixed, or wholly of cotton wool, in which ſhall be wove in the ſelvedge any ſuch blue ſtripe, he ſhall forfeit the ſame, and 10*l*. for each piece. Every ſuch printer, painter, ſtainer, or dyer, ſhall give notice in writing, at the next office, of his name and place of abode, and where he intends to work, on pain of 50*l*. (10 Anne, c. 19. 25 Geo. III. c. 72.) By 1 Geo. ſt. 2. c. 34. any perſon, undertaking to print, paint, &c. any ſilks, linens, or ſtuffs, at any other place than the place of his uſual reſidence or exerciſe of his trade, ſhall firſt make entry of the place, and pay the duties, on pain of 50*l*., and forfeiture of the goods. Officers may enter at all times by day or night to take account, &c. and the penalty of obſtructing the officer in the execution of his duty is 200*l*. (10 Anne, c. 19. 25 Geo. III. c. 72.) Goods ſhall be entered once in ſix weeks on oath before the collector or ſuperviſor, on pain of 50*l*. (10 Anne, c. 19.) No perſon ſhall begin to print, ſtain, paint, or dye any goods before they have been meaſured and marked, on pain of forfeiting the ſame, and alſo 20*l*. for every piece. (25 Geo. III. c. 72.) If any printer ſhall wilfully cut out or deface ſuch frame mark, he ſhall forfeit 50*l*. Concealing goods, or avoiding duty, incurs a forfeiture of 50*l*.: and all goods found in a place, of which no notice has been given, or the value thereof, ſhall be forfeited. (10 Anne, c. 19. 25 Geo. III. c. 72.) Nor ſhall goods be kept in unentered places on pain of forfeiting 50*l*. and the goods. 20 Geo. III. c. 72.) Within ſix weeks the duties ſhall be cleared, on pain of forfeiting double. (10 Anne, c. 19.) Nor ſhall they be removed before the officer hath taken account of them and ſtamped them, on pain of 50*l*. and ſeizure. (10 Anne, c. 19. 25 Geo. III. c. 72.) Goods ſurveyed ſhall be kept ſeparate from thoſe unſurveyed, on pain of 50*l*.: and goods unſtamped may be ſearched for and ſeized. (10 Anne, c. 19. 25 Geo. III. c. 72.) The perſon in whoſe cuſtody ſuch goods are found ſhall forfeit 100*l*. 5 Geo. c. 11. 27 Geo. III. c. 31.

Calicoes, &c. that ſhall not have three blue threads in the ſelvedge, ſhall be deemed foreign calicoes, and on being printed or dyed, ſhall be marked at each end with the words "foreign calicoes for exportation;" and every dealer who ſhall have any ſuch goods in his cuſtody (except dyed throughout of one colour) or any ſtuffs made wholly of cotton wool wove in Great Britain, commonly called "Britiſh Manufactory," (muſlins, neckcloths, and fuſtians excepted,) not having ſuch blue threads, ſhall forfeit 200*l*. and every ſuch piece found in his cuſtody. (25 Geo. III. c. 72.) The owner or printer of any piece or remnant of coſſac or foreign muſlins and calicoes ſhall, before they be preſented to the officer, mark the ſame at both ends with a frame mark, containing his name and place of abode, and alſo the name by which ſuch goods are commonly known (except ſuch as are dyed throughout of one colour) on pain of forfeiting 10*l*. for every piece or remnant. The owner or printer of any linens or ſtuffs made of cotton mixed, or wholly of cotton wool wove in Great Britain, called "Britiſh Manufactory or Muſlins," ſhall mark the ſame at both ends (fuſtians, velvets, velverets, dimities, and other figured ſtuffs excepted) with a mark, containing his name and place of abode, and the name and quality of ſuch goods, with the ready money price thereof, before the ſame are preſented to the officer in order to be printed or dyed; on pain of forfeiture and ſeizure, and 20*l*.; and if any ſuch piece be marked at a leſs price than the real value, the ſame may be ſeized and forfeited, and the owner ſhall forfeit 20*l*. If the frame mark be defaced, the ſame ſhall be renewed on notice; but if any perſon ſhall counterfeit or forge any frame mark, he ſhall forfeit 100*l*.: and if any perſon counterfeit the ſtamp, it is felony without benefit of clergy. (25 Geo. III. c. 72. 27 Geo. III. c. 31.) If any perſon ſhall knowingly ſell any of the goods with a counterfeit ſtamp, he ſhall forfeit 100*l*. and ſtand two hours in the pillory. (10 Anne, c. 19. 13 Geo. III. c. 56. 25 Geo. III. c. 72.) By 27 Geo. III. c. 31. if any perſon ſhall knowingly ſell any ſuch goods with counterfeit ſtamp, thus intending to defraud his majeſty, he ſhall be guilty of felony without benefit of clergy. Every perſon who hath paid the duties, or bought the goods of any perſon who hath paid the duties, may export the ſame, and ſhall be allowed all the duties in drawback, as ſet forth in 43 Geo. III. c. 69. Sched. C. on conforming to certain preſcribed conditions. (25 Geo. III. c. 72. 25 Geo. III. c. 74.) By the 4 Geo. III. c. 37. which eſtabliſhes the corporation of the Engliſh Linen Company for making cambrics and lawns, it is enacted that the commiſſioners of exciſe, where there ſhall be a manufactory of cambrics or lawns, or of goods known under that denomination, ſhall appoint the ſuperviſor or other officer to ſeal the ſame, for which they ſhall have ſuch fee as the commiſſioners ſhall appoint: the manufacturer to give notice in writing to the officer, of the finiſhing of every piece, before it is taken out of the loom, who ſhall ſeal the ſame at both ends; on pain that ſuch manufacturer, taking the ſame out of the loom without having given ſuch notice, and having the ſame ſealed as aforeſaid, ſhall forfeit 5*l*.; and every ſuch piece ſhall be forfeited, and may be ſeized by any officer of the cuſtoms or exciſe, and the officer, with convenient ſpeed after notice, ſhall mark and alſo number each piece; and make entry in writing, in books to be provided at the expence of the manufacturer, of the number ſet to each piece, the length thereof, and the number of threads in the warp, on pain of 10*l*. If the officer ſhall mark any not made in England, or after the ſame is taken out of the looms, he ſhall forfeit 50*l*. for each piece to him who ſhall ſue, and forfeit his office, and be incapacitated to hold any other office of truſt under the crown. If any perſon ſhall offer to the officer any bribe, he ſhall forfeit 50*l*.; and if he ſhall by bribery, or otherwiſe, prevail upon the officer to commit ſuch offence, he ſhall forfeit 100*l*., and ſtand in the pillory two hours. And the officer ſhall yearly, in the month of June, tranſmit to the commiſſioners an account of all goods which he ſhall have ſtamped, and a copy of the entries made, on pain of diſmiſſion; and he, or his executors, ſhall deliver up the ſeals, on demand from the commiſſioners, on pain of 200*l*. Cambrics and lawns made in England found unſtamped, ſhall be forfeited, and may be ſeized by any officer of the cuſtoms or exciſe, and after condemnation ſhall be ſold; and every perſon who ſhall ſell or expoſe to ſale, or have in his cuſtody

For that purpoſe, any cambrics or lawns made in England, unmarked, ſhall forfeit 200*l.* ſuch goods not to be ſold, or worn in this kingdom, but to be exported, and to be ſold only on condition of exportation. Nor ſhall they be delivered out of the warehouſe until bond be given, to the ſatisfaction of the collector, in double penalty of the goods, that the ſame ſhall be exported, and not relanded. To counterfeit the ſeal appointed by this act, or import any foreign cambrics or lawns having ſuch counterfeit mark thereon, or expoſe the ſame to ſale, knowing the ſtamp thereon to be counterfeited, is felony without benefit of clergy. All goods condemned in purſuance of this act, and all pecuniary forfeitures (not otherwiſe directed) ſhall be ſued for and recovered in any of his majeſty's courts, in the name of the attorney-general, or of ſuch officer as aforeſaid; and applied, after deduction of charges, half to the king, and half to the officer ſeizing, informing, or ſuing, according to the directions of this act. The penalties may be ſued for, levied, and mitigated as by the laws of exciſe, or in the courts at Weſtminſter; and employed half to the king, and half to him that ſhall diſcover, inform, or ſue. (10 Anne, c. 19. 34 Geo. II. c. 40. 25 Geo. III. c. 72.) All utenſils and inſtruments for printing, painting, ſtaining, or dyeing ſuch goods, in cuſtody of the ſaid perſon, or any other, ſhall be liable to all arrears of the duty, and to all penalties concerning the ſame, in like manner as if ſuch perſon was the lawful owner. 10 Anne, c. 19. 25 Geo. III. c. 72. 28 Geo. III. c. 37.

Stealing of linen, fuſtian, cotton goods, &c. from whitening-grounds or drying houſes, to the value of 10*s.* or knowingly buying or receiving ſuch ſtolen goods, is felony without benefit of clergy. (18 Geo. II. cap. 27.) Such alſo is breaking into houſes, ſhops, &c. and deſtroying any linen cloth, or implements uſed in the manufacturing of it, by 4 Geo. III. cap. 37. See LARCENY.

A new manufacture was ſet on foot ſome time ago in London, for embelliſhing linen with flowers and other ornaments of gold leaf. The linen looks whiter than moſt of the printed linens; the gold is extremely beautiful, and is ſaid to bear waſhing well. See STUFF.

There are many ſubſtances from which a juice or dye is obtained, that will ſtain linen of different colours. The juice of the anacardium, rubbed on linen or cotton, gives a reddiſh-brown ſtain, which ſoon deepens in the air into a black, and which has not been diſcharged by waſhing and boiling, with ſoap or alkaline ley. Hence the anacardium is ſaid to be uſed for marking linen and cotton cloths, and to be known all over India by the name of marking-nut. The juice of the caſhew-nut, called by ſome the anacardium of the Weſt Indies, differs from the oriental anacardium in its colouring quality; that lodged between its ſhells being much paler, and giving to linen, cotton, or paper, only a browniſh ſtain, which is durable, but does not change at all towards blackneſs.

Several ſpecies of the toxicodendron, or poiſon-wood, contain in their leaves a milky juice, which in drying becomes of a deep black, and communicates the ſame colour to the linen on which it is dropped: the linen thus ſtained, boiled with ſoap, came out without the leaſt diminution of its colour, nor does ſtrong ley of wood-aſhes make any change in it. Phil. Tranſ. vol. xlix. for 1755.

Dr. Lewis has found, that the milks of wild poppies, garden poppies, dandelion, hawk-weed, and ſow-thiſtle, gave brown or browniſh-red ſtains, which were diſcharged by waſhing with ſoap; the colourleſs juice which iſſues from hop-ſtalks when cut, ſtains linen of a pale reddiſh or browniſh-red, extremely durable: the juice of ſloes gave likewiſe a pale browniſh ſtain, which, by repeated waſhings with ſoap, and wetting with ſtrong ſolution of alkaline ſalt, was darkened to a deeper brown; on baking the ſloes, their juice turns red, and the red ſtain which it then imparts to linen is, on waſhing with ſoap, changed to a pale blueiſh, which alſo proves durable. See DYEING *of Thread.*

The late Dr. Smellie has recommended the following method of marking linen, ſo as not to waſh out again: take vermilion, as much as will lie on a half-crown piece, of the ſalt of ſteel a piece about the ſize of a ſmall nutmeg; grind or levigate them well together with linſeed oil: the compoſition may be diluted or thickened at pleaſure.

LINEN, *Foſſil.* See AMIANTHUS and ASBESTOS.

LINEN *Mills.* See MILL.

LINEN, *White.* See WHITE.

LINEN, *Bleaching of.* See BLEACHING.

LIN-FOU, in *Geography*, a town of Corea; 20 miles S. of Haimen.

LING, in *Agriculture*, a provincial term applied to the plant uſually known by the name of heath. See HEATH.

By 4 & 5 W. c. 23. no perſon ſhall on any mountains, hills, heaths, moors, foreſts or chaſes, or other waſtes, burn between February 2, and June 24, any grig, ling, heath, furze, goſs or fern, on pain of being committed to the houſe of correction, for any time not exceeding one month, nor leſs than 10 days, then to be whipped and kept to hard labour.

LING, in *Ichthyology*, the Engliſh name for a kind of fiſh, which is a ſpecies of the gadus, with two fins on the back, with a bearded mouth, and with the upper jaw longeſt. See GADUS *Molva.*

Ling is eſteemed, both freſh and cured, for the table.

This fiſh abounds about the Scilly iſles, on the coaſts of Scarborough, and thoſe of Scotland and Ireland, and forms a conſiderable article of commerce. In the Yorkſhire ſeas they are in perfection from the beginning of February to the beginning of May, and ſome till the end of that month. They ſpawn in June, at which time the males ſeparate from the females. When the ling is in ſeaſon, its liver is very white, and abounds with a fine flavoured oil, which afterwards becomes red, like that of a bullock, and affords no oil. This oil is ſaid to be hoarded up in the cellular membranes of fiſhes, to return into their blood, and ſupport them in the engendering ſeaſon. Great quantities of this fiſh are ſalted for exportation, and for home-conſumption: for this purpoſe it muſt meaſure twenty-ſix inches or upwards from the ſhoulder to the tail, in order to be entitled to the bounty on exportation. Thoſe under that ſize are called *drizzles.* Pennant.

LINGA, in *Geography*, one of the ſmaller Shetland iſlands, near the N. coaſt of Mainland. N. lat. 60° 44′. W. long. 1° 27′.—Alſo, one of the ſame group of iſlands near the E. coaſt of Mainland. N. lat. 60° 34′. W. long. 1° 6′.—Alſo, one of the ſame cluſter, near the S.W. coaſt of Uiſt. N. lat. 61° 2′. W. long. 1° 12′.—Alſo, one of the ſmall weſtern iſlands of Scotland, near the S. coaſt of South Uiſt. N. lat. 57° 3′. W. long. 7° 19′.

LINGA *Sound*, a bay on the W. coaſt of the iſland of Stronſa. N. lat. 59°. E. long. 0° 28′.

LINGA, or *Lingam*, as it is pronounced in the ſouthern and eaſtern parts of the peninſula, in *Hindoo Mythology*, is a ſymbol to which great veneration is paid, and much myſticiſm attached, by the extenſive ſect of Hindoos called Saivas, or the worſhippers of Siva, the deſtructive, or rather regenerative power of their triad. This type of Siva is repreſented of a conical form, and is ſeen in almoſt all parts of India, of various ſizes, in ſtone, wood, clay, metals, &c.

It may be ſuppoſed that Siva, being, among his other attributes, a perſonification of fire, as the moſt deſtructive of elements, was typified by a cone with its apex upwards, the form naturally aſſumed by flame; and that to this form enthuſiaſts have, in the wildneſs of their imagination, fancied alluſions, and directed analogies, that, in the progreſs of time, have more and more bewildered them; until at length ſuch an inextricable maſs of myſticiſm hath been accumulated referring to this ſymbol, as to wear an appearance almoſt of ridicule. The Linga being the ſymbol of Siva, his votaries are reminded of it, and of its archetype by any thing conical or erect; a hill, a tree, any pyramidal object, a maſt or pole, &c. Lingas are ſeen of enormous ſize; in the cavern of Elephanta for inſtance, marking unequivocally that the ſymbol in queſtion is at any rate as ancient as that temple, as they are of the ſame rock as the temple itſelf; both, as well as the floor, roof, pillars, pilaſtres, and its numerous ſculptured figures, having been once one undiſtinguiſhed maſs of granite, which excavated, chiſſelled, and poliſhed, produced the fire cavern, and forms that are ſtill contemplated with ſo much ſurprize and admiration. The magnitude of the cones, too, farther preclude the idea of ſubſequent introduction, and together with gigantic ſtatues of Siva and his conſort, more frequent and more coloſſal than thoſe of any other deity, neceſſarily, as before noticed, coeval with the excavation, indicate his paramount adoration, and the antiquity of his ſect. (See ELEPHANTA and KARLY.) Lingas are ſeen alſo of diminutive ſize for domeſtic adoration, or for perſonal uſe; ſome individuals always carrying one about with them, and in ſome Brahman families one is daily conſtructed in clay, placed, after due ſanctification by appropriate ceremonies and prayers, in the domeſtic ſhrine, or under a tree or ſhrub ſacred to Siva, the Bilva (Cratæva marmelos) more eſpecially, and honoured by the adoration of the females of the houſhold. This ceremony is called Linga-puja, *i. e.* the worſhip of the Linga, a beautiful plate of which, with a particular deſcription, is given in Moor's Hindu Pantheon, where "a pious female is repreſented in plate 22, propitiating Mahadeva (another name of Siva) in his generative character, indicated by the Linga, inſerted in its appropriate receptacle the Argha, or Yoni, myſterious types of nature, particularly diſcuſſed in future pages. The devout female may be imagined as invoking the deities, typified by their ſymbols, for the bleſſing of fruitfulneſs, its reverſe being deprecated by both ſexes, as the moſt afflicting viſitation of divine diſpleaſure. It is explained hereafter, how certain ceremonies called Sradha, to be performed by the offspring of defunct parents, are eſſential to the repoſe of a departed ſoul." P. 68. See SRADHA, YONI, and MERU.

A ſect of Hindoos worſhip almoſt excluſively the Linga, as the ſymbol of their deity: this ſect is called *Lingaja*, *Lingancita*, and *Lingi*. Another ſect, excluſive worſhippers of the *Yoni*, or the female power, are called Yonija; the former being apparently the ſame as the Phallic emblem of the Greeks, the *membrum virile*; and the latter *pudendum muliebre*, rarely, however, ſeen in India in an indecent form. "The myſtery in which the real hiſtory of theſe emblems is veiled, renders it extremely difficult to give a clear account of the origin or tendency of the rites by which we ſee their votaries honour them. That they had their origin in nature and innocence we may admit, without admitting likewiſe the propriety of their continuance to a period when nature and innocence are no longer ſeen unſophiſticated: knowing, however, ſo little of the genuine hiſtory of theſe rites and ſymbols, it is but a reaſonable extenſion of charity to ſuppoſe that their origin was philoſophical though myſterious, and that their obſervance, though offenſive to delicacy, is not criminal.

"It is ſome comparative and negative praiſe to the Hindoos, that the emblems under which they exhibit the elements and operations of nature, are not externally indecorous. Unlike the abominable realities of Egypt and Greece, we ſee the Phallic emblem in the Hindoo exhibitions without offence; and know not, until the information be extorted, that we are contemplating a ſymbol, whoſe prototype is obſcene. The plates of this work may be turned and examined over and over, and the uninformed obſerver will not be aware that in ſeveral of them he has viewed the typical repreſentation of the generative organs or powers of humanity. The external decency of the ſymbols, and the difficulty with which their recondite alluſions are diſcovered, both offer evidence favourable to the moral delicacy of the Hindoo character. I am not, however, prepared to deny the appearance, in many inſtances, of ſtrong evidence to the contrary; the diſguſting faithfulneſs of natural delineations, and the combinations ſo degrading to human nature, obſervable on ſome of the temples and ſacred equipages of the Hindoos, are deeply offenſive to common delicacy and decency; and I continue of opinion that ſuch objects of depravity, publicly offered to juvenile contemplation, cannot fail of exciting in ſuch untutored, eſpecially female, minds, ideas obnoxious to the innocence that we love to think an inmate there." (Hin. Pan. p. 382.) Something on this topic, and an inſtance of the adoration of the Linga in a magnificent temple, occur under the articles IDOLATRY and JEJURY. See alſo PHALLUS. The ſimilarity of Phallic and of Linga worſhip, and other Grecian, Egyptian, and Hindoo coincidences, are learnedly diſcuſſed by major Wilford in the third, fourth, ſixth, and eighth volumes of the Aſiatic Reſearches. See GENTOOS and LOTOS, in this work.

LINGAJA, a ſect of Hindoos, who adore, it is ſaid, excluſively, the Linga, a ſymbol of Siva. See LINGA, and SECTS *of Hindoos*.

LINGAN, in *Geography*, a river of Ireland, which runs into the Suir; 2 miles below Carrick-upon-Suir.

LINGANCITA, a ſect of Hindoos, the ſame with Lingaja, who excluſively worſhip Siva under the ſymbol of a Linga or Phallus. See LINGA, and SECTS *of Hindoos*.

LINGAPOUR, in *Geography*, a town of Hindooſtan, in Dowlatabad; 15 miles S. of Neermul.

LINGAY, one of the ſmaller weſtern iſlands of Scotland, near the S.W. coaſt of Harris. N. lat. 57° 40'. W. long. 7°.

LING-CHAN, a town of Corea; 76 miles E.N.E. of Han-tcheou.

LINGEN, a city of Weſtphalia, and capital of a county of the ſame name; formerly fortified, but now barely ſurrounded with a ditch, and ſmall. It is the ſeat of the regency of the united counties of Lingen and Tecklenburg, and of the deputations of the war and domain chamber of Minden, and has a Calviniſt, a Lutheran, and a Roman Catholic church. The academical gymnaſium of this place was founded in 1697 by William III., prince of Orange. About a quarter of a mile diſtance from the town, N. of it, is the paſſage over the Embs, called the "Lingen Ferry."—Alſo, a county of Weſtphalia, bounded on the N. by the biſhopric of Munſter, on the E. by the biſhopric of Oſnabruck, on the S. by the county of Tecklenburg, and on the W. by Bentheim. At the peace of Tilſit it was ceded by Pruſſia to Weſtphalia. It has mines of coal and quarries of ſtone. The chief town of the upper diviſion of the county is Lingen, and that of the lower Ibbenbuhren.—Alſo, an iſland in the Eaſt Indian ſea, near the S. coaſt of Malacca, about 100 miles in circumference, and 50 miles from the N.E. coaſt of the iſland of Sumatra. S. lat. 0° 10′. E. long. 104° 40′.

LINGENDES, Claude de, in *Biography*, a French Jeſuit, and one of the moſt celebrated preachers of the period in which he flouriſhed, was born at Moulins in the year 1591. He entered the order when he was ſixteen years of age, and after completing his ſtudies to the ſatisfaction of his ſuperiors, became eminent as an inſtructor in rhetoric and polite literature. His chief talent was ſoon diſcovered by the eloquence of his pulpit diſcourſes, and for ſix and thirty years he attracted crowded audiences by the excellence of his compoſitions, and by his fine elocution. Beſides the labours of the pulpit, he preſided eleven years over the college of his native place, and afterwards filled the poſt of provincial of the order in France. He died in 1660, at the age of ſixty-nine, while he was ſuperior of the Jeſuits' ſeminary at Paris. He was author of a popular work, entitled "Monita quædam ad Vitam bene Ordinandam," which has been frequently reprinted: "Votivum Monumentum ab Urbe Molinenſi, Delphino oblatum;" and of Latin ſermons, entitled "Concionum quadrageſimalium Argumenta," which have been publiſhed in 4to. and 8vo. and which have been tranſlated into the French language, and much read in the original and tranſlation. Gen. Biog.

LINGHOLM, in *Geography*, a ſmall iſland among the Orkneys, near the W. coaſt of Stronſa. N. lat. 50° 59′. E. long. 0° 27′.

LINGI, a ſect of Hindoos, worſhippers of the Linga, a Phallic emblem of Siva, the deſtructive and regenerative power of the Indian triad. See Linga, Sects *of Hindoos*, and Siva.

LINGICOTTA, in *Geography*, a town of Africa, in Kullo. N. lat. 12° 30′. W. long. 9° 10′.

LINGLEBACH, John, in *Biography*, a painter of groteſque ſubjects, fairs, mountebanks, landſcapes, &c.; born at Frankfort on the Maine in 1625; who having early acquired ſome knowledge of the art of painting, went to Rome for his improvement, but returned to his native country at the age of 25, to practiſe in his own native ſtyle. He did indeed acquire in Italy a ſlight taſte for the claſſic, which he exhibited by introducing ſplendid ruins ſometimes in his landſcapes; but in general his taſte is Dutch, and his ſtyle alſo, particularly in colouring and effect. His pictures are in general pleaſing, having very much the tone of thoſe of Adrian Vandevelt, though not finiſhed ſo minutely, and indeed differing in choice of ſubject. He was frequently employed by eminent artiſts to inſert figures and animals in their landſcapes; and his ingenuity in the management of his pencil, enabled him ſo to aſſimilate his touch to that of the painter who employed him, that it is not eaſy to diſcover his hand. He died in 1687, at the age of 62.

LING-NGAN, in *Geography*, a city of China, of the firſt rank, in Yun-nan. N. lat. 23° 38′. E. long. 102° 42′.

LINGNIANY, a town of Lithuania; 32 miles E. of Wilkomerz.

LINGONES, in *Ancient Geography*, a people of Gallia Ciſalpina, near the Po, and north of the Boii, in the northern part of Bologneſe and in Ferrara. They formed leagues of amity with the Boii, and, like them, they were Gauls in their origin; and their deſcent has been traced by ſome authors from the Lingones of Gallia Tranſalpina, where they inhabited a territory near the preſent Langres. Their towns in Italy were Forum Cornelii, Claterna, Faventia, Solonæ, and Butrium. Traces of the ſame people have been alſo diſcovered in Upper Germany.

LING-QUAN-Y, in *Geography*, a town of China, in the province of Chen-ſi; 50 miles S.W. of Si-ngan.

LING-TAO, a town of China, of the firſt rank, in Chen-ſi, ſituated on the Tie-tſan river, which falls into the Hoang-ho, or Yellow river. Gold is found in great quantities in the ſand of the neighbouring rivers and brooks. The country is very mountainous, and abounds with wild bulls, and an animal reſembling a tyger, whoſe ſkins are very valuable. The vallies are fertile in corn, and the paſtures near the rivers ſupply food for cattle. Upon this city depend two cities of the ſecond claſs, and three of the third. N. lat. 25° 22′. E. long. 106° 34′.

LING-TCHEOU, a town of Corea; 28 miles S.S.W. of Koang-tcheou.

LINGUA Groſſa, a town of Sicily, in the valley of Demona; 9 miles W. of Taormina.

Lingua, *Tongue*, in *Anatomy*. See Deglutition and Tongue.

Lingua *Avis*, *Bird's-tongue*, in the *Materia Medica*, the ſeed of the aſh-tree, or aſhen-keys.

Lingua *Cervina*, in *Botany*, Hart's Tongue, a ſpecies, or with Plumier, Tournefort, and others, a genus of the fern tribe. See Asplenium and Scolopendrium.

Lingua *Medietas*, in *Law*. See Medietas.

LINGUÆ Frænum, in *Anatomy* and *Surgery*. See Frænum.

LINGUADO, in *Ichthyology*, the name of a Weſt Indian fiſh, in ſhape reſembling a ſoal.

LINGUALIS, in *Anatomy*, an epithet applied to ſome parts about the tongue. The lingual artery is a large branch of the external carotid. (See Artery.) For the lingual glands, ſee Deglutition; for the lingualis muſcle, ſee Deglutition; and for the lingual nerve, ſee Nerve.

LINGUATULA, in *Ichthyology*, a ſpecies of *pleuronectes*; which ſee.

Linguatula, in *Natural Hiſtory*, a genus of the vermes molluſca claſs and order: body depreſſed, oblong; mouth placed before, ſurrounded with four paſſages. Of this genus there is but a ſingle ſpecies; *viz.* the *Serrata*, which inhabits the lungs of a hare.

LINGULA, in *Ichthyology*, the name of an extremely ſmall fiſh of the ſoal-kind. It is known from the reſt of this genus not only by its ſmallneſs, but by a ridge of ſmall ſcales, which run along the line over the ſpine, and are much more elevated and diſtinguiſhable, both to the eye and touch, than thoſe of the reſt of the body. It is a well-taſted fiſh, and much firmer in its fleſh than the ſoal, but is very ſcarce, and is of little value, becauſe of its thinneſs. It is caught in the Mediterranean.

LINGULACA, a name by which ſeveral authors, particularly ſome of the older naturaliſts, have called the *ſoal fiſh*.

LINGULATUM Folium, in *Botany*. See Leaf.

LINGUMPILLY, in *Geography*, a town of Hindooſtan, in Myſore; 30 miles S.W. of Tademeri.

LINHARES, a town of Portugal, in the province of Tras los Montes; 19 miles S. of Mirandela.—Alſo, a town of Portugal, in the province of Beira; 5 miles S.W. of Calorico.

LINHAY, in *Rural Economy*, a provincial word applied in Devonſhire to ſignify an open ſhed.

LINIE'RES, La, in *Geography*, a town of France, in the department of the Charente; 15 miles S.W. of Angouleſme.

LINIMENT, Linimentum, from the Latin *linire*, *to anoint gently*, in *Pharmacy*, a form of external medicine, made of unctuous ſubſtances, uſed to rub on any diſtempered part.

The liniment is of a mean conſiſtence between an oil and an unguent.

The uſe of liniments is to ſoften aſperities of the ſkin, moiſten parts that need humectation, and reſolve the humours that afflict the patient and give him pain. There are various kinds of liniments uſed, according to the various occaſions.

LINIMENTUM Album, P. L. 1745; *Unguentum ſpermaceti*, P. L. 1787; *Unguentum cetacei*, P. L. 1809, ointment of ſpermaceti, is formed as follows: take oil-olive three ounces, ſpermaceti ſix drachms, white wax two drachms; melt all together over a gentle fire, ſtirring it till it is perfectly cold.

This liniment may be applied in caſes of excoriation, where, on account of the largeneſs of the ſurface, the ointment with lead or calamine might be improper.

Linimentum *Æruginis*, *Liniment of Verdigris*, P. L. 1809; *Unguentum Ægyptiacum*, P. L. 1720; *Mel Ægyptiacum*, P. L. 1745; *Oxymel æruginis*, P. L. 1787, is prepared by diſſolving an ounce of powdered verdigris in ſeven fluid-ounces of vinegar, and ſtraining it through a linen cloth; then adding gradually fourteen ounces of clarified honey, boil it down to a proper conſiſtence. This preparation is intended only for external uſe.

Linimentum *Ammoniæ Fortius*, *ſtrong liniment of ammonia*, is formed by ſhaking together a fluid-ounce of ſolution of ammonia, with two fluid-ounces of olive oil, until they unite.

Linimentum *Ammoniæ Carbonatis.* See **Linimentum** *Volatile*.

Linimentum *Arcæi*, P. L. 1720; *Unguentum e gummi elemi*, P. L. 1745; *Unguentum elemi compoſitum*, P. L. 1787, is a compoſition formed by melting a pound of elemi with two pounds of prepared ſuet; then removing it from the fire, and immediately mixing in ten ounces of common turpentine, and two fluid-ounces of olive oil; then ſtraining the mixture through a linen cloth. See Elemi.

Linimentum *Camphoræ*, *Camphor liniment*, is prepared by diſſolving half an ounce of camphor in two fluid-ounces of olive oil. This is a ſimple ſolution of camphor in oil, which readily diſſolves it. The ſame ſolution alſo affords an uſeful method of giving camphor internally in a liquid form, by rubbing it in this ſtate firſt with mucilage, and then adding any aqueous vehicle. One drachm of the oil contains, as thus prepared, fifteen grains of camphor. See Camphor.

Linimentum *Camphoræ Compoſitum*, *Compound camphor liniment*, is prepared by mixing ſix fluid-ounces of ſolution of ammonia with a pint of ſpirit of lavender in a glaſs retort; then, by the heat of a ſlow fire, diſtilling a pint; and laſtly in this diſtilled liquor diſſolving two ounces of camphor. See Camphor.

Linimentum *Hydrargyri*, *Mercurial liniment*, conſiſts of the following ingredients; *viz.* ſtrong mercurial ointment and prepared lard, of each four ounces, an ounce of camphor, 15 minims (of which 60 make a fluidrachm) of rectified ſpirit, and four fluid-ounces of ſolution of ammonia. It is prepared by firſt powdering the camphor with the addition of the ſpirit, then rubbing it with the mercurial ointment and the lard, and, laſtly, adding gradually the ſolution of ammonia, and mixing the whole together. This combination requires that the camphor ſhould be powdered by the ſmalleſt poſſible quantity of ſpirit, and if the other ſubſtances be added in the manner above directed, it will form a maſs of uniform conſiſtence without ſeparating; and it will be conſiderably thicker than the other liniments are. It is an uſeful combination for the diſcuſſion of indolent ſwellings or collections of fluid; but if it be frequently or largely applied, it will affect the mouth more rapidly than the mercurial ointment will do.

Linimentum *Saponaceum*, *Linimentum ſaponis compoſitum*, or *compound ſoap-liniment*, a form of medicine preſcribed in the London Pharmacopeia, and meant to ſupply the place of the ointment well known by the name of *opodeldoc*. It is made thus: take ſpirit of roſemary a pint, hard Spaniſh ſoap three ounces, camphor one ounce; diſſolve the camphor with the roſemary ſpirit, and then add the ſoap; and macerate in the heat of a ſand-bath until it be melted.

A liniment of this kind may be prepared by rubbing an ounce of camphor, with two ounces of Florence oil, in a mortar, till the camphor be diſſolved. This anti-ſpaſmodic liniment may be uſed in obſtinate rheumatiſms, and in ſome other caſes, accompanied with extreme pain and tenſion of the parts.

Linimentum *Terebinthinæ*, *Turpentine liniment*, is formed by adding half a pint of oil of turpentine to a pound of reſin cerate previouſly melted, and mixing. This liniment is very commonly applied to burns; and its firſt introduction into practice for this purpoſe is owing to Mr. Kentiſh of Newcaſtle.

Linimentum *Volatile*, P. L. 1745; *Linimentum ammoniæ*, P. L. 1787; *Linimentum ammoniæ carbonatis*, *liniment of carbonate of ammonia*, is formed by ſhaking together a fluid-ounce of ſolution of carbonate of ammonia with three fluid-ounces of olive-oil, until they unite. Or this liniment may be prepared by ſhaking together an ounce of Florence oil, and half an ounce of ſpirit of hartſhorn. If the patient's ſkin is able to bear it, the liniment, made with equal parts of the ſpirit and oil, will be more efficacious. Sir John Pringle obſerves, that in the inflammatory quinſey, a piece of flannel moiſtened with the liniment and applied to the throat, to be renewed every four or five hours, is one of the moſt efficacious remedies; and that it ſeldom fails, after bleeding, either to leſſen or carry off the complaint.

A liniment for burns may be made by ſhaking well together, in a wide-mouthed bottle, equal parts of Florence oil, or of freſh drawn linſeed oil, and lime-water. This is found to be an exceeding proper application for recent ſcalds or burns. It may either be ſpread upon a cloth, or the parts affected may be anointed with it twice or thrice a day.

A liniment for the piles may be made by mixing two ounces of emollient ointment, and half an ounce of liquid laudanum, with the yolk of an egg, and working them well together.

LINING, in *Canal-Making*, ſignifies a thickneſs or coat of puddle, ſometimes applied to the bottoms and ſides of canals, to prevent them from leaking, as *q r s t*, *Plate* I. *Canals*, *fig.* 15.

Lining *of Hot-beds*, in *Gardening*, is the art or practice of applying a proper layer of hot dung to the ſides of the beds, to revive and keep up the declining heat of them. It is eſſentially neceſſary, in the culture of plants on dung hot-beds, in the early ſeaſons in winter or ſpring, until May. As theſe hot-beds generally, in from three or four to five or ſix weeks, according to their ſubſtance, begin to decline in their degree of heat, they require of courſe a revival to continue them in regular heat; which, in dung hot-beds, can only be effected in this manner. It is applied to one or both ſides, as there may be occaſion, or as heat may be wanted.

Hence in this way, by the occaſional repetition of two, three, or more linings, a hot-bed may be continued in a proper degree of heat ſeveral months, as exemplified in early cucumber and melon hot-beds; which, without the aid of occaſional linings, would not retain ſufficient heat to forward their reſpective plants, &c. to proper perfection.

The dung for this purpoſe ſhould be of the beſt freſh horſe ſtable kind, moiſt and full of a ſteamy lively heat, being prepared in the manner deſcribed under HOT-*Bed*, and in proper quantity to make the lining ſubſtantial, as 15 or 18 inches wide, and as high as the dung of the hot-bed; as, when too ſlender, they do not effect the intended purpoſe, eſpecially in early beds, or when the heat is conſiderably decreaſed.

And in early hot-bed work, care ſhould be taken, according to the extent of the bed or beds and ſeaſon of the year, to allot and reſerve a ſufficiency of dung for linings: early beds in very cold weather will generally require more ſubſtantial and frequent linings than later made beds in the advanced ſpring months; and ſome hot-beds, for ſlight or temporary uſes, juſt to raiſe plants for two or three weeks, will ſometimes require but very little or no linings. Hot-beds made late, as in the beginning or any time in May, will need but very trifling linings, or ſome not at all, except in particular uſes, as when plants are rather backward in growth, the weather cold, and the bed declined much in heat, when, probably, even in May, or beginning of June, a final moderate lining may become neceſſary.

It is neceſſary that the requiſite linings ſhould always be applied to the reſpective hot-beds in proper time, which may be aſcertained by examining the ſtate of heat; not letting them decline too conſiderably before they are applied, but to continue always a moderately lively heat, but never violent. Linings are ſometimes applied by degrees, raiſing them only half-way at firſt; adding more in height in a few days, and thus proceeding till they are raiſed to the height of the hot-beds.

And in application of linings, it is generally neceſſary to line only one ſide at a time, commonly the back part of the bed firſt; and in a week or fortnight after, to line the front ſide, and both ends, if neceſſary; or in particular caſes of the hot-bed having ſuddenly declined, or been permitted to decreaſe very conſiderably in heat before applying the lining, to line both ſides moderately at once, about 12 or 15 inches in width, but only as high as the dung of the bed at firſt; being afterwards a little augmented by degrees, according as the dung of the lining ſettles.

The general requiſite thickneſs or ſubſtance of the linings is from 12 to 15 or 18 inches width in dung, and as high as the dung of the bed, or ſometimes a few inches higher: but for early beds of cucumbers, melons, or other plants of long continuance in hot-beds, they ſhould generally be laid from 15 to 18 inches in width at bottom, as conceived neceſſary, narrowing the width gradually upwards to 8, 10, or 12 inches at top, which may be raiſed at once to the full height of the dung of the bed, or a few inches higher up the ſide of the frame, to allow for ſettling: but with a ſtrong lining, great caution ſhould be uſed in raiſing it much above the dung of the hot-bed, eſpecially when made of very ſtrong, hot, ſteamy dung, for fear either of its throwing in a too ſtrong heat above to burn the internal earth of the bed, or imparting a copious rank ſteam to penetrate within the frame, which would ſteam-ſcald the tender plants which may be contained therein.

As ſoon as the linings are raiſed to the intended height, it is proper in general to lay a ſtratum of earth at top two inches thick, cloſe up to the bed or bottom part of the frame, ſloping a little outward to throw off the falling wet of rain, ſnow, &c.; which top-covering of earth is eſſential, both to keep the heat of the linings from eſcaping too conſiderably above, in order that it may be directed more effectually to its intended purpoſe of imparting its whole principal heat internally to the revival of that of the bed, and prevent the ſtrong ſteam ariſing immediately from the rank dung from entering the frame at bottom, or through any ſmall crevice, or at top, when the lights are occaſionally raiſed for the admiſſion of freſh air; as the rancid dung ſteam thus produced, without being moderated and corrected by firſt paſſing through a ſtratum of earth, if it ſhould enter within the frame conſiderably, would prove very pernicious to moſt plants, and be the total deſtruction of ſome particular kinds.

And conſtant care muſt be taken, that as the heat of the linings declines to any extent, they muſt, as juſt noticed, be renewed by a ſupply of freſh hot dung. This may ſometimes be effected by turning over, and ſhaking up the ſame dung mixedly together, directly forming it again into a lining: or ſome of the beſt or leaſt decayed or exhauſted parts of the old lining may only be uſed, mixing it up properly with a good ſupply of new dung, applying it immediately in a proper ſubſtantial lining as before. In either of theſe ways, freſh air is entangled, by which a new fermentation and heat is brought on. However, where the dung of the linings is greatly exhauſted, freſh dung ſhould moſtly be uſed in the renewal of the heat.

And linings of hot dung are ſometimes uſed ſubſtantially, in working ſome ſorts of forcing-frames, in raiſing early flowers and fruits, by applying the dung againſt the back of the frame, two or three feet in width at bottom, narrowing gradually to a foot and a half, or leſs, at the top, raiſing the whole according to the height of the frame, from four or five to ſix or ſeven feet; which heating conſiderably againſt the whole back of the frame, communicates the heat internally, by which the different plants are forwarded to early production; ſupporting the internal heat by renewing the linings, as already directed. See FORCING-*Frame*, and *Garden*-FRAME.

Linings of dung are alſo ſometimes uſed in ſupporting the heat of nurſery hot-beds for young pine-apple plants, and ſome other exotics of the hot-houſe or ſtove, both in dung and tan-bark hot-beds, under proper frames and glaſſes; as well as thoſe wintered in theſe detached hot-beds diſtinct from the hot-houſe, &c. in which a conſtant regular heat, almoſt equal to that of the ſtove, muſt be ſupported; ſo that, when the natural heat of the bed is on the decline, a ſtrong lining of hot dung muſt be applied, half a yard or two feet wide below, narrowing moderately upward, and continued on both ſides occaſionally: and as the heat of them ſubſides, it muſt be immediately renewed by a ſupply of freſh dung, either worked up with the beſt of that of the declined dung; or, if this be too much decayed, wholly of new: and thus the hot-beds maintained in a proper degree of heat from the autumn until the ſpring ſeaſon, when they become unneceſſary.

And the decayed dung of the different linings, when done with, becomes excellent manure for the kitchen-garden departments.

LINING, in *Maſt-Making*, denotes the marking of the length, breadth, or depth of any thing, according to deſign, by a cord, rubbed with white or red chalk, faſtened at the extremities, and forcibly pulled up in the middle, or towards one end, then let fall perpendicularly, if meant to be ſtraight, or thrown ſideways to form a curve. Accuracy in the latter performance requires practice.

LININGS, in *Sail-Making*, ſignify the canvas ſewed on the backs and middle of a ſail, to ſtrengthen it.

LINITAN, in *Geography*, a ſmall iſland in the Eaſt

Indian ſea, five miles north from the iſland of Serangan, to which it belongs. S. lat. 5° 36′. E. long. 125° 21′.

LIN-KIANG, a city of China, of the firſt claſs, in the province of Kiang-ſi, ſituated on the banks of the river Yu-ho. Its ſoil is good, and the climate is healthful; but it is ſo much deſerted that the Chineſe ſay, "one hog would be ſufficient to maintain the whole city two days." Four cities of the third claſs belong to its diſtrict. One of its villages is the general mart for all the drugs ſold in the empire; and this circumſtance gives it ſome degree of celebrity. N. lat. 27° 58′. E. long. 115°.

LINKIO, in *Botany*, a kind of water-plant among the Chineſe, the fruit of which is of a triangular pyramidical form, prominent every way, with a green thick rind, that grows reddiſh towards the apex, and, when the fruit is dried, grows black. The internal ſubſtance is exceeding white, its taſte like that of the cheſnut, three or four of which it equals in bulk. The plant is found in ſtanding waters, and has very ſlender leaves, that ſpread themſelves over a large extent on the ſurface of the water, and the fruit lies concealed under water in great numbers.

LINKIOPING, in *Geography*, a ſmall and neat town of Sweden, in Eaſt Gothland, ſituated on the river Stœng, near lake Roxen; containing an epiſcopal palace, a cathedral, and the houſe which is the reſidence of the governor of Eaſt Gothland. It has three churches and a public ſeminary; 96 miles S.W. from Stockholm. N. lat. 58° 26′. E. long. 15° 18′.

LINKNESS, a cape of Scotland, on the N.W. coaſt of the iſland of Stronſa; 1½ mile S.W. of Huipſneſs. N. lat. 59° 4′. E. long. 0° 26′.

LINLEY, John, in *Biography*, an eminent muſic profeſſor and organiſt, long reſident at Bath, where he had ſerved an apprenticeſhip under Chilcot, the organiſt of that city. Linley loved muſic, was a ſtudious man, equally verſed in the theory and practice of his art. Having a large family of children, in whom he found the ſeeds of genius had been planted by nature, and the gift of voice, which, in order to cultivate, he pointed his ſtudies to ſinging, and became the beſt ſinging maſter of his time, if we may judge by the ſpecimens of his ſucceſs in his own family. He was not only a maſterly player on the organ and harpſichord, but a good compoſer, as his elegies and ſeveral compoſitions for Drury-lane theatre evinced. His ſon, Thomas, who was placed under Nardini at Florence, the celebrated diſciple of Tartini, was a fine performer on the violin, with a talent for compoſition; which, if he had lived to develope, would have given longevity to his fame. Being at Grimſthorpe, in Lincolnſhire, at the ſeat of the duke of Ancaſter, where he often amuſed himſelf in rowing, fiſhing, and ſailing in a boat on a piece of water, in a ſquall of wind, or by ſome accident, the boat was overſet, and this amiable and promiſing youth was drowned at an early age, to the great affliction of his family and friends, particularly his matchleſs ſiſter, Mrs. Sheridan, whom this calamity rendered miſerable for a long time; during which, her affection and grief were diſtilled in verſes of the moſt ſweet and affecting kind on the ſorrowful event. The beauty, talents, and mental endowments of this "Sancta Cæcilia rediviva," will be remembered to the laſt hour of all who heard, or even ſaw and converſed with her. The tone of her voice and expreſſive manner of ſinging were as enchanting as her countenance and converſation. In her ſinging, with a mellifluous toned voice, a perfect ſhake and intonation, ſhe was poſſeſſed of the double power of delighting an audience equally in pathetic ſtrains, and ſongs of brilliant execution, which is allowed to very few ſingers. When ſhe had heard the Agujari, and the Danzi, afterwards Madame Le Brun, ſhe aſtoniſhed all hearers by performing their bravura airs, extending the natural compaſs of her voice a fourth above the higheſt note of the harpſichord, before additional keys were in faſhion. Mrs. Sheridan died at Briſtol in 1792.

Mrs. Tickel, her ſiſter, was but little inferior to her in beauty and talents, and Mr. Linley's other daughters continued to excite the admiration of all who knew them, in a manner worthy of the family from which they ſprung.

Mr. Linley, the father of this neſt of nightingales, from being aſſiſtant manager of Drury-lane theatre, lived to become joint patentee, and, for ſome time, ſole acting manager; in which capacity, he gave more ſatisfaction, and eſcaped cenſure, public and private, by his probity and ſteady conduct, more than is often allowed to the governor of ſuch a numerous and froward family. This worthy and ingenious man died November 1795.

LINLITHGOW, in *Geography*, a royal borough and county town of Linlithgowſhire, or Weſt-Lothian, Scotland. It is ſituated on the road between Edinburgh and Stirling, at the diſtance of 16 miles from the metropolis. This town has claims to conſiderable celebrity, both on account of the connection of its hiſtory with ſome of the moſt important tranſactions of the kingdom, and of the noble remains of former magnificence with which it is adorned. As the reader will find mentioned in the following article, the name of this place is purely of Britiſh origin, and peculiarly deſcriptive in its application. During the reign of David I., Linlithgow formed a part of the royal demeſnes, and had a caſtle and a grange, at which that monarch and his ſucceſſors frequently reſided. When Alexander III. died, an event which happened before this town obtained its charter, it was governed by two bailies, as we learn from a writ addreſſed to them by Edward I., dated the 28th of Auguſt 1296, requiring them to make payment of ſome arrears, due to the king of Norway, by the firm of the town. In the year 1298, the ſame monarch encamped his army on the height immediately to the eaſt of Linlithgow on the night before the battle of Falkirk, in which the celebrated patriot, ſir William Wallace, was defeated through the treachery of Cumming. This town was formerly a place of very conſiderable commerce, opulence, and ſplendour, but all theſe advantages began gradually to decay, after the union of the two crowns, in the perſon of James VI. It once had an excluſive right of trade from the water of Cramond to the mouth of the Avon. Blackneſs caſtle was then aſſigned to it as a port, and at this place many warehouſes were erected, ſome of which are ſtill ſtanding. A cuſtom-houſe was likewiſe ſituated here, till removed in the laſt century to Borrowſtowneſs, through the intereſt of the Hamilton family.

The period at which Linlithgow was firſt conſtituted a royal borough by charter is uncertain, but it has doubtleſs exiſted in that capacity from a very early period. In the reign of David I. it is declared by act of parliament one of the principal burghs of the kingdom. Since that time it has received ſeveral charters, all of which were confirmed in 1540 by a writ of *Novodamus* from James V. The government of this town at preſent is veſted in a provoſt, four bailies, a dean of guild, twelve merchant counſellors, and the deacons of the eight incorporated trades. The principal manufacture now carried on is that of leather: ſhoemaking is a thriving buſineſs. The woollen trade is alſo conſiderable, and about a mile from the town there has lately been eſtabliſhed a very extenſive bleach field, which gives employment to nearly 300 perſons.

The preſent condition of Linlithgow, with reſpect to exterior view, is much inferior to what it formerly was.

From the antiquity of many of the houſes, the whole exhibits, at firſt ſight, a ruinous and decayed appearance. There are, however, a number of good buildings ſtill to be found. It conſiſts chiefly of one ſtreet, extending nearly a mile in length, from eaſt to weſt. This is interſected by a variety of ſmaller ſtreets or lanes. The ruins of the palace ſtand on a riſing ground, immediately overlooking the town. They are evidently the remains of a once magnificent and ſuperb manſion. The ſituation of theſe ruins is extremely fine, and ſuch as, in ancient times, would render it well calculated for defence. The eminence on which it is ſituated runs a conſiderable way in an extenſive lake, which conduces greatly to the ornament both of the town and caſtle. The firſt foundation upon this ſpot is ſaid to have been at leaſt coeval with the period of the Gadeni. There ſeems reaſon to believe it was afterwards the ſcite of a Roman ſtation. Fordun ſays that Edward I. erected a *pile* here in 1300. This, however, is doubtful, as it is unqueſtionably true that there was a royal reſidence here before that period, which cannot be ſuppoſed to have been unfortified in thoſe times. It is very probable that this monarch only repaired it for his reception in 1301, previous to paſſing his Chriſtmas in it, which he did that year. During the civil diſſentions between Bruce and Baliol, this caſtle was taken by ſtratagem, through the means of one Binnoch or Binny, who ſecretly favoured the cauſe of Bruce. Binnoch, being accuſtomed to ſupply the fortreſs with hay, was well known, and had free acceſs at all times. Under theſe circumſtances he propoſed to Bruce to conceal ſome armed men in his cart, which ſhould be apparently loaded with hay. Theſe being admitted, ſecured the guards, and made themſelves maſters of the place. For this ſervice Binnoch was rewarded with ſome lands in the neighbourhood. In the reign of Edward III. this caſtle was again ſeized by the Engliſh. In 1424 it was deſtroyed by fire, as well as the greater part of the town. The name of the perſon by whom the former was rebuilt is unknown. It became a fixed royal reſidence ſoon after the acceſſion of the houſe of Stewart to the throne of Scotland; and was ſeveral times aſſigned as a jointure-houſe to the queens of that kingdom. In October 1488, this palace was delivered to the rule of lord Hailes and Alexander Home, two of the principal leaders of the rebellion againſt James III., one of the mildeſt monarchs that ever graced a throne, whoſe melancholy fate every feeling heart muſt pity and bewail. In 1517 it was ſeized by Stirling and his followers, who had attempted to aſſaſſinate Melburne; but was ſoon afterwards retaken by aſſault by De la Baſtie, the regent's lieutenant, when the aſſaſſins were fortunately ſecured. James V. reſided for the moſt part in this palace, during his minority. The battle of Linlithgow was fought on the 4th September 1526, with the view of reſcuing that prince from the domination of the earl of Angus. In this action, the earl of Lennox, the friend of James, was ſlain, after quarter given, by ſir James Hamilton. To the laſt-mentioned monarch and to James VI. this palace was indebted for much of its magnificence and grandeur. Over the inſide of the grand gate there formerly ſtood a ſtatue of pope Julius II. with the triple crown, who ſent a conſecrated ſword and helmet to James V. This piece of ſculpture, after eſcaping for more than a century the fury of the reformiſts, ultimately fell a ſacrifice to the pious zeal of a blackſmith. The whole palace is conſtructed of hewn ſtone, and covers about an acre of ground. It has in the centre a handſome ſquare, one ſide of which is more modern than the others, having been built by James VI. In one portion of this building is a very ſuperb room, 90 feet long, 30 feet 6 inches wide, and 33 high. At one end is a gallery with three arches, probably intended for muſicians. The parliament-chamber, in which the unfortunate queen Mary was born on the 8th December 1542, has likewiſe been an elegant apartment. The whole was kept in good repair till the year 1746, when being uſed as a barrack, a great part of it was accidentally burnt by the king's troops. Since that period it has been ſuffered to fall into ruins. The church of Linlithgow, which is appended to the palace, is a very fine building. Some of the windows are particularly beautiful. In this edifice the aiſle is ſtill ſhewn, in which James IV. is ſaid to have ſeen an apparition, warning him of the impending fate of the battle of Flowden, in which that monarch and the flower of his nobility were ſlain. As there is no doubt but a perſon in an unuſual habit did accoſt that prince, when attending the evening ſervice in this aiſle, it is ſuppoſed to have been a ſtratagem of the queen's, to diſſuade him from his intended enterprize againſt England, which a credulous and ſuperſtitious age converted into a ſupernatural and prophetic admonition. The church is adorned with a handſome ſpire, ſurmounted with an imperial crown. A number of ſtatues formerly decorated the outſide, but were all deſtroyed by the reformers, except that of the patron of the church, the archangel St. Michael. The houſe from which Hamilton ſhot the regent Murray, in the reign of queen Mary, is ſtill ſtanding. This murder is one of the moſt deliberate recorded in the annals of hiſtory. The town-houſe, erected in 1668, is a commodious and elegant ſtructure. In front, but at ſome diſtance from it, there was formerly an antique croſs, ornamented with groteſque figures, and having eight ſpouts at different elevations, from which the water was poured. This having become much decayed, a new one, of ſimilar conſtruction, has lately been erected. Linlithgow anciently poſſeſſed a variety of religious eſtabliſhments. In 1290 the inhabitants founded a convent of Carmelites, or White friars, on an eminence ſouth of the town, ſtill called Friars' Brae. St. Magdalen's on the eaſt, ſituated at the foot of Pilgrim's hill, was formerly a *hoſpitium*, or place of entertainment for ſtrangers. The Dominican or Black friars had likewiſe a monaſtery here. All theſe buildings were demoliſhed by the earl of Argyle, lord James Stewart, and John Knox, when they viſited Linlithgow in their progreſs of reform. Linlithgow rendered itſelf conſpicuous by the part its inhabitants took in the grand rebellion. It had its full ſhare in the miſeries of that diſtracted period. The ſolemn league and covenant was publicly burned here, on the anniverſary of the reſtoration in 1662, by the inhabitants themſelves, without any authority from government. This town ranks as the ſixth among the royal boroughs of Scotland. Since the union, it has been aſſociated with Lanark, Selkirk, and Peebles, in the privilege of ſending one repreſentative to parliament. Winzet, the famous polemical antagoniſt of John Knox, was maſter of the Linlithgow ſchool, when choſen by the Catholic clergy to defend their principles and rights.

The pariſh of Linlithgow is about five miles in length, and three in breadth: it is in general well cultivated and encloſed. Coal is abundant in different parts of it, but no pits are at preſent wrought. There is likewiſe plenty of lime-ſtone, but free-ſtone is ſcarce. Copper-ore has been found in one ſpot; and in the ſouthern extremity there is a ſilver mine, which is ſaid to have been formerly wrought to great advantage. The population of the whole pariſh, according to the parliamentery returns of 1801, amounted to 3594 perſons; the houſes were eſtimated at 746. Sinclair's Statiſtical Account of Scotland.

LINLITHGOWSHIRE, or WEST LOTHIAN, a county on the ſouthern ſhore of the Frith of Forth in Scotland.

land. It is ſeparated from Edinburghſhire on the eaſt and ſouth-eaſt by the rivulets Briech and Amow, except at Midcalder, where the latter county intrudes ſomewhat more than a mile into Linlithgowſhire. On the weſt it is divided from Stirlingſhire, firſt by the Linn-burn, and after its junction with the Avon, by that river, till it diſcharges itſelf into the Forth. A part of Lanarkſhire forms the boundary on the ſouth-weſt, while the waters of the Forth waſh its coaſt for the extent of fourteen miles on the north. The form of this county is that of an irregular triangle. Its medium breadth from north to ſouth is little more than ſeven miles, and its medium length about ſixteen. It contains nearly 112 ſquare miles, or 57,008 Scottiſh acres. The pariſhes amount to 13 in number, compriſing, according to the parliamentary returns of 1800, a population of 17,844 perſons.

The aſpect of this county, except towards the ſouth, where it conſiſts chiefly of moor-moſs and moraſs, is that of a level and well cultivated diſtrict, diverſified by a variety of ſmall hills: theſe are moſt numerous in the middle and weſtern parts of the county. Beginning at Bowden, the more remarkable of them form a range which runs through the centre of the county in an oblique direction from north-weſt to ſouth-eaſt. In the northern diſtrict they are leſs elevated than towards the middle and weſtern parts, and are more variouſly diſtributed. In general they are both uſeful and ornamental, nearly the whole of them affording abundant paſture; many of them being clothed with woods; and not a few of them containing valuable minerals.

Soil and Climate.—This county exhibits a great diverſity of ſoils, as well as variableneſs of climate. Almoſt every kind of clayey ſoil is to be found in different parts of it. About 7000 acres are compoſed of light gravel and ſand, and nearly the ſame extent of that ſpecies which is uſually called loam. The high rocky land extends to about 10,000 acres, and the moſſes to ſomewhat better than 1000. Such parts of this county as border on the Forth, have a temperate and an excellent climate. The upper or ſouth-weſtern part, however, is not ſo much favoured. Its elevated ſituation with the proximity of the moors and moſſes, either in this county or the neighbouring one of Lanark, render it bleak and damp during the greater part of the year.

The lands of this county are poſſeſſed by between thirty and forty landholders whoſe eſtates vary from 200*l.* to 6000*l.* *per annum*, beſides a few of inferior rental. About a third part of the county conſiſts of wood and paſture lands, or is laid down with artificial graſſes. The cauſe of this great proportion of paſture graſs ſeems to be the vicinity of Edinburgh. The agriculture of this county is ſimilar to that of the other Lothians. The upper portions are the pooreſt, but even in the higheſt moors of that diſtrict, art and induſtry are making rapid changes and improvements. The grub-worm is perhaps more deſtructive in this than in moſt other counties. This inſect generally begins its depredations in May or June, eſpecially if the lands have been formerly in graſs, or over-run with moſs, and the crops are ſtunted, which is apt to be the caſe, from the dry eaſt winds which prevail during theſe months. Not above one-ſixth of the whole county remains unincloſed. Great attention is paid to the forming of plantations, particularly in the neighbourhood of gentlemen's ſeats, which tend in no ſmall degree to enrich the ſcenery of this cultivated diſtrict. The ſhores of the Forth are peculiarly ornamented both by nature and art. Barnbeugle park, the ſeat of the earl of Roſeberry, is laid out with plantations, formed in the very beſt taſte, and in a manner well calculated to ſhelter the ſoil, and exhibit the aſpect of the country around to great advantage. On the coaſt, Linlithgowſhire riſes ſuddenly into a ridge adorned by culture and well wooded. From hence weſtward by the ancient ſeat of the Dundas family, and by Hopetoun-houſe, a ſeries of views are to be met with not inferior to any in the kingdom. The ſcenery in the immediate neighbourhood of Queensferry is peculiarly fine, the Forth here forming a narrow ſtrait, which expands ſuddenly on both ſides into an extenſive bay, with richly ornamented banks. At various points of the coaſt the views are different, the water aſſuming the appearance of a lake, a noble river or broad ſea, according to the ſituation from which it is ſeen. In one ſpot, a little diſtance from the ſhore, ſtands Hopetoun-houſe, one of the moſt ſuperb and magnificent ſeats in this kingdom. It is ſituated on a noble and extenſive lawn, ſtretching to the diſtance of more than a mile from the front of the houſe, and forming a ſort of terrace along the banks of the Forth, which winds round it, and preſents the view of a wide extenſive lake, interſperſed with iſlands, and enlivened by a variety of ſhipping. Behind the houſe the ground is more various, breaking into hills, vallies, and promontories, which ſhoot into the Forth. To a conſiderable diſtance the grounds ſeem well wooded and encloſed; the houſe itſelf is flanked with a noble plantation, which ſerves to ſhelter it from the northern blaſts. At the extremities of this vaſt and magnificent ſcenery a variety of mountains ariſe of different forms and at different diſtances. In ſhort, every thing the eye can contemplate in the whole ſcene, or its appendages, is great and noble. The ſituation of the houſe, and its architecture, are alſo equally objects of admiration. It was planned and begun by the celebrated architect ſir William Bruce, and finiſhed by Mr. Adams. Some of the apartments are grand and ſpacious, but they are in general of moderate ſize, which is perhaps the only defect of its contrivance. It abounds with paintings.

With the exception of free-ſtone and coals, there are no minerals of any importance in the county. In the Balligate-hills there was formerly a valuable lead mine, but being now ſought in vain is ſuppoſed to be exhauſted. A free-ſtone quarry, in the neighbourhood of Queensferry, is one of the fineſt in the kingdom. More than three acres have been already excavated. This ſtone is exported in great quantity, both as materials for building, and in the ſhape of grinding-ſtones. Coal abounds in different parts of the county; but is chiefly wrought in the neighbourhood of Borrowſtowneſs. Here is one of the moſt extraordinary coal mines in the world: it extends under the Forth half way acroſs. Formerly there was a building, or moat, about half a mile from the ſhore, where there was an entry down into the pit formed under the ſea. This building being in the ſhape of a quay, veſſels were brought along ſide of it, and loaded with the coals raiſed from the pit and depoſited here. This mine was extremely profitable, but at laſt an unexampled high tide overwhelmed the whole, before the colliers could effect their eſcape. This did not diſcourage the daring adventurers. A new mine was opened, and continues to be wrought at this day to a great extent. For the purpoſe of rendering the coal in the upper parts of this county more extenſively uſeful, it has been propoſed to cut a canal from Glaſgow to Edinburgh, which might likewiſe bring to the eaſtward, at a cheap rate, a portion of the treaſures contained in the hills of Lanarkſhire. To theſe uſeful productions of the mineral deſcription in this county, may be added iron-ſtone, whin-ſtone, grey granite, and ſhell marle. On the ſouth ſide of Dundas-hill is a baſaltic rock, 250 yards in length, and 60 or 70 feet high. The maſſes are in an irregular ſtate, formed like pillars, ſeparated by channels; but not a few of them exhibit regular and well defined priſms. The ſtone of which theſe are compoſed is of a light blueiſh colour.

The royal boroughs in this county are Linlithgow and Queensferry. The former is the ſhire town, and ſituated in the interior of the county. The latter ſtands on the coaſt of the Forth, about nine miles weſt from Edinburgh. It was formerly of more importance than at preſent; it being now totally deſtitute of trade. A particular account of theſe boroughs will be found under their reſpective names.

Borrowſtowneſs, or Bo-neſs, is the principal ſea-port town in this county. It is a borough of barony, governed by a bailiff appointed by the duke of Hamilton. The houſes in this place are low and crowded, and much injured in appearance, by the ſmoke of the numerous ſalt pans with which it abounds. The produce of theſe pans, and of the coal-works in the neighbourhood, are the chief articles of export from this town. The harbour is conſidered very ſafe. About thirty ſail of ſhipping belong to perſons reſident on the ſpot. Many others frequent this harbour in the courſe of trade. The imports are uſually tallow, hemp, timber, flax, and flax-ſeed. The herring-fiſhery is carried on here, but, being hazardous and precarious, ſcarcely deſerves notice in mentioning the commerce of this port. Kineel houſe, belonging to the duke of Hamilton, is beautifully ſituated on the ſhore of the Forth, not far from the town. The village of Bathgate ſtands on the ſouthern declivity of the hills which bear its name, and form a part of the range already mentioned, as running through the centre of the county. Here, as well as in the village of Whitburn, ſituated on the moſt ſouthern road between Edinburgh and Glaſgow, a number of weavers are employed by the Glaſgow manufacturers. At preſent neither of theſe places is of much importance: but in the event of the propoſed canal, formerly noticed, being carried into effect, it is not improbable they would ſoon riſe into conſiderable diſtinction. Beſides theſe, there are few other villages in this county which do not, however, require particular notice.

Among the antiquities of this county is the termination of the celebrated Roman barrier, or wall of Antoninus. It enters Linlithgowſhire near the village of Inner Avon, and proceeds by Kineel houſe to the village of Carriden, behind the church of which, it is probable, the laſt or nineteenth fort, counting from the Clyde, was ſtationed, though no remains of the work can now be diſcovered beyond the incloſures of Grange. Two miles eaſt from Carriden, and one and three quarters weſt from Abercorn, is Blackneſs caſtle, which, from its ſituation with regard to the wall, ſeems not improbably to have been the Roman port on the Forth. In Abercorn pariſh, on a point north-eaſt from the church, Abercorn caſtle was formerly ſituated. It was one of the ſtrong holds of the Douglaſes, and was taken by ſtorm, after a long ſiege, by James II. during his conteſt with that family. After this it was never repaired, and Buchanan mentions it as a ruin in his time. The moſt ancient monaſtery in Scotland was ſituated here, as we learn from the venerable Bede, after whoſe time it is not mentioned in hiſtory. In Torphechen pariſh was a houſe for the knights of St. John; it was founded by king David I. This preceptory was a place of refuge, or ſanctuary. In the church-yard is a ſtone with a St. John's croſs on it, and four ſimilar ones at the diſtance of a mile each. This pariſh is alſo diſtinguiſhed by four great ſtones, ſituated about a mile eaſt of the village, which are ſaid to have been a Druidical temple. In Kirkliſton pariſh is another remarkable ſtone, known to the inhabitants by the name of the *Cat ſtone*. It is four feet and a half high, and eleven feet and a half in circumference. The form is that of an irregular priſm. On one ſide is the following inſcription, rudely, but deeply, cut, the explanation of which has puzzled many antiquaries. "IN OC. TUMVLO JACI UETTA DUICTA." The church of Dalmeny may likewiſe be ranked among the antiquities of this county. Concerning the date of its erection nothing is known. Its architecture is of that middle ſort which has received the appellation of Saxon. It is a ſmall building, apparently with Grecian windows, but upon inveſtigation, the ſhafts are found to be diſproportionate. The eaſtern portion of this church is vaulted with ſemicircular arches, having mouldings chiefly in the form of ſtars and other decorations. Sinclair's Statiſtical Account of Scotland. Chalmer's Caledonia.

LINNÆA, in *Botany*, ſo called in honour of the great Swediſh naturaliſt, (ſee LINNÆUS,) appears by the journal of his Tour to Lapland to have been choſen by himſelf to commemorate his own name, when he gathered it at Lykſele, May 29, 1732. Former botaniſts had called this elegant and ſingular little plant *Campanula ſerpyllifolia*; but Linnæus, proſecuting the ſtudy of vegetables on the only certain principles, the ſtructure of their parts of fructification, ſoon found this to conſtitute a new genus. He reſerved the idea in his own breaſt, till his diſcoveries and publications had entitled him to botanical commemoration, and his friend Gronovius, in due time, undertook to make this genus known to the world. It was publiſhed by Linnæus himſelf in the *Genera Plantarum*, ed. 1, in 1737, and the ſame year in the *Flora Lapponica*, with a plate, being moreover mentioned in the *Critica Botanica*, p. 80, as "a humble, deſpiſed, and neglected Lapland plant, flowering at an early age," like the perſon whoſe name it bears. Ord. *Aggregatæ*, Linn. *Caprifolia*, Juſſ.

Gen. Ch. *Cal.* Perianth double; that of the fruit inferior, of two or four leaves; the outermoſt of which are oppoſite and minute; the others elliptical, concave, erect, hiſpid, cloſed around the germen, permanent; that of the flower (the proper one) ſuperior, of one leaf, in five erect, narrow, acute, equal, deep ſegments. *Cor.* of one petal, above twice as long as its perianth, bell-ſhaped, its border in five rather deep, obtuſe, nearly equal diviſions. *Stam.* Filaments four, awl-ſhaped, inſerted into the bottom of the corolla, two of them much the ſmalleſt; anthers compreſſed, verſatile. *Piſt.* Germen roundiſh, inferior; ſtyle thread-ſhaped, ſtraight, the length of the corolla, inclining; ſtigma globoſe. *Peric.* Berry dry, ovate, of three cells, clothed with the hiſpid glutinous perianth of the fruit, deciduous. *Seeds* roundiſh, two in each cell.

Eſſ. Ch. Calyx double; that of the fruit of two or four leaves; that of the flower ſuperior, in five deep diviſions. Corolla bell-ſhaped. Berry dry, of three cells.

Obſ. The two outer or ſmaller leaves of the inferior calyx are often wanting. When preſent they are like the inner ones in ſhape, though ſmaller in ſize, and ſtand like them cloſe to the germen, being totally diſtinct from the bracteas, which are a little remote from them, lanceolate and acute.

1. L. *borealis*. Linn Sp. Pl. 880. Fl. Suec. 219. t. 1. Fl. Lapp. ed. 2. 214. t. 12. f. 4. Engl. Bot. t. 433. Fl. Dan. t. 3. (Campanula ſerpyllifolia; Bauh. Prodr. 35.)— Native of dry ſtony moſſy ancient fir woods, in Sweden, Siberia, Ruſſia, Switzerland, Scotland, and North America, flowering in May and June. Linnæus deſcribes it in his Lapland Tour, v. 1. 20, as clothing maſſes of ſtones,

being interwoven with ivy, in a pictureſque manner. It was firſt diſcovered in Britain, June 2d, 1795, by the late profeſſor James Beattie of Aberdeen, in an old fir wood at Mearns in that county.

The *root* is fibrous and perennial. *Stems* trailing, creeping, perennial, woody, round, leafy, ſomewhat hairy, often reddiſh, a little branched, very long and ſlender. *Leaves* evergreen, oppoſite, ſtalked, roundiſh or ovate, veiny, crenate in the fore-part, paler beneath, bearing a few ſcattered hairs on the upper ſide. Flowering *branches* erect, three or four inches high, with a pair or two of leaves near the bottom, naked above, terminating in two equal *flower-ſtalks*, with a pair of ſmall leaves at their origin, and each bearing one drooping *flower*, accompanied by two ſmall, lanceolate, ſlightly remote, oppoſite *bracteas*, which, like the ſtalks, calyx and germen, are clothed with glandular viſcid hairs. The *flowers* are of a delicate pink, eſpecially within, being pale white or yellowiſh externally. They are ſaid in the *Flora Suecica* to be very fragrant at night, ſmelling like Meadow-ſweet. An infuſion of the leaves, with milk, is eſteemed a ſpecific, among the Swedes, in rheumatic and ſciatic diſorders. The inhabitants of Weſt Bothnia cure painful complaints in the feet of their ſheep, with a cataplaſm or fomentation made of this herb. The ſmoke of it when burnt is thought by the Norwegians beneficial in the ſcarlet fever; and its decoction in the itch.

This is the only known ſpecies of *Linnæa*. The right honourable ſir Joſeph Banks is poſſeſſed of a drawing, made by an artiſt who was employed many years ago to delineate plants in the Eaſt Indies, which repreſents a plant anſwering to the ſame generic characters, but of which no ſpecimens having ever been ſeen, the drawing is ſuppoſed to be a forgery. The younger Linnæus, when in England, was much intereſted by the ſight of it, but endeavoured in vain to aſcertain its truth.

LINNÆAN *Syſtem of Botany*. See BOTANY, FLOWERS, and SEXUAL *Syſtem*.

LINNÆUS, CHARLES, afterwards VON LINNÉ, in *Biography*, the moſt eminent of modern naturaliſts, whoſe labours and abilities rendered his favourite ſcience of Botany firſt more philoſophical, and then more popular, than it had ever been in any other age, was born at Råſhult, in the province of Smaland, in Sweden, May 13th, old ſtyle, 1707. His father Nicholas Linnæus was aſſiſtant miniſter of the pariſh of Stenbrohult, to which the hamlet of Råſhult belongs, and became in proceſs of time its paſtor or rector; having married Chriſtina Broderſon, the daughter of his predeceſſor. The ſubject of our memoir was their firſt-born child. The family of Linnæus had been peaſants, but ſome of them, early in the 17th century, had followed literary purſuits. In the beginning of that century regular and hereditary ſurnames were firſt adopted in Sweden, on which occaſion literary men often choſe one of Latin or Greek derivation and ſtructure, retaining the termination proper to the learned languages, as Melander, even when the name itſelf was not taken from thence, as Retzius. A remarkable Linden-tree, *Tilia europæa*, growing near the place of their reſidence, is reported to have given origin to the names of Lindelius and Tiliander, in ſome branches of this family; but the above-mentioned Nicholas is ſaid to have firſt taken that of Linnæus, by which his ſon became ſo extenſively known. Of the taſte which laid the foundation of his happineſs as well as his celebrity, this worthy father was the primary cauſe. Reſiding in a delightful ſpot, on the banks of a fine lake, ſurrounded by hills and valleys, woods and cultivated ground, his garden and his fields yielded him both amuſement and profit, and his infant ſon imbibed, under his auſpices, that pure and ardent love of nature for its own ſake, with that habitual exerciſe of the mind in obſervation and activity, which ever after marked his character, and which were enhanced by a rectitude of principle, an elevation of devotional taſte, a warmth of feeling, and an amiableneſs of manners, rarely united in thoſe who ſo tranſcendently excel in any branch of philoſophy or ſcience, becauſe the cultivation of the heart does by no means ſo conſtantly as it ought keep pace with that of the underſtanding. The maternal uncle of Nicholas Linnæus, Sueno Tiliander, who had educated him with his own children, was alſo fond of plants and of gardening, ſo that theſe taſtes were in ſome meaſure hereditary. The young Charles, as he tells us himſelf, was no ſooner out of his cradle, than he almoſt lived in his father's garden. He was ſcarcely four years old when he heard his father deſcant, to a rural party, on the diſtinctions and qualities of ſome particular plants, culled from the flowery turf on which they were ſeated, and this firſt botanical lecture was ever after remembered as an epocha in his ſcientific life. He never ceaſed to enquire of his father concerning the names and properties of all the productions of the garden and the fields, that he could poſſibly procure; nor did the economy of inſects, even at this early period, eſcape his attention. His youthful inaptitude for retaining the names of natural objects, ſometimes tired and diſpleaſed his inſtructor, whoſe wholeſome authority in time corrected this defect, and perhaps early prevented his falling into the error of thoſe deſultory ſpeculators of nature, who have agreed to deſpiſe that methodical and didactic preciſion of ideas, which, for want of early diſcipline, they could never attain. The memory of Linnæus, indeed, like his powers of perception, was naturally good, and his ſight was always remarkably acute. The vivacity and brilliant expreſſion of his eyes are ſaid to have laſted through life, and indeed are diſplayed in moſt of his portraits.

Theſe flowery ſtudies however were obliged to give way, in ſome meaſure, to leſs agreeable occupations, and unhappily the private tutor proved a man of leſs winning manners than the beloved parent. Thus at ſeven years of age grammar had but an unequal conteſt with botany in the mind of the young ſtudent. Nor was he much more fortunate when removed in 1717 to the grammar-ſchool of Wexio, the maſter of which, as his diſguſted pupil relates, "preferred ſtripes and puniſhments to admonitions and encouragements." Such a ſyſtem was near extinguiſhing all the talents it was intended to cultivate, and when the youth was committed, two years afterwards, to the care of a more judicious and amiable private tutor than before, the horrors of the rod ſeem ſtill to have predominated over his taſte for learning. In 1722 he proved competent, nevertheleſs, to be admitted to a higher form in the ſchool, and his drier ſtudies were now allowed to be intermixed and ſweetened with the recreations of botany. In 1724, being 17 years of age, he was removed to the ſuperior ſeminary, or *Gymnaſium*, and his deſtination was fixed for the church. But the original inclinations of his mind, and its early prejudices, here grew but the more apparent. He had no taſte for Greek or Hebrew, ethics, metaphyſics or theology; but he devoted himſelf with ſucceſs to mathematics, natural philoſophy, and a ſcientific purſuit of his darling botany. The *Chloris Gothica* of Bromelius, and *Hortus Upſalienſis* of Rudbeck, which made a part of his little library, were calculated rather to fire than to ſatisfy his curioſity; while his Palmberg and Tillands might make him ſenſible how much more than they had accompliſhed ſtill remained to be done. His own copies of theſe books, uſed with the utmoſt care and neatneſs, are now before us. His literary reputation however made ſo little progreſs, that, when his father paid a viſit to Wexio, in 1726, his tutors, like the ſapient inſtructors of Newton at Cambridge, gave him up as a hopeleſs dunce. They adviſed that he ſhould be put apprentice to a ſhoemaker, tailor, or ſome other handicraft trade, rather than be forced to purſue an object, for which he was evidently unfit. Fortunately, the diſappointed parent met with a better counſellor in Dr. Rothmann, the lecturer on natural philoſophy, who encouraged him to hope much from the inclination of his ſon to natural knowledge and practical obſervation, and recommended that he ſhould be directed to the ſtudy of medicine. This good advice was ſupported with the gratuitous offer of taking the young man into his own houſe, for the year during which he was ſtill to remain at the *Gymnaſium*, which was gladly accepted. The worthy preceptor gave his pupil a private courſe of inſtruction in phyſiology on the Boerhaavian principles, and was rewarded by the ſucceſs of his endeavours. He firſt ſuggeſted to Linnæus the true principles upon which botany ought to be ſtudied, founded on the parts of fructification, and put the ſyſtem of Tournefort into his hands, in the knowledge of which he made a rapid progreſs. Its very imperfections proved uſeful, in prompting him to attempt ſomething more complete hereafter.

In 1727 Linnæus was matriculated at the univerſity of Lund, having, on the 19th of Auguſt, undergone with credit the examination of the Dean, and even of the Profeſſor of Eloquence, Papke. He devoted himſelf to the ſtudy of medicine, lodging at the houſe of a phyſician, Dr. Stobæus, whoſe library and muſeum of natural hiſtory, afforded the greateſt delight and aſſiſtance to his ardent mind, and the ſtudy of which often robbed him of ſeveral hours of his natural repoſe. In the ſame houſe was a German ſtudent named Koulas, eager like himſelf for inſtruction, and their friendſhip was mutually beneficial. Dr. Stobæus being infirm in health and ſpirits, Linnæus was allowed to relieve him occaſionally from the labours of his profeſſion, and ſoon became a great favourite. While botanizing in the country, in the ſpring of 1728, our young naturaliſt met with that accident, whatever it was, which he always attributed to the ſting or bite of his ſuppoſed *Furia infernalis*, an animal whoſe exiſtence has been doubted by many perſons, and by ſome poſitively denied. We need not here repeat what is ſaid under the article FURIA. His pupil Solander has recorded ſeveral caſes of this accident or diſeaſe, and deſcribes the animal as if he had ſeen it, in the *Nova Acta Upſalienſia*, v. 1. 55. In the enſuing ſummer Linnæus paſſed the vacation under his paternal roof. Here he met with his former patron Rothmann, by whoſe advice he was induced to quit Lund for Upſal, as a ſuperior ſchool of medicine and botany. But the ſlender ſupport which his father could afford him, a capital of about 8*l.* ſterling, being totally inadequate, he was, in this new ſituation, reduced to the greateſt neceſſity. Private pupils were not to be procured by a poor unknown ſtudent. He was obliged to truſt for chance to a meal; and when he relates that he had no way of mending his ſhoes but by folded paper, ſeems to have felt the want even of the cobler's education which had been recommended to him. He had offended his old friend Stobæus by quitting Lund, and though he had brought with him a ſplendid Latin teſtimonial, from the Rector of that univerſity, in which he was called *Politiſſimus ornatiſſimuſque dominus*, and was declared "to have conducted himſelf with no leſs diligence than correctneſs, ſo as to gain the affection of all who knew him," he ſeems to have obtained nothing more than a royal ſcholarſhip, which was conferred upon him on the 16th of December, but of the value of which we are not informed. It appears however by the above account to have been totally inſufficient for his maintenance. He nevertheleſs did not relax in his ſtudies; but attended the lectures of the younger Rudbeck, then Profeſſor at Upſal, as well as the medical ones of Profeſſor Roberg: and made critical manuſcript remarks upon all that he ſaw and heard.

In the autumn of 1729 his botanical taſte and application raiſed up for him a new and very eſtimable patron, in the learned Dr. Olaus Celſius, Profeſſor of Divinity, who met with him by chance in that academical garden, the fame of which he was deſtined hereafter to immortalize. This gentleman had then been intent, for above 30 years, upon the illuſtration of the plants mentioned in the Holy Scriptures, on which he publiſhed a very celebrated work in 1745, having travelled to the Eaſt on purpoſe to render it more perfect. He ſoon diſcovered the merit of Linnæus, took him under his protection, and allowed him the full uſe of his own rich library. The friendſhip of ſuch a man ſoon procured him further advantages. The ſon of Profeſſor Rudbeck, and other young men, became his private pupils, by which his finances were improved. Nothing however ſeems to have been recollected with ſo much ſatisfaction to himſelf, in relating the events of this part of his life, as his intimate ſcientific friendſhip with Peter Arctedius, who afterwards called himſelf Artedi, and became ſo famous in the knowledge of fiſhes and of umbelliferous plants. They paſſed ſome time together ſubſequently in Holland, when Linnæus witneſſed the melancholy fate of his friend, who was accidentally drowned at Amſterdam; of which he has prefixed ſo pathetic an account to the *Ichthyologia* of Artedi, publiſhed by his means.

During his ſtudies, under the roof of Celſius, Linnæus met with a review of Vaillant's treatiſe on the Sexes of Plants, which firſt led him to conſider the importance, and great varieties of form, of the ſtamens and piſtils, and thence to form a new ſcheme of arrangement founded on thoſe eſſential organs. He drew up an eſſay in oppoſition to the librarian of the univerſity, who had publiſhed a work *de Nuptiis Plantarum*, and ſhewed it to Celſius, who communicated it to Rudbeck, and the performance was honoured with the high approbation of both. This led the way to his being appointed to lecture in the botanic garden, as an aſſiſtant or deputy to the latter, whoſe advanced age rendered ſome relaxation neceſſary. The lectures of Linnæus began in the ſpring of 1730. He had previouſly ſolicited from the Profeſſor the humble appointment of gardener to the univerſity, which was refuſed, only on the ground of his being fit for a better ſituation. Now finding himſelf authorized to take the direction of the garden, he reformed and greatly enriched it. He was taken into the houſe of Rudbeck, as tutor to his younger children, and by this means had the uſe of a very fine collection of books and drawings. His mornings being devoted to the duties of his ſtation, his evenings were ſpent in preparing ſome botanical works. It was now that he began to write his *Bibliotheca Botanica*, *Claſſes Plantarum*, *Critica Botanica* and *Genera Plantarum*, though theſe books were not given to the world till about ſeven years afterwards, when he printed them in Holland, during his ſtay there.

A new object now engaged all the attention of our emulous young naturaliſt. The converſations of Rudbeck, concerning the natural hiſtory of Lapland, and the curioſities he had ſeen there, excited an irreſiſtible deſire in Linnæus to viſit the ſame country. To this he was perhaps the more immediately prompted, by ſome little circumſtances, which made his reſidence at Upſal uncomfortable. Theſe were, the jealouſy of Dr. Roſen, who was ambitious of ſucceeding Rudbeck whenever his Profeſſorſhips ſhould become vacant, and who by his ſucceſs as the only practiſing phyſician at Upſal, was likely to prove a formidable rival; as well as ſome domeſtic chagrin, which he thus relates. "The faithleſs wife of the librarian Norrelius lived at this time in Rudbeck's houſe, and by her Linnæus was made ſo odious to his patroneſs, that he could no longer ſtay there."—In the end of the year 1731 he retired to his native place, and ſoon received, from the Academy of Sciences at Upſal, an appointment to travel through Lapland, under the Royal authority, and at the expence of the Academy.

After a viſit to Lund in the ſpring of 1732, Linnæus ſet out from Upſal, May 12th, on his Lapland expedition. He travelled on horſeback, but ſlenderly provided with baggage, and after viſiting the Lapland alps on foot, and deſcending to the coaſt of Norway, of which he has given a moſt pictureſque and ſtriking deſcription, returned by Tornea, and the eaſt ſide of the Bothnian gulf, to Abo, and ſo to Upſal, which he reached on the 10th of October, having performed a journey of near 4000 Engliſh miles. The particulars of his intereſting expedition have lately been given to the public, in an Engliſh tranſlation of the original journey written on the ſpot, illuſtrated with wooden cuts from his own ſketches, making two octavo volumes. This document, a faithful tranſcript of his own mind, and written ſolely for his own uſe, gives a moſt amiable and reſpectable idea of the character and acquirements of this celebrated man, at this period of his life.

Having learned the art of aſſaying metals during ten days' reſidence at the mines of Biorknas, near Calix, in the courſe of his tour, he next year gave a private courſe of lectures on that ſubject, which had never been taught at Upſal before. The jealouſy of Roſen, however, ſtill purſued him; and this rival deſcended ſo low as to procure, partly by intreaties, partly by threats, the loan of his manuſcript lectures on botany, which Linnæus detected him in ſurreptitiouſly copying. Roſen had taken by the hand a young man named Wallerius, who afterwards became a diſtinguiſhed mineralogiſt, and for whom he now procured, in oppoſition to Linnæus, the new place of *adjunct*, or aſſiſtant, in the medical faculty at Lund. But the baſeſt action of Roſen, and which proved envy to be the ſole ſource of his conduct, was, that having married the niece of the archbiſhop, he obtained, through his lordſhip's means, an order from the chancellor to prevent all private medical lectures in the univerſity. This, for which there could be no motives but conſcious inferiority and malice, deprived Linnæus of his only means of ſubſiſtence, and the ſtudents of any information which might endanger their reverence for his rival. He is ſaid to have been ſo exaſperated, as to have drawn his ſword upon Roſen, an affront with which the latter choſe to put up, as, doubtleſs, became the proſperous nephew of an archbiſhop; but Linnæus cannot be exculpated of having, for ſome time afterwards, indulged feelings of paſſionate reſentment, and even of meditated revenge. Theſe, however, his better principles and diſpoſitions, after a while, entirely ſubdued, and Roſen, towards the cloſe of his life, was glad of the medical aid of the man he had in vain endeavoured to cruſh.

Diſappointed in his views of medical advancement, Linnæus turned his thoughts more immediately to the ſubject of mineralogy. In the end of the year 1733, he had viſited ſome of the principal mines of Sweden, and had been introduced to Baron Reuterholm, governor of the province of Dalarne, or Dalecarlia, reſident at Fahlun. This place Linnæus has perpetuated in the memory of botaniſts, by his *Lichen Fahlunenſis*, a production more reſembling ſome ramification of the neighbouring copper ores, than any thing of vegetable origin. At the perſuaſion, as well as at the expence, of the governor, he travelled through the eaſtern part of Dalecarlia, accompanied by ſeven of his ableſt pupils, and the unpubliſhed journal of his tour exiſts in his library. At Fahlun he gave a courſe of lectures on the art of aſſaying, which was numerouſly attended, and here he firſt became acquainted with Browallius, then chaplain to the governor, afterwards biſhop of Abo. This judicious friend adviſed Linnæus to take his doctor's degree, in order to purſue the practice of phyſic, in which he had already at Fahlun met with much ſucceſs, and he further recommended him to aim at ſome advantageous matrimonial connection. Dr. John Moræus, a phyſician of the place, though at firſt not prepoſſeſſed in favour of our young adventurer, whoſe medical ſucceſs had encroached on his own, allowed him to pay his addreſſes to his eldeſt daughter; but their union was for the preſent deferred.

In purſuit of the plan pointed out by Browallius, Linnæus, having ſcraped together about 15*l*. ſterling, now entered on his travels, with a view of obtaining his degree at the cheapeſt univerſity he could find, and of ſeeing as much of the learned world as his chances and means might enable him to do. In the beginning of the year 1735 he ſet out, after viſiting his father, lately become a widower, in company with another medical ſtudent, named Sohlberg. At Hamburgh his ſkill and honeſty unfortunately ſtood in his way. The brother of one of the burgomaſters was poſſeſſed of a ſpecimen of that reputed wonder, a Hydra with ſeven heads, the awe and admiration of all who beheld it, upon which its owner, in the true mercantile ſtyle, had fixed an enormous hypothetical value. His golden dream was deſtroyed by Linnæus, who proved the monſter to be artificial.

After a ſtay of eight days at Amſterdam, Linnæus proceeded to Harderwyck, where, having offered himſelf as a candidate, and undergone the requiſite examinations, he obtained his degree June 23, 1735. On this occaſion he publiſhed and defended a theſis, entitled *Hypotheſis Nova de Febrium Intermittentium Cauſâ*, in the dedication of which, to his *Mæcenates et Patrones*, it is remarkable that, among the names of Rudbeck, Rothmann, Stobæus, Moræus, &c. we find that of Roſen. The hypotheſis here advanced, moſt correctly ſo denominated, is truly Boerhaavian. Intermittent fevers are ſuppoſed to be owing to fine particles of clay, taken in with the food, and lodged in the terminations of the arterial ſyſtem, where they cauſe the ſymptoms of the diſorder in queſtion. If we ſmile at the theory, we cannot but admire the ingenuity with which it is ſupported, and the extent of the author's knowledge and obſervation; nor is the theory itſelf at all leſs reſpectable, than thoſe which make a figure in the humoral pathology, univerſally taught at that period, by ſome of the greateſt medical philoſophers of any age.

In Holland Linnæus became acquainted with Dr. John Frederick Gronovius (ſee GRONOVIUS), who aſſiſted him in publiſhing the firſt edition of the celebrated *Syſtema Naturæ*, conſiſting of eight large ſheets, in the form of tables; which edition is now a great bibliothecal curioſity. He alſo procured acceſs to the illuſtrious Boerhaave, who encouraged him to remain in Holland; but this advice could ſcarcely have been followed, had he not met with a patron in Burmann, of Amſterdam, who was then preparing his *Theſaurus Zeylanicus*, and who received Linnæus into his houſe, as his gueſt for ſome months, during which period he printed his

Fundamenta Botanica, a ſmall octavo of 36 pages, in the form of aphoriſms, which contains the very eſſence of botanical philoſophy, and has never been ſuperſeded nor refuted. The ſubſequent performances of the author himſelf, and of his followers, have been excellent, in proportion as they have kept to the maxims of this little book. After Linnæus had been a few months under profeſſor Burmann's roof, he was introduced by Boerhaave to Mr. George Clifford, an opulent banker, whoſe garden at Hartecamp was one of the richeſt in the world, and who thought himſelf happy in the opportunity of procuring ſuch a man to ſtudy and ſuperintend his collection, as well as to make known to the world any novelties it might contain. Linnæus was therefore removed to Hartecamp, where, as he ſays, "he lived like a prince," more glorious, no doubt, than an Aſiatic deſpot, in the innumerable vegetable tribes which daily offered their homage at his feet. With an ample library, as well as garden, at his command, in both which he had unlimited powers to ſupply any defects that he might diſcover, he had now the means of cultivating his beloved ſcience without reſtriction or impediment, and appears to have been truly ſenſible of the happineſs of his lot. He now wrote and printed his admirable *Flora Lapponica*, the plates of which were ſupplied by the contributions of a ſociety at Amſterdam. This work, one of the happieſt literary compoſitions of its author, is ſtrikingly characteriſtic of the ſtate of his mind at the time it was written. It is redundant in obſervation and reflection, on every ſubject which could be interwoven with its profeſſed object, conveyed in the moſt engaging ſtyle; a ſtyle independent of ſtudied phraſeology, flowing directly from the heart, and deriving its principal charm from the delight which the author takes in what he has to communicate. The enthuſiaſm with which his imagination retraces every idea of his Lapland expedition, turns the wild ſcenes of that country, even in the mind of his reader, into a paradiſe, inhabited by all that is innocent and good. His effuſions reſemble the longings of an exiled Swiſs; and are in fact incipient ſymptoms of that oppreſſion of the heart, which, after a while, rendered his abode in Holland, with all its ſcientific charms, no longer tolerable, to one born in the purer air of Sweden, and nurtured amongſt her Lapland alps.

The proſperous condition of Linnæus, under the patronage of Mr. Clifford, afforded him much more than a ſelfiſh gratification, when he met with his old friend Artedi, at Amſterdam, deſtitute of the means of proſecuting his ſtudies, obtaining his degree, or even of ſupporting himſelf with credit or decency. "He had ſpent all his money in London;" an accident not peculiar to a poor Swediſh ſtudent; and would now have been deſtitute but for the exertions of his friend, who recommended him to Seba, to whom the learning and abilities of Artedi were peculiarly ſerviceable, in completing the third volume of his magnificent *Theſaurus*, chiefly devoted to fiſhes. We have already alluded to the unfortunate cataſtrophe of this young man, and a ſhort ſketch of his life is given in its proper place. See Artedi.

In 1736, after having written his *Muſa Cliffortiana*, Linnæus was ſent by Mr. Clifford to England, and was introduced to the lovers and teachers of natural ſcience, at Oxford and London more eſpecially. Of his reception from the Sherardian Profeſſor, we have already ſpoken. (See Dillenius.) He was ſtrongly recommended by Boerhaave, in a letter which ſtill exiſts, to ſir Hans Sloane; but this indefatigable collector neither underſtood nor cared for thoſe improvements in botanic ſcience which he might have learned from his viſitor. Linnæus found more intelligent and communicative friends in Dr. Shaw, the oriental traveller, profeſſor Martyn the elder, the well-known Philip Miller, and the celebrated Peter Collinſon. (See Collinson.) Theſe men of true ſcience admired his genius and valued his friendſhip; they promoted his wiſhes by every means in their power, enriching him with books; and ſupplying him plentifully with plants, both for his own herbarium, and the garden of his patron at Hartecamp. He was much ſtruck with what he ſaw of London, and has celebrated it in an expreſſion which has often been repeated, calling this famous city the "*punctum ſaliens in vitello orbis.*" Of his obſervations on the natural hiſtory of this country, nothing is preſerved but a tradition, that the golden bloom of the furze on the commons near London, eſpecially Putney-heath, delighted him ſo much, that he fell on his knees in a rapture at the ſight. He was always an admirer of this plant, and laboured in vain to preſerve it through a Swediſh winter in his greenhouſe; as we in England are obliged to ſhelter the Cape ſhrub in a ſtove, though it covers walls in the open air at Paris.

On his return to Holland, he continued the impreſſion of his *Genera Plantarum*, which appeared in 1737. In October, 1736, he was made a member of the Imperial Academy *Naturæ Curioſorum*, by the title, according to the cuſtom of that body, of Dioſcorides ſecundus. He was now tempted by Boerhaave to undertake a botanical expedition to the Cape of Good Hope and to America, at the public expence, and flattered with the expectation of a Profeſſorſhip in Holland at his return; but he neither choſe to encounter the hazards of the undertaking, nor to give up his proſpects at home. He would not however leave the benefactor to whom he owed ſo much, till he had accompliſhed all that was to be expected from him. He printed in 1737 the *Viridarium Cliffortianum*, an octavo catalogue of his friend's garden, diſpoſed according to his own ſexual ſyſtem; of which he publiſhed, later in the ſame year, at Leyden, an exemplification under the title of *Methodus Sexualis*, in which all the known genera of plants are ſo arranged by name only. This year alſo produced his magnificent *Hortus Cliffortianus*, in folio, in which all the plants of Mr. Clifford's collection, whether living or dried, are enumerated, with many deſcriptions and highly intereſting remarks, an almoſt complete detail of ſynonyms, and ſome of the moſt exquiſite plates ever ſeen in any book. This ſplendid volume was not publiſhed, but only given away by Mr. Clifford. It was begun and completed in nine months. In the intervals of this labour the *Critica Botanica*, an octavo volume, was written and printed. This is an entertaining commentary and illuſtration of part of the *Fundamenta*, from ſection 210 to 324, relating to nomenclature and ſpecific characters. It is a book not ſo much known as it deſerves, being very rare. Theſe ſevere labours however proved too much for the health of Linnæus, and he conceived that the autumnal air of Holland, as is very probable, did not agree with him. Though he had every luxury and indulgence at his command, and was careſſed by his patron, and by all who came near him, with the moſt flattering attentions, he longed to return to his native country. Having left Mr. Clifford, he could not refuſe his aſſiſtance for a while to Profeſſor Adrian Van Royen at Leyden, in the arrangement and deſcription of the garden there, which ſeems rather to have diſpleaſed his late patron, and not perhaps without reaſon, after the ſtrong inducements he had offered to retain him. Linnæus excuſed himſelf as well as he could, and while giving his aſſiſtance to Van Royen, compoſed and printed the *Claſſes Plantarum*, which is a complete view of all the botanical ſyſtems ever known. Here alſo he publiſhed his friend

Artedi's *Ichthyologia.* Boerhaave made another attempt to induce him to viſit ſome exotic regions, offering him a medical appointment at Surinam, which it is happy he did not accept. His friend and great favourite Bartſch, who was ſent in his ſtead, fell a ſacrifice to the climate, and to the neglect and ill uſage he received from the governor, as Linnæus has feelingly related in his *Flora Suecica,* under the genus *Bartſia.*

Linnæus remained at Leyden till the ſpring of 1738, when he had an intereſting interview with the great Boerhaave, then on his death-bed. "I have lived out my time," ſaid the venerable invalid. "I have done what I could, may God preſerve thee, from whom the world expects much more. Farewel!" Whether the climate of Holland cooperated with dejection of ſpirits in our young Swede, in conſequence of news he received reſpecting a rival in the affections of his miſtreſs, and in the eſteem of his intended father-in-law, or whether his literary labours were too unremitting, his departure was prevented by a very formidable intermittent fever. The ſkill of Van Swieten, and the renewed attentions of the amiable Clifford, who received him again under his roof with the moſt liberal and indulgent kindneſs, after ſome weeks reſtored him ſo far, that he was able, though ſtill weak, to ſet out on his journey. On reaching the more elevated country of Brabant, he felt in one day quite renovated, his whole frame being, as he expreſſes it, "freed from ſome great burthen." He carried a very handſome introductory letter from Van Royen to Anthony de Juſſieu, the phyſician, who made him acquainted with his brother, the famous Bernard de Juſſieu. (See JUSSIÆA.) He inſpected the botanic garden, the herbariums of Tournefort, Vaillant, the Juſſieus, &c.; viſited the neighbourhood of Fontainebleau, which he has celebrated for its *Orchideæ,* formed an acquaintance with Reaumur and other diſtinguiſhed naturaliſts, and was admitted a correſponding member of the *Academie des Sciences.*

How he converſed with Reaumur and others, who knew no language but their own, and for the ſame reaſon, how he contracted ſo cloſe a friendſhip with Mr. Collinſon at London, it is not eaſy to conceive. He confeſſes a peculiar inaptitude, and, we think, a blameable indifference, for the learning of languages, declaring in his diary that in all his travels he learnt "neither Engliſh, French, German, Laplandiſh, nor even Dutch, though he ſtayed in Holland three whole years. Nevertheleſs, he found his way every where, well and happily." By the journal of his Lapland tour, and other manuſcripts, it appears that Latin was ſufficiently familiar to him; and if faſtidious critics, who are not competent to follow his ideas, may ſometimes cenſure the ſtyle of part of his writings, they have chiefly taken that liberty with the *Amœnitates Academicæ,* not remarking the great variety of ſtyle in the eſſays which compoſe thoſe volumes, and which are chiefly written by the pupils whoſe inaugural diſſertations they were. The matter indeed was moſtly communicated by the Profeſſor, whoſe office it was to defend each theſis, in conjunction with the candidate, againſt all oppoſers. Thus theſe eſſays are always quoted as the works of Linnæus, though their language is rarely his own; and is indeed ſo various, that it could not be ſuppoſed all to come from one author.

After leaving Paris, Linnæus took his paſſage at Rouen for Sweden, and landed at Helſingborg, from whence he proceeded to Fahlun, viſiting his father for a few days in his way. His reception from the lady of his choice was favourable, and they were formally betrothed to each other. Before they could marry, it was neceſſary that ſome proſpect of an advantageous eſtabliſhment ſhould be diſcovered. Stockholm was thought a promiſing theatre for a young man of talents in the medical profeſſion, but talents are uſually what thoſe who employ a young phyſician, are of all things leaſt able to judge of. If fortune or prejudice do not ſtand his friend, the ſkill of Hippocrates, Celſus or Boerhaave will ſcarcely be diſcerned. The ſcientific merits of Linnæus were not overlooked, as he was unanimouſly choſen a member of the Upſal academy, the only one then in Sweden; yet the homage he had ſo lately received abroad, ſeems to have made him a little unreaſonable on this head, and he declares that he would certainly have quitted his native country, "had he not been in love." To this all-powerful deity therefore, and not to his merits, or to the wiſdom of his countrymen in diſcerning them, was Sweden, in the firſt inſtance, indebted for the poſſeſſion of her Linnæus. From his country however flowed his moſt abundant reward; for whatever emolument his matrimonial connexion might afford, it certainly brought him little happineſs or honour. After paſſing the winter of 1738 in the capital, he began to make his way in ſome departments of medical practice, ſo that by the following March he had conſiderable employment. At this time a plan was formed for eſtabliſhing a literary ſociety at Stockholm, which afterwards roſe to great eminence, and ſtill continues to flouriſh, having publiſhed numerous volumes of Tranſactions, in the Swediſh language. Triewald, Höpken and Alſtroem, (whoſe family was ennobled by the name of Alſtroemer,) were, with Linnæus, the firſt members: and the infant ſociety, being incorporated by royal authority, was augmented with all the moſt learned men of the country. Its objects were declared to be natural philoſophy, natural hiſtory in all its branches, chemiſtry, medicine, anatomy, ſurgery, mathematics, economy, commerce, arts and manufactures. So wide a range might have been feared to have endangered its ſucceſs; but though, in its progreſs, theſe various ſtudies have, from time to time, predominated by turns, they ſeem not to have claſhed with each other. Part of its tranſactions has been publiſhed in Latin at Venice, under the title of *Analecta Tranſalpina,* which is ſome reproach to other countries of Europe, where they are ſo very little known.

A moſt flattering mark of public approbation was, ſoon after, conferred on Linnæus, without any ſolicitation. Count Teſſin, marſhal of the Diet, which was then ſitting, gave him an annual penſion of 200 ducats from the board of mines, on condition of his giving public lectures on botany and mineralogy at Stockholm. The ſame nobleman alſo obtained for him the appointment of phyſician to the navy, and received him into his houſe. His practice now increaſed greatly among the nobility, and he found himſelf in ſo proſperous a condition that he would no longer delay his marriage, which took place at Fahlun, June 26. 1739. After a month he returned to Stockholm. He was, by lot, the firſt preſident of the new academy; and as that office was to be but of three months' duration, after the French plan, he reſigned it in September, and on that occaſion delivered an oration in Swediſh, on the wonderful Economy of Inſects, which was printed in the Tranſactions; and a Latin verſion of it may be found in the *Amœnitates Academicæ,* v. 2. His example was followed by all the ſucceeding preſidents.

The death of profeſſor Rudbeck in 1740, gave Linnæus a hope of ſucceeding to the botanical chair at Upſal, one of the greateſt objects of his ambition. The prior claims of his former rival, Roſen, on account of his ſtanding in the univerſity, could not however be ſet aſide. Wallerius alſo roſe up in oppoſition to the claims of Linnæus. It happened however that Roberg reſigned the profeſſorſhip of phyſic about this time, and by the exertions of count Teſſin, who applied to the chancellor, count Gyllenborg, a compromiſe took place. Roſen obtained the profeſſorſhip of botany, and Linnæus that of medicine, whilſt Wallerius gained only cenſure for the illiberality with which he had proſecuted his claims. By an amicable adjuſtment which was confirmed by authority, the two new profeſſors afterwards divided their official duties between them, ſo as beſt to ſuit the talents of each.

A war chancing to break out between Sweden and Ruſſia, Linnæus was apprehenſive that he ſhould be obliged to attend the fleet, inſtead of which, however, he received the much more agreeable order to travel through Æland, Gothland, &c. for the purpoſe of inveſtigating the natural hiſtory and produce of thoſe countries. He was accompanied by ſix of his pupils, and ſpent four months of the ſummer of 1741 in his expedition, of which an account was publiſhed at Stockholm in 1745; before he began his lectures at Upſal, to which place he removed in the autumn, he delivered a Latin oration "On the Benefit of travelling in one's own Country," printed in the 2d vol. of the *Amœnitates*, and tranſlated by Mr. Stillingfleet in his Miſcellaneous Tracts. This compoſition has been much and juſtly admired.

The next year Linnæus undertook the reform of the Upſal garden, a new green-houſe was erected; an old houſe of ſtone, built by the great Olaus Rudbeck, who, having ſuffered ſo much by fire, would not admit a bit of wood into the ſtructure, "was converted," as Linnæus ſays, "from an owl's neſt into a lodging fit for the Profeſſor." In 1743 the garden was in a ſtate to receive thoſe copious ſupplies of exotics, which the new Profeſſor, in conſequence of his extenſive foreign correſpondence, was enabled to procure. He was this year choſen a member of the academy at Montpellier. His reputation continued to increaſe both abroad and at home; he became ſecretary of the Upſal academy, and was employed on ſome public occaſions to do the honours of the univerſity. The death of his father-in-law obliged him to pay a viſit to Fahlun, but he ſeems to have gained little by this event, except the old medical library of Dr. Moræus, which ſtill makes a part of his own. In 1746 he travelled to Weſt Gothland; an account of his journey, which occupied two months, was publiſhed the following year.

In 1745 Linnæus publiſhed the firſt edition of his *Flora Suecica*, and in 1746 his *Fauna Suecica* came out. Theſe works are models for ſuch compoſitions, eſpecially their ſecond editions, publiſhed many years afterwards, with ſpecific names, and many valuable additions.

A medal of this diſtinguiſhed man was ſtruck by ſome of his friends in 1746, dedicated to count Teſſin. He ſoon after received the rank and title of Archiater, unſolicited, from the king, and was the only Swede choſen into the new-modelled academy of Berlin. All theſe honours, however, though he was by no means indifferent to ſuch, appear to have given him leſs delight at this moment, than the acquiſition of the herbarium made by Hermann in Ceylon, which an apothecary at Copenhagen unknowingly poſſeſſed. Being deſirous of becoming better acquainted with the nature of this collection, its owner was recommended to Linnæus, who ſoon diſcovered to whom it had originally belonged, and rejoiced at recovering a treaſure which had been ſuppoſed irrecoverably loſt. He laboured day and night, as he tells us, in examining the flowers, and hence originated his *Flora Zeylanica*, publiſhed at Stockholm in 1747. This herbarium, as well as that of Clifford, is now in the poſſeſſion of ſir Joſeph Banks.

The exertions, and domeſtic as well as foreign reputation, of Linnæus, had now rendered botany extremely popular in Sweden, and its intereſts were combined with thoſe of commerce in various diſtant expeditions and ſpeculations. Many of the principal merchants, as well as the nobility, had acquired a taſte for natural hiſtory, and were proud to further the views of their diſtinguiſhed Profeſſor, who was now conſidered an honour to the nation. Several of his moſt intelligent pupils were ſent to ſuch diſtant countries, as he thought moſt worthy to be explored; as the Eaſt Indies, China, North and South America, and the Holy Land. (See HASSELQUIST, KALM, and LŒFLINGIA.) Their diſcoveries enriched his works and his herbarium. The latter alſo received important and very intereſting communications from Gmelin and others, who had viſited Siberia, and the original collections of Magnol and Sauvages were tranſmitted from Montpellier. Gronovius alſo furniſhed many Virginian ſpecimens, gathered by Clayton. Such communications, from all parts of the world, grew more and more frequent as Linnæus advanced in life, as did alſo the academical honours which every literary body was proud to confer upon him. In 1749 appeared his *Materia Medica*, written in the ſame ſyſtematic and didactic ſtyle as the reſt of his works. Of this numerous editions have been publiſhed on the continent, but none with any additions or corrections from the author himſelf, though he has left behind him copious manuſcript notes on the ſubject. By the curious frontiſpiece of this book, one would ſuppoſe that he laughed in his ſleeve at the ſtate of medical practice in the world, though the body of the work proves he laboured very ſeriouſly to improve it. This year he travelled through Scania, &c. and, two years afterward, publiſhed an account of this tour, as he had done of the former. It is much to be regretted that theſe travels of Linnæus are not given to the world in a language more generally underſtood. There are German tranſlations of them, but we know of no others. He was this year rector of the univerſity, and it was memorable to him alſo for an attack of the gout, ſo violent as to endanger his life. He always attributed his reſtoration from this fit, and other ſubſequent ones, to his eating wood ſtrawberries, the only ſort, then at leaſt, known in Sweden. Of this fruit his ſervants were ordered to purchaſe, throughout the ſeaſon, all that were brought to his door, and it made a principal part of his diet.

To this attack of the gout, however diſtreſſing to the patient, the world is indebted for one of his moſt valuable and remarkable works, the *Philoſophia Botanica*. The ſubſtance of this book muſt have been comprehended in the mind of its author when he wrote his *Fundamenta Botanica*; of which it is profeſſedly a dilatation or exemplification, in the form of a commentary on each aphoriſm throughout. But, though he had long meditated on the ſubject of this publication, which embraces the whole range of botanic ſcience, and indeed all the principles of natural knowledge; he had made but a few notes, not being able to digeſt or ſelect his ideas, ſufficiently to his own ſatisfaction, to communicate them to others. This illneſs however prompted him to reſcue from the grave, to which he ſuppoſed himſelf haſtening, whatever might be of ſervice to thoſe he left behind; and his pupil Lœfling was employed, ſitting by his bed-ſide, to write down whatever the intervals of his ſufferings would allow him to communicate. The manuſcript afterwards received his own corrections, and the book came out in 1751.

About this period the queen of Sweden, Louiſa Ulrica, ſiſter to the great Frederick of Pruſſia, having a taſte for natural hiſtory, which her royal conſort king Adolphus Frederick alſo patroniſed, ſhewed much favour to Linnæus. He was employed in arranging her collection of inſects and ſhells, in the country palace of Drotningholm, or Ulrickſdahl, and was frequently honoured with the company and converſation of their majeſties, during his attendance there. The queen intereſted herſelf in the education of his ſon, and promiſed to ſend him to travel through Europe at her own expence. She alſo liſtened very graciouſly to any recommendation or petition of Linnæus, in the ſervice of ſcience; redeeming the papers and collection of Haſſelquiſt, and cauſing Kœhler to be ſent to the Cape of Good Hope; whoſe miſſion however was rendered abortive by the jealouſy of the Dutch, though he forwarded many curious inſects and plants to his maſter from Italy. Linnæus devoted ſome of his leiſure time in winter, to the arrangement of his friend count Teſſin's collection of foſſils, at Stockholm, of which an account in Latin and Swediſh, making a ſmall folio, with plates, came out in 1753. The reſult of his labours at Drotningholm was not given to the public till many years after, in 1764, when his *Muſeum Reginæ* appeared, in 8vo. being a ſort of *Prodromus* of an intended more ſplendid work, that was never executed. His moſt magnificent publication appeared in 1754, being a large folio, entitled *Muſeum Regis Adolphi Frederici*, comprehending deſcriptions of the rarer quadrupeds, birds, ſerpents, fiſhes, &c. of the king's muſeum, in Latin and Swediſh, with plates, and an excellent preface. This preface, one of the moſt entertaining and eloquent recommendations of the ſtudy of nature, that ever came from the pen of an enthuſiaſtic naturaliſt, was tranſlated into Engliſh by the writer of the preſent article, and firſt printed in 1786; appearing again, in a volume of *Tracts relating to Natural Hiſtory*, in 1798. The queen of Sweden took ſo much pleaſure in the converſation of her diſtinguiſhed naturaliſt, that ſhe allowed him his habitual indulgence of ſmoking, even in her apartments, that he might continue his labours with the more eaſe and ſatisfaction to himſelf. He was in every reſpect politely treated, as a viſitor to his royal miſtreſs, nor were his ſervices accepted, without ſuitable returns of royal munificence. Whether, however, he felt not ſo entirely at eaſe as in his own ſtudy, or his attention was diſtracted by a variety of objects, the *Muſeum Reginæ* is certainly not one of his moſt correct works, as thoſe who ſtudy its *Lepidoptera* and ſhells, with critical care, will not fail to diſcover.

In the mean while, this eminent man was preparing a laſting monument of his own talents and application, which even his rival Haller nobly denominates "*maximum opus et æternum*," the *Species Plantarum*, of which the firſt edition was printed in 1753, the ſecond in 1762, each in two volumes 8vo. The work is too well known to need any deſcription, but beſides its importance as a complete arrangement and definition, with all neceſſary indication of ſynonyms, of every plant of which its author had any ſatisfactory knowledge, it is ever memorable for the adaptation of ſpecific, or as they were at firſt called, trivial names. This contrivance, which Linnæus firſt uſed in his *Pan Suecicus*, a diſſertation printed in 1749, extended to minerals in his *Muſeum Teſſinianum*, and ſubſequently to all the departments of zoology, has perhaps rendered his works more popular than any one of their merits beſides. His ſpecific differences were intended to be uſed as names; but their unavoidable length rendering this impracticable, and the application of numeral figures to each ſpecies, in Haller's manner, being ſtill more burthenſome to the memory, all natural ſcience would have been ruined for want of a common language, were it not for this ſimple and happy invention. By this means we ſpeak of every natural production in two words, its generic and its ſpecific name. No ambiguous compariſons or references are wanted, no preſuppoſition of any thing already known. The diſtinguiſhing character of each object is moſtly ſtamped in its name; and if this perfection of the art cannot always be attained, the memory is aſſiſted, often very ingeniouſly, with collateral information, indicating the colour, the habit, or the qualities of the object of our examination. The philoſophical tribe of naturaliſts, for ſo they are called by themſelves and their admirers, do not therefore depreciate Linnæus, when they call him a nomenclator. On the contrary, they celebrate him for a merit which no other perſon has attained, and without which their own diſcoveries and remarks, of whatever value, would not be underſtood. Neither can ſome of his fellow labourers, in the diſcriminative department of natural ſcience, be juſtified, for either ſlighting this invention, or giving the credit of it to others. The method of Rivinus is not the ſame; as he deſigned his names for ſpecific characters, to which purpoſe they are neceſſarily, from their brevity, inadequate. Whatever may have been thought of the Linnæan trivial names at their firſt appearance, they are now in univerſal uſe, and their principle has been, with the greateſt advantage, extended to chemiſtry, of which the celebrated Bergman, the friend of Linnæus, originally ſet the example.

Theſe herculean literary labours, combined with the practice of phyſic, were more than the bodily conſtitution of Linnæus could ſupport. He was attacked with the ſtone, and had alſo, from time to time, returns of gout. He conſidered the wood ſtrawberry as a ſpecific for both diſorders, and they never greatly interfered with his comfort or his duties. On the 27th of April 1753, he received, from the hand of his ſovereign, the order of the Polar Star, an honour which had never before been conferred for literary merit. A ſtill more remarkable, if not more grateful, compliment was paid him not long after by the king of Spain, who invited him to ſettle at Madrid, with the offer of nobility, the free exerciſe of his religion, and a ſplendid botanical appointment. This propoſal was conveyed to him in a handſome letter by the duke of Grimaldi, then prime miniſter, and was as handſomely declined by Linnæus, who declared, that if he had any merits, they were due to his own country. This patriotic moderation received its juſt reward in November 1756, when he was raiſed to the rank of Swediſh nobility, and took the name of Von Linné.

The *Syſtema Naturæ* had already gone through nine editions in different countries. Its author had, for ſeveral years, a more ample edition of the animal department in contemplation, on the plan of his *Species Plantarum*, and this conſtituted the firſt volume of the tenth edition, publiſhed in 1758. The ſecond volume, which came out the following year, was an epitome of the vegetable kingdom. Here the genera appear with ſhort eſſential characters, and the ſpecies are noted by little more than their ſpecific differences, with few references and no indication of their native countries. This ſame great and important work appeared ſtill more enlarged, in a twelfth edition, in the year 1766: to this the Mineral kingdom was added in a third volume on the ſame plan with the firſt. We can readily pardon the ſelf-complacency of its author, when, in his diary written for the uſe of his friend Menander, he calls the *Syſtema Naturæ* "a work to which Natural Hiſtory never had a fellow." We may venture to predict that as this was the firſt performance of the kind it will certainly be the laſt; the ſcience of natural hiſtory is now become ſo vaſt, that no man can ever take the lead again as an univerſal naturaliſt.

The emoluments of Linnæus by his various publications were not great. He is reported to have ſold the copy-right of moſt of them for a ducat, (about nine and ſixpence,) a printed ſheet. His different appointments, however, for he ſoon laid aſide the general practice of phyſic, had raiſed him to a conſiderable degree of opulence. He purchaſed the eſtates of Hammarley and Söfja in 1758, for 80,000 dollars, above 2330*l.* ſterling. He choſe the former for his country reſidence, and there, ſome years afterwards, he lodged his muſeum, in a building of ſtone, ſecured from all danger by fire. There he received the viſits of diſtinguiſhed foreigners and admitted his favourite pupils; to ſeveral of whom he gave private courſes of Lectures, and completely laid aſide the ſtate of the nobleman and profeſſor while he diſcourſed with them on his favourite topics. In 1760 he could not reſiſt the temptation of writing in ſupport of his doctrine of the ſexes of plants, a handſome premium being offered that year by the Peterſburg academy, as it was ſuppoſed with a view to awaken his attention to the ſubject. His Diſſertation was printed, and was tranſlated into Engliſh in 1786, with notes, by the preſent poſſeſſor of his library. His patent of nobility did not receive his Majeſty's ſign manual till 1761, though it was antedated 1757. It was confirmed by the Diet in 1762, and he then took a coat of arms expreſſive of the ſciences he cultivated. That auguſt body honoured him with a ſtill more ſolid reward, upwards of 520*l.* ſterling, for what ſeems to have been the leaſt valuable of his diſcoveries, the art of producing pearls in the river muſcle. This was accompliſhed by wounding the ſhells in their natural ſituation, as appears by ſome ſpecimens illuſtrative of it in his muſeum, but the practice does not ſeem to have been proſecuted to any great extent.

He now became one of the eight foreign members of the French Academy of Sciences, an honour never before conferred on a Swede. Amid all his dignities however, his fondneſs for botany never declined; he records in his diary that having made many trials in vain to obtain the tea plant alive, he ſucceeded at length in 1763, adding "that God bleſſed him even in this point." His view indeed was patriotic as well as botanical, aiming at bringing this ſhrub into cultivation with us, ſo as, to uſe his own expreſſion, "to ſhut the gate through which all the ſilver went out of Europe." It is much to be regretted that, from ſome peculiarity in the conſtitution of this precious vegetable, all attempts to reconcile it to the climate of any part of Europe have proved of no avail, at leaſt as to any economical purpoſe.

In 1763 Linnæus was permitted to avail himſelf of the aſſiſtance of his ſon, now 21 years of age, in the labours of the Botanical Profeſſorſhip, and the young man was thus trained up for his future ſucceſſor. His eldeſt daughter was married to an officer in 1764. His worldly concerns appear to have been in a proſperous train, except that he ſuffered this year from a dangerous attack of pleuriſy; but it is pleaſing to read, in his private memorandums, the gratitude he expreſſes to his old rival Roſen, for his ſkill and attention during this illneſs, and the expreſſions of intimate regard by which they were now become attached to each other.

This year the ſixth edition, by far the moſt complete, of the *Genera Plantarum* was publiſhed, nor did its author ever prepare another. It was intended as a companion to the *Species Plantarum*, but was greatly ſuperſeded by the more conciſe and commodious ſhort characters of genera, given in the vegetable part of the *Syſtema Naturæ*. This laſt-mentioned part was ſubſequently prepared, under the inſpection of Linnæus, for publication by his pupil Murray of Göttingen, with the title of *Syſtema Vegetabilium*, edition 13th, and printed in 1774. A 14th edition, with additions from Jacquin and Thunberg, was publiſhed in 1784. Into theſe editions were interwoven the new ſpecies deſcribed by Linnæus in his firſt and ſecond *Mantiſſæ*, two little volumes, containing additions and corrections, by way of ſupplement to the *Species Plantarum*. In them we cannot help perceiving a decline of the wonted preciſion and genius of their author, eſpecially in the latter part of the ſecond *Mantiſſa*, many remarks in which are miſapplied, to plants different from what were intended, and the errors to which they give birth can be unravelled by the inſpection of the Linnæan herbarium only.

Though Linnæus declares, in his diary, that he gave up the general practice of phyſic, on his eſtabliſhment at Upſal, attending only his friends and the poor, he appears ever to have paid great attention to that noble and intricate ſcience. His lectures on medicine, dietetics, and the animal economy, were in high repute, nor is he at all behind-hand in commending his own abilities in this line. Though undoubtedly a great and ſagacious obſerver in every department of nature, he was in this ſomewhat too theoretical. If, however, he had peculiar ideas reſpecting the prevalence of the number five, his hypotheſes in general roſe much above the dull level of the humoral pathology in which he was educated; and when he applies his own didactic talents to illuſtrate medical theories, or any thing elſe, he is always ingenious, and as luminous as the ſubject will allow. His curious little *Clavis Medicinæ*, publiſhed in 1766, and his *Genera Morborum*, which appeared three years before, are not only ſtriking, but inſtructive. His idea of a ſyſtematic arrangement of diſeaſes by technical characters, was followed up and illuſtrated on a large ſcale, by his friend Sauvages of Montpellier; and the celebrated Dr. Cullen of Edinburgh, juſtly attributed to the Swediſh philoſopher the foundation of his own performance in this line. Such ſchemes of arrangement indeed can be conſidered merely as helps to the memory, and in themſelves altogether artificial. The abilities of Linnæus appear to the greateſt advantage in his claſſification of natural objects. He excelled in a happy perception of ſuch technical characters, as brought together things moſt naturally allied. Thus his ſexual diſtribution of plants, though profeſſedly artificial, is in many parts as natural as any that pretends to be ſo. Linnæus, moreover, was the firſt who perceived and declared the diſtinction between a natural and an artificial botanic ſyſtem, and he has laboured at the one as much as at the other. His lectures on the natural orders of plants were publiſhed, long after his death in 1792, from the notes of his pupils Giſeke and Fabricius, at Hamburgh. They evince his deep conſideration of a ſubject, then in the infancy of cultivation, the intricacy of which may well excuſe the frequency of error in the detail. In the zoological department, it is but juſtice to obſerve, that his claſſifications of birds and inſects are the moſt original as well as the beſt of the whole. In the former, as in the *Mammalia*, the organs of feeding lead the way to the moſt natural diſtinctions poſſible; but the author of this ſyſtem, which no one has yet attempted to ſuperſede, was well aware that the ſame principle would not hold good throughout, particularly with reſpect to inſects, whoſe deſtination, in their perfect ſtate, is not ſo much to take food, as to propagate their ſpecies. The mouth and its appendages are therefore, in this tribe, but of far ſubordinate conſequence; and Linnæus had recourſe to the more natural, as well as far more eaſy principles, deducible from the chief peculiarities of theſe animals, the differences in their wings, their ſtings, and their *antennæ*. His pupil Fabricius, for this reaſon, however able and ingenious in entomology, cannot be conſidered as fortunate or philoſophical, in applying his great preceptor's ſcheme of arrangement of quadrupeds and birds to inſects. Indeed, thoſe who have followed Fabricius in the detail of this ſtudy, declare, that he has rarely proceeded on his own plan, but, leaving the mouth in moſt caſes unexamined, has truſted to habit and general configuration, which certainly produce natural aſſemblages enough, and true to the Linnæan rules, but different from his own. The arrangement of fiſhes, by the relative poſition of their ventral fins, was a no leſs happy and original idea of the Swediſh naturaliſt; as pointing out their leading differences of form and habit, by a diſtinctive character, taken from a peculiar organ of their own. Shells he was long before he would ſtudy minutely at all, conſidering them merely as the houſes of particular animals, the knowledge of whoſe ſtructure and economy was, in a great meaſure, inacceſſible. At length, however, the uniformity of his plan obliged him to claſs theſe popular objects of admiration, in ſome way or other, and he has ſucceeded at leaſt as well as any of his fellow-labourers; though we are by no means inclined to juſtify ſome of his terms, which are borrowed from an anatomical analogy, not only falſe in itſelf, but totally exceptionable. This leads us to conſider a charge, often brought againſt this great man, of pruriency of phraſeology in many parts of his works. The moſt attentive contemplation of his writings has ſatisfied us that in ſuch inſtances he meant purely to be anatomical and phyſiological, and if his fondneſs for philoſophical analogies ſometimes led him aſtray, it was not in purſuit of any thing to contaminate his own mind, much leſs that of others. "Some of the deſcriptions of Linnæus," ſays a noble botanical author, "would make the moſt abandoned perſon bluſh." His lordſhip ought to have added, "*none but* the moſt abandoned." That the mind of Linnæus was ſimple and chaſte, as his morals were confeſſedly pure, is evinced by his Lapland Tour, written only for his own uſe, but which is now, as we have already mentioned, before the public. This is ſuch a picture of his heart, as will ever render any juſtification of his moral character, and any elaborate diſplay of his religious principles or feelings, alike ſuperfluous.

His apparent vanity, as diſplayed in his diary, publiſhed in Dr. Maton's valuable edition of Dr. Pulteney's *View of his Writings*, is perhaps far leſs juſtifiable. All we can ſay for him is, that this paper was drawn up for the uſe of his intimate friend Menander, as materials from which his life was to be written. If it be unbecoming, and indeed highly ridiculous in many inſtances, for a man to ſpeak as he does of himſelf, the juſtice and accuracy of his aſſertions, had they come from any other perſon, could in no caſe be diſputed.

As the habits of Linnæus were temperate and regular, he retained his health and vigour in tolerable perfection, notwithſtanding the immenſe labours of his mind till beyond his 60th year, when his memory began in ſome degree to fail him. In 1774, at the age of 67, an attack of apoplexy greatly impaired his conſtitution. Two years afterwards a ſecond attack rendered him paralytic on the right ſide, and materially affected his faculties. The immediate cauſe of his death, which happened January 10th, 1778, in the 71ſt year of his age, was an ulceration of the bladder. His remains were depoſited in a vault near the weſt end of the cathedral of Upſal, where a monument of Swediſh porphyry was erected by his pupils. His obſequies were performed, in the moſt reſpectful manner, by the whole univerſity, the pall being ſupported by ſixteen doctors of phyſic, all of whom had been his pupils. A general mourning took place on the occaſion at Upſal. His ſovereign, Guſtavus III. commanded a medal to be ſtruck, expreſſive of the public loſs, and honoured the Academy of Sciences at Stockholm with his preſence, when the eulogy of this celebrated man was pronounced there by his intimate friend Bäck. A ſtill higher compliment was paid to his memory by the king in a ſpeech from the throne, wherein his majeſty publicly celebrated the talents of his deceaſed ſubject, and lamented the loſs which his country had ſo recently ſuſtained. Various teſtimonies of reſpect were given to the merits of Linnæus in the different parts of Europe, even where rival ſyſtems or intereſts had heretofore triumphed at his expence. The celebrated Condorcet delivered an oration in his praiſe to the Pariſian Academy of Sciences, which is printed in its memoirs. We cannot wonder that his memory was cheriſhed in England, where he had long had numerous correſpondents, and where two of his moſt diſtinguiſhed pupils, Solander and Dryander, have, in their own talents and character, conferred ſingular honour upon their preceptor. Ten years after his deceaſe a new ſociety of naturaliſts, diſtinguiſhed by his name, was founded in London, and has ſince been incorporated by royal charter, whoſe publications, in ten quarto volumes of Tranſactions, ſufficiently evince that its members are not idle venerators of the name they bear. This name, in imitation of them, has been adopted by ſeveral ſimilar inſtitutions in other parts of the world.

The appellation of Linnæan Society was, with the more propriety, choſen by this Britiſh inſtitution, on account of the muſeum of Linnæus having fallen into the hands of its original projector, and hitherto only preſident. This treaſure, comprehending the library, herbarium, inſects, ſhells, and all other natural curioſities, with all the manuſcripts and whole correſpondence of the illuſtrious Swede, were obtained, by private purchaſe from his widow, after the death of his ſon in 1783. The authority which ſuch an acquiſition gave to the labours of the infant ſociety, as well as to all botanical and zoological publications, the authors of which have ever been allowed freely to conſult it, will readily be perceived. Nothing perhaps could have more contributed to raiſe up, or to improve, a taſte for natural ſcience, in any country.

Linnæus had by his wife Sarah Elizabeth, who ſurvived to extreme old age, two ſons and four daughters. His eldeſt ſon Charles ſucceeded him in the botanical profeſſorſhip; ſee the next article. The younger, John, died March 7, 1757, in the third year of his age. The marriage of his eldeſt daughter, Elizabeth Chriſtina, we have already mentioned. This lady is recorded as having diſcovered a luminous property in the flowers of the Naſturtium, *Tropæolum majus*, which are ſometimes ſeen to flaſh like ſparks of fire in the evening of a warm ſummer's day. Of the other daughters we know nothing materially worthy of record. The late Daniſh Profeſſor Vahl is reported, when a ſtudent, to have made an impreſſion on the heart of the youngeſt, which her father did not think proper to countenance, and which is ſuppoſed to have prevented his ſhewing that favour and encouragement to the young Dane, which his acuteneſs and zeal in botanical ſtudies certainly deſerved. Linnæus's Diary, publiſhed by Dr. Maton, with another in MS. of the early part of his life. Stoever's Life of Linnæus by Trapp. Aikin's General Biography. Various works of Linnæus. S.

LINNÆUS, or VON LINNÉ, CHARLES, the eldeſt, and only ſurviving, ſon of the preceding, was born January 20, 1741, at the houſe of his maternal grandfather at Fahlun. His father was anxiouſly deſirous of his excelling in natural hiſtory, more particularly botany, and after endeavouring, from his moſt tender years, to make him fond of flowers, committed him, when about the age of nine or ten, to the more particular care of ſome of his own moſt favourite pupils. By them he was taught the names of the plants in the Upſal garden, and ſuch of the principles of natural ſcience as were ſuited to his period of life, as well as to converſe habitually in Latin. He proved a docile and ready ſcholar, and appears to have given ſatisfaction to his father, who procured for him, at the age of eighteen, the appointment of Demonſtrator in the botanic garden, an office then firſt contrived on purpoſe for him. Having learned to draw from nature, he became an author at the age of twenty-one, publiſhing in 1762 his firſt *Decas Plantarum Rariorum Horti Upſalienſis*, the plates of which, in outline only, like thoſe of Plumier, were drawn by his own hand. Theſe are ſufficiently faithful and uſeful, if not ornamental. The deſcriptions are full and ſcientific. In 1763 another *Decas*, or collection of ten ſpecies, came out on the ſame plan. Whether the Upſal bookſellers did not encourage him to proceed, or for what other reaſon we know not, he never printed any more numbers under this title. In 1767 however, he publiſhed at Leipſic ten more plates and deſcriptions, like the above, entitled *Plantarum Rariorum Horti Upſalienſis Faſciculus Primus*. To this he was perhaps inſtigated by his friend Schreber, who, the year before, had given to the world a ſimilar work, deſcribing ten rare oriental plants, drawn by himſelf. But neither of theſe publications was ever extended to a ſecond *Faſciculus*. In 1763 he was nominated adjunct Profeſſor of Botany, with a promiſe, hitherto unexampled, that after his father's death, he ſhould ſucceed to all his academical functions. In 1765 he took his degree of Doctor of Phyſic, and began to give lectures.

His progreſs would probably have been happy, if not brilliant, but domeſtic chagrin ſapped the foundation of all his felicity, and damped his ardour in every purſuit. This aroſe from the conduct of his unnatural mother, another example of that rare and deteſtable depravity exhibited by the mother of Savage the poet. Not content with diſhonouring her huſband's bed, and making his home as uncomfortable as ſhe could, by the meaneſt parſimony and diſguſting petty tyranny, the wife of the great Linnæus conceived a hatred for her only ſon, which ſhe diſplayed by every affront and perſecution that her ſituation gave her the means of inflicting on his ſuſceptible and naturally amiable mind. According to Fabricius, ſhe forced her huſband, who by ſuch a conceſſion ſurely partook largely of her guilt and meanneſs, to procure the nomination of his pupil Solander to be his future ſucceſſor, in preference to his own ſon, and it was a part of her plan that he ſhould marry her eldeſt daughter. Solander, however, diſdained both the uſurpation and the bait, refuſing to leave England; and the miſguided father recovered his ſenſes and authority, cauſing his ſon, as we have ſaid above, to receive this truly honourable diſtinction. The mind and ſpirit of the young man nevertheleſs ſtill drooped, and even when he had attained his thirtieth year, he would gladly have eſcaped from his miſeries and his hopes together. The authority of the king was obliged to be exerted, at his father's ſolicitation, to prevent his going into the army. This meaſure of the parent was happily followed up by kindneſs and encouragement in his botanical purſuits, to which treatment the ſon was ever ſenſible, and he revived from his deſpondency before his father's death, which happened when he was thirty-ſeven years of age.

Though obliged by his mother to purchaſe, at her own price, the library, manuſcripts, herbarium, &c. which he ought by every title to have inherited, he roſe above every impediment, and betook himſelf to the uſeful application of the means now in his hands, for his own reputation and advancement. His father had already prepared great part of a third botanical Appendix, or *Mantiſſa*; from the communications of Mutis, Kœnig, Sparmann, Forſter, Pallas, and others. To this the younger Linnæus added thoſe of Thunberg from the Cape, which his father, "with half-extinguiſhed eyes," as Condorcet beautifully relates, had juſt been able to glance over, but not to deſcribe. Hence originated the *Supplementum Plantarum*, printed at Brunſwick, under the care of Ehrhart in 1781. The ingenious editor inſerted his own new characters of ſome genera of Moſſes; which Hedwig has ſince confirmed, except that ſome of the names have been juſtly rejected. This ſheet was, in an evil hour, ſuppreſſed by the mandate of Linnæus from London, where, at that period, the ſubject of generic characters of moſſes was neither ſtudied nor underſtood, whatever ſuperior knowledge was diſplayed concerning their ſpecies. The plants of the *Supplementum* are admitted into the fourteenth edition of the *Syſtema Vegetabilium* by Murray, and figures of ſome of the moſt curious have been publiſhed by the writer of this preſent article, in his *Plantarum Icones ex Herbario Linnæano.* Three botanical diſſertations alſo appeared under the preſidency of the younger Linnæus, on Graſſes, on *Lavandula*, and the celebrated *Methodus Muſcorum*, which laſt was the work, and the inaugural theſis, of the preſent Profeſſor Swartz of Stockholm. Theſe form a ſequel to the 186 ſimilar eſſays, which moſt of them compoſe the ſeven volumes of the *Amoenitates Academicæ*, the reſt being publiſhed by Schreber in three additional ones.

The ſubject of our memoir had always felt a ſtrong deſire to viſit the chief countries of learned and civilized Europe. For this purpoſe he was obliged to pawn his juvenile herbarium, made from the Upſal garden, to his friend Alſtroemer, for the loan of about fifty or ſixty pounds. He arrived at London in May 1781, and was received with enthuſiaſm by the ſurviving friends and correſpondents of his father, and was in a manner domeſticated under the roof of ſir Joſeph Banks, whoſe friendſhip, kindneſs, and liberality could not be exceeded; neither could they have been by any one more gratefully received. Here the ardent Swediſh viſitor had every aſſiſtance for the preparation of ſeveral works on which he was intent, as a ſyſtem of the *Mammalia*, a botanical treatiſe on the Lily and Palm tribes, and new editions of ſeveral of his father's ſtandard books. None of theſe however have yet been printed. An attack of the jaundice rendered half his ſtay in England uncomfortable as well as uſeleſs to him. He proceeded to Paris in the latter end of Auguſt 1781, accompanied by the amiable and celebrated Brouſſonet, with whom he became acquainted at London. His reception in France was not leſs flattering than what he had experienced in England. He was enriched with duplicates of Commerſon's plants from the herbarium of the excellent Thouin, which amounted to about 1100 ſpecies, and had never been communicated to any other foreigner. In the following ſpring he viſited Holland, tracing with filial piety every veſtige of his father's ſteps at Hartecamp and elſewhere, and receiving, as he had done at Paris and London, ample contributions for his herbarium, library, and muſeum of ſhells and inſects. The next place in which he made any ſtay was Hamburgh, where ſeveral of his own friends were already ſettled, and from hence he returned by Copenhagen and Stockholm, viſiting his friend Fabricius at Kiel, and his patron Baron

Alſtroemer at Gottenburgh, finally arriving at Upſal in February 1783. In his progreſs he had received ſeveral academical honours, as well as ample teſtimonies of ſcientific and perſonal reſpect, being a man of agreeable and unaſſuming manners, without vanity or oſtentation, though ſomewhat, perhaps not unduly, tenacious, that his own diſcoveries and performances ſhould not be confounded with any thing left behind by his father. But the career of this excellent man was cut ſhort by a bilious fever, which concluded with a ſtroke of apoplexy, November 1, 1783, in the forty-ſecond year of his age. His remains were interred with great ſolemnity on the 30th of the ſame month. His coffin was laid by the ſide of his father, and as the male line of the family concluded in him, their coat of arms was broken over the grave. After this ceremony the gardener of the univerſity ſtrewed flowers over the mingled aſhes of the father and the ſon. A funeral oration in Swediſh was pronounced by M. Von Schulzenheim, and was ſoon after publiſhed. This compoſition, partly tranſlated, and much enlarged, in the Engliſh edition by Trapp of Stoever's Life of Linnæus, has afforded much of the ſubſtance of this article, aſſiſted by ſeveral private communications.

The younger Linnæus is ſaid to have had naturally a ſtrong and vigorous frame of body, and to have inherited his father's keen and penetrating eyes, as well as his temper and active diſpoſition. He was greatly beloved by thoſe who knew him, and died generally reſpected and lamented. His muſeum and library reverted to his mother and ſiſters, as he had never been married; and the former inſtantly fixed her eyes on ſir Joſeph Banks, as the moſt likely perſon to purchaſe theſe relics at the high price, as ſhe thought it, of a thouſand guineas. On his refuſal, and by his kind recommendation and advice, they came into the hands where they now are. The ſale was precipitated before the return of the king of Sweden, then on his travels, leſt he ſhould oblige the heirs to diſpoſe of the whole at a cheaper rate to the Univerſity of Upſal. This would actually have been the caſe, as appears from the exertions made by his Majeſty on his return, who ſent a courier to the Sound, and a veſſel by ſea, to intercept the ſhip that was bearing away the prize. S.

LINNET, Linaria, in *Ornithology*, the denomination of a tribe of birds, which ſome authors have made a diſtinct genus, comprehending ſeveral ſpecies, which are uſually claſſed under the genus *Fringilla*. Thoſe who conſider them as a diſtinct genus, ſtate their characters to be theſe: the birds of it are ſomewhat ſmaller than the chaffinch; their general colour is a greyiſh-brown; their tail is a little forked, the outer feathers of it having white extremities; and they all ſing very ſweetly. We have in England four ſpecies of this bird.

1. The common brown linnet, the *Fringilla linota* of Gmelin, well known to every one. Theſe birds are much eſteemed for their ſong: they feed on ſeeds of different kinds, which they peel before they eat: the ſeed of the *linum*, or flax, is their favourite food, whence the name of the linnet tribe. See Fringilla *Linota*.

2. The *linaria rubra major*, or greater red-headed linnet, or greater redpole; the *Fringilla cannabina* of Linnæus. This has a fine red head, a grey neck, a duſky reddiſh-brown back, and its breaſt and belly are ſomewhat reddiſh. The female of this ſpecies, however, has no redneſs in its head or breaſt, but has ſomewhat of a greeniſh caſt on the brown of its back, and is yellowiſh on the breaſt, with ſome browniſh ſpots. It is a common fraud in the bird-ſhops in London, when a male bird is diſtinguiſhed from a female by a red breaſt, as in the caſe of this bird, to ſtain or paint the feathers, ſo that the deceit is not eaſily diſcovered, without cloſe inſpection. This ſpecies of linnet is frequent on our ſea-coaſts, and is often taken in flight time near London. It is a familiar bird, and becomes cheerful in five minutes after it is caught.

3. The *linaria rubra minor*, or leſſer red-headed linnet, or leſſer redpole; the *Fringilla linaria* of Linnæus. This is the leaſt of all the linnets, and on the back is of the ſame colour with the common linnet; the back part of its head is red, and alſo its breaſt, but the lower part of its belly is whitiſh. In this ſpecies, the female, as well as the male, has a red head, that of the male being ornamented with a rich ſhining ſpot of a purpliſh-red, and that of the female of a ſaffron colour; and both have their beaks much ſharper, and their feet and legs blacker than in the larger kind. This is a gregarious bird, whereas the larger ſpecies commonly flies ſingle. This ſeems to be the ſpecies known about London by the name of ſtone redpole.

4. The laſt ſpecies is the *linaria montana*, or *Fringilla montium*, or mountain linnet. This is the largeſt of all the linnets, according to Willughby's deſcription, though Mr. Pennant ſays that it is in ſize rather inferior to the common linnet. Its beak is very ſmall; its head and back are of the ſame colour with thoſe of the common linnet, and the feathers of its breaſt and belly are black, edged with white; the rump of the male is of a fine and beautiful red, and thus diſtinguiſhes it from the female. This ſpecies is common in Derbyſhire, but ſeems not ſo frequent in other places. However, it is taken in the flight ſeaſon near London with the linnets, and called a *twite*. It breeds, according to Mr. Pennant, only in the northern parts of our iſland. Ray and Pennant.

It is remarkable of the linnet, that when it builds in hedges, and when in furze-buſhes on heaths, in both which places the neſts are very common, they are made of different materials. When they build in hedges, they uſe the ſlender filaments of the roots of trees, and the down of feathers and thiſtles; but when they build in heaths, they uſe moſs, principally, for the outer part, finiſhing it within with ſuch things as the place will afford, chiefly with wool and hair. Theſe birds will have young ones three or four times a year, eſpecially if they are taken away before they are able to leave the neſts. They lay five whitiſh eggs, ſpotted like thoſe of the gold-finch.

When they are intended to be taught to whiſtle tunes, or to imitate the notes of any other bird, they are to be taken from the old ones when they are not more than four days old; for at this time they have no idea of the notes of the old ones, and will readily be taught to modulate their voice like any thing that is moſt familiar to their ears, and within the compaſs of their throats. The honourable Mr. Barrington obſerves, that in order to be certain that a neſtling will not have the call of its ſpecies, it ſhould be taken from the neſt when only a day or two old; though a bird of this age requires great trouble in breeding, and the chance is greatly againſt its being reared. There requires more care in the feeding them when they are taken thus young, than when they are left in the neſt till nearly fledged, but they will be reared very well upon a food half bread and half rapeſeed, boiled and bruiſed: this muſt be given them ſeveral times a day. It muſt be made freſh every day, and given them ſufficiently moiſt, but not in the extreme. If it be in the leaſt ſour, it gripes and kills them; and if too ſtiff, it is as miſchievous, by binding them up.

They muſt be hung up as ſoon as taken from the neſt, under the bird whoſe note they are intended to learn; or if they are to be taught to whiſtle tunes, it muſt be done by giving them leſſons at the time of feeding; for they will profit more while young in a few days, than in a long time afterwards, and will take in the whole method of their notes before they are able to crack hard ſeeds. Some have attempted to teach them to ſpeak, in the manner of the parrot, or other birds, and they will arrive at ſome ſort of perfection in it with great pains.

Mr. Barrington mentions a linnet, which being taken from its neſt when only two or three days old, almoſt articulated the words *pretty boy*, as well as ſome other ſhort ſentences. See SONG *of Birds*.

LINNICK, in *Geography*, a town of France, in the department of the Roer, and chief place of a canton, in the diſtrict of Aix-la-Chapelle, ſeated on the Ruhr; five miles N.N.W. of Juliers. The place contains 2086, and the canton 13,589 inhabitants. N. lat. 50° 57′. E. long. 6° 13′.

LINOCARPUM, in *Botany*, ſo called by Micheli, Nov. Gen. 22. t. 21, from the reſemblance of its fruit to that of *Linum*, Flax. See RADIOLA and LINUM.

LINOCIERA, a name given by Dr. Swartz, in honour of Geoffrey Linocier, a French phyſician, who flouriſhed at the cloſe of the ſixteenth and beginning of the ſeventeenth centuries. He publiſhed at Paris in 1584 an account of the officinal aromatics of the Eaſt and Weſt Indies. This book is accompanied by wooden cuts. Linocier alſo wrote upon the natural hiſtory of beaſts, birds, fiſhes, and ſerpents; but on theſe ſubjects he borrowed largely from Geſner and other authors. The preſent genus was adopted by Schreber, from Swartz, who firſt called it *Thouinia*, in his *Prodromus*. Dr. Smith however ſuggeſts that *Linociera* may probably not be a diſtinct genus from *Chionanthus*, merely becauſe they differ in the number of cells of the fruit: the former having two cells, the latter only one. But in ſome genera of this natural order, the number of cells in the ripe fruit has been diſcovered conſtantly to be fewer than in the young germen. In *Olea*, in particular, this was found to be regularly the caſe by the late M. Brouſſonet, though we know not that it had been before ſuſpected.—Swartz Ind. Occ. v. 1. 49. Schreb. 784. Willd. Sp. Pl. v. 1. 154. (Thouinia; Swartz Prod. 14.)—Claſs and order, *Diandria Monogynia*. Nat. Ord. *Sepiariæ*, Linn. *Jaſmineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, very ſmall, four-toothed, obtuſe, permanent. *Cor.* Petals four, equal, linear, channelled, erect, ſpreading at the top, conſiderably longer than the calyx. *Stam.* Filaments two, very ſhort and broadiſh; anthers linear, two-furrowed, the length of the corolla, erect, each adhering ſlightly to one ſide of two of the petals. *Piſt.* Germen ſuperior, ovate, quadrangular; ſtyle ſhort; ſtigma oblong, cloven. *Peric.* Berry, or rather Drupa, ovate, acuminate, of two cells. *Seeds* ſolitary, oblong.

Eſſ. Ch. Calyx four-toothed. Corolla of four petals, the two oppoſite ones connected at their baſe by the anthers. Fruit of two cells and two ſeeds.

L. *liguſtrina* is the only ſpecies deſcribed by Swartz. It is a native of dry open places in the Weſt Indies, eſpecially Jamaica and St. Domingo, flowering in June and July.

LINONASME, the name of a melancholy and ſolemn air of the ancient Greeks, on the death of Linus.

LINOS is ſuppoſed to imply the ſame air. Rouſſeau, however, calls it a kind of ruſtic ſong among the ancient Greeks; they had likewiſe a funeral ſong of the ſame name, which anſwered to what the Romans called Nænia. Some ſay that the Linos was invented in Egypt; while others aſcribe its invention to Linus, the Eubœan.

LINOSA, in *Geography*, a ſmall iſland in the Mediterranean, not far from the coaſt of Tunis, near the iſland of Lampedoſa.

LINOTA, in *Ornithology*. See LINNET, and FRINGILLA *Linota*.

LINOZOSTIS, in *Botany*, a name given by the ancient Greek writers to two plants very different from one another; the one is the *mercurialis*, or Engliſh mercury, a plant common in uncultivated places, and eaten by many boiled in manner of aſparagus; the other the *epilinum*, or dodder, growing upon the plants of flax.

Theophraſtus, Dioſcorides, and the ancient Greeks, uſe the word in the firſt ſenſe, and the modern Greeks in the latter.

The Latin authors call this *linozoſtis*, or *epilinum*, ſometimes *angina lini*; and *podagra lini*, looking on it as a diſeaſe which choaks the plant it grows on, and cauſes gouty tumours on the ſtalks. See DODDER.

LINQUES, in *Geography*, a country of Celebes, lying between the two ſtates of Binano and Bankale, not far from the bay of *Tourattea*; which ſee.

LINSCHOTTEN, a town of Holland; eight miles W. of Utrecht.

LINSDORF, a town of Bohemia, in the circle of Konigingratz; 32 miles E.S.E. of Geverſberg.

LINSE, a town of Pruſſia, in Oberland; 15 miles S.E. of Marienwerder.

LINSEED, or LINE-SEED, a ſort of grain, being the ſeeds of the common *flax*, (which ſee,) which enters the compoſition of ſeveral medicines, and yields, by expreſſion, an oil, that has moſt of the qualities of nut oil, and is according generally uſed, in lieu thereof, in painting, and for burning.

Thoſe who manufacture it in large quantities have mills turned by horſes or water, for the more expeditious diſpatch of their work. See OIL.

LINSEED, in the *Materia Medica*. Theſe ſeeds have an unctuous mucilaginous ſweetiſh taſte, without any remarkable ſmell. The oil which they yield in expreſſion, when carefully drawn without the application of heat, has no particular taſte or flavour: and in ſome properties differs conſiderably from moſt other oils of this kind; as congealing in water, not forming a ſolid ſoap with fixed alkaline ſalts, acting more powerfully as a menſtruum on ſulphurous bodies, than any other expreſſed oil that has been tried.

The ſeeds, boiled in water, yield a large proportion of a ſtrong flavourleſs mucilage; but to rectified ſpirit they give out little or nothing. Theſe ſeeds have been ſometimes uſed, in a ſeaſon of ſcarcity, inſtead of grain; but they appear to be an unwholeſome as well as an unpalatable food. They afford little nouriſhment, impair the ſtomach, and produce great flatulence, as Galen long ago obſerved. Tragus relates, that thoſe who fed upon them in Zealand, had the hypochondres in a ſhort time diſtended, and the face and other parts ſwelled; and that not a few died of theſe complaints.

Infuſions and decoctions of theſe ſeeds, like other vegetable mucilages, are uſed as emollients or demulcents in hoarſeneſſes, coughs, and pleuritic ſymptoms, which frequently prevail in catarrhal affections; they are alſo recommended in nephritic pains and ſtranguries; a ſpoonful of the ſeeds unbruiſed is ſaid, for theſe purpoſes, to be ſufficient for a quart of water. The ſeeds are alſo much uſed externally in emollient and maturating cataplaſms. The ſeeds from which the oil has been expreſſed, boiled in milk, and applied warm, on a cloth, to herniæ, are much recommended in in the Satyr. Sileſiac. Specim. 4. Obſ. 4. The expreſſed oil is an officinal preparation, and is ſaid to be of a more healing and balſamic nature than the other oils of this claſs; it has therefore been very generally employed in pulmonary complaints; alſo in colics, and conſtipations of the bowels. It is uſed in common with other oils as a vermifuge. Lewis Mat. Med. Woodv. Med. Bot.

Linseed *Cakes*, in *Agriculture*, the name of ſuch cakes as remain after the expreſſion of the oil from flax ſeed. They are at preſent much uſed in the fattening of cattle, ſheep, and other ſorts of live ſtock, and of courſe of great value and importance to the farmer. The price however has been of late ſo high as to greatly leſſen the demand for this article. See Oil-cake.

Linseed, *Infuſion of*. See Infusion.

LINSELLES, in *Geography*, a town of France, in the department of the North; five miles N. of Lille.

LINSENBAHRT, or as he is called in his works in Latin, Lentilius, Rosinus, in *Biography*, a phyſician, was born at Waldenburg, in the province of Hohenlohe, in February 1657. He commenced his ſtudies at Heidelberg at the age of fourteen, and thence removed to Jena in 1673. But his ſcanty means of ſubſiſtence compelled him the next year to engage as a teacher in the vicinity of Leipſic, where he continued till 1677. He then travelled, with a view to improve his ſituation, through ſeveral of the principal towns in the north of Germany, and ſettled at Mittau, in Courland, in the ſame capacity of teacher. To aid this feeble reſource, Linſenbahrt began likewiſe to practiſe medicine, in which his ſucceſs was ſuch, that the marquis of Anſpach appointed him phyſician to the town of Creilſheim, in Franconia; whither he repaired in 1680, after having been admitted a licentiate in medicine at Altdorf. He afterwards ſettled at Stutgard, and was patroniſed by the marquis of Dourlach; and, when that prince was driven by the war to take refuge at Baſle, he was nominated honorary phyſician to the duke of Wirtemberg, and became his firſt phyſician in 1711. He accompanied the ſon of this prince in his travels, during three years; and after his return, in 1716, remained in the tranquil exerciſe of his profeſſion until his death, in February 1733. Linſenbahrt was ardent in his attention to the qualities and operations of drugs during his whole life, regarding that ſpecies of knowledge as the moſt important to the phyſician, and being ſomewhat too negligent of the ſtudy of anatomy, and of the writings of the ancients. He was the firſt who recommended the uſe of arſenic internally, for the cure of intermittent fevers, in which its efficacy has been eſtabliſhed by recent obſervers, and eſpecially by Dr. Fowler, of York. He was a decided enemy to blood-letting, which he ſtrenuouſly endeavoured to diſcard from the practice of medicine; and particularly condemned the cuſtom, then prevalent among the Germans, of letting blood at the equinoctial periods, againſt which he publiſhed a treatiſe in his mother-tongue, at Ulm, in 1692. He was likewiſe author of the following works. "Tabula Conſultatoria Medica," Ulm, 1696. "Miſcellanea Medico-Practica tripartita," ibidem, 1694. "De Hydrophobiæ cauſâ et cura, Diſſertatio," ibid. 1770. "Eteodromus Medico-Practicus anni 1709," Stutgard, 1711. "Jatromnemata Theoretico-Practica," ibid. 1712. Eloy Dict. Hiſt. de la Med.

LINSPINS, or Linchpins, are ſmall pins of iron, which keep the wheel of a cannon, or waggon, on the axle-tree; for when the end of the axle-tree is put through the nave, the linſpin is put in to keep the wheel from falling off.

LINSTOCK, a ſhort ſtaff of wood, about three feet long, having at one end a piece of iron divided into two branches, each of which has a notch to hold a piece of match, and a ſcrew to faſten it there; the other end being alſo ſhod with iron, and pointed to ſtick into the ground, or in the deck when it is uſed at ſea. It is uſed by the gunners in firing-cannon. It is frequently uſed in ſmall veſſels, in an engagement, where there is commonly one fixed between every two guns, by which the match is always kept dry and ready for firing.

LINSTORP, in *Geography*, a town of Sweden, in the province of Medelpedia; 16 miles N. of Sundſwal.

LINT, in *Surgery*, is the ſcraping of fine linen, uſed by ſurgeons in dreſſing wounds. It is made into various forms, which acquire different names, according to the difference of their figures.

Lint made up in an oval, or orbicular form, is called a *pledgit*; if in a cylindrical form, or in the ſhape of a date olive-ſtone, it is called a *doſſil*.

Theſe different forms of lint are required for many purpoſes; as, 1. To ſtop blood in freſh wounds, by filling them up with dry lint before the application of a bandage; though if ſcraped lint be not at hand, a piece of fine linen may be torn into ſmall rags, and applied in the ſame manner. In very large hemorrhages the lint, or rags, ſhould be firſt dipt in ſome ſtyptic liquor, alcohol, or oil of turpentine, or ſprinkled with a ſtyptic powder. 2. To agglutinate and heal wounds; to which end lint is very ſerviceable, if ſpread with ſome digeſtive ointment, or balſam, or dipt in ſome vulnerary liquor. 3. In drying up wounds and ulcers, and forwarding the formation of a cicatrix. 4. In keeping the lips of wounds at a proper diſtance, that they may not haſtily unite, before the bottom is well digeſted and healed. 5. They are highly neceſſary to preſerve wounds from the injuries of the air. Small portions of lint tied round with thread are chiefly uſed in dreſſing wounds and ulcers of the deeper kind. They are always applied to the bottom of ſuch wounds, the remaining cavity being filled up with other portions of lint. By this means, the immediate removal of the dreſſings is not only provided for, but the poſſibility of leaving any part of them in the bottom of the wound is prevented.

In very large wounds, and eſpecially in amputations of the limbs, which operations are frequently required in the army and navy, at times when lint is very ſcarce, it will be very ſufficient to dreſs the bare bone and face of the wound with ſcraped lint, filling up the cavity with tow, and covering all with a large compreſs.

Surgeons of former ages formed compreſſes of ſponge, feathers, wool, or cotton, linen being ſcarce; but lint is far preferable to all theſe, and is at preſent univerſally uſed.

LIN-TCIN, in *Geography*, a city of China, of the ſecond rank, in Chan-tong, on the grand canal, much frequented by veſſels as a magazine for all ſorts of merchandize. N. lat. 36° 56′. E. long. 115° 31′.

LINTEL, in *Architecture*, the piece of timber which lies horizontally over door-poſts and window-jambs; as well to bear the thickneſs of the wall over it, as to bind the ſides of the walls together.

LINTELN, in *Geography*, a town of Germany, in the county of Verden; four miles N.E. of Verden.

LINTERNUM, or Liternum, in *Ancient Geography*. See Liternum.

LINTHAL, in *Geography*, a town of Switzerland, in the canton of Glaris; 12 miles S.W. of Glaris.

LIN-TIN, a town of China, of the ſecond rank, on a ſmall iſland in the province of Quang-tong; 15 miles N.E. of Macao.

LINTNER, in *Biography*, an excellent performer on the German flute at Berlin, in 1772, a diſciple of the late Frederic II. king of Pruſſia's flute-maſter, Quantz.

LINTON, in *Geography*, a ſmall market town in the hundred of Chilford, Cambridgeſhire, England, is ſituated ten miles from Cambridge, and forty-ſix from London. The town conſiſts of ſeveral irregular ſtreets, the chief of which is about half a mile in length; the houſes are principally low and covered with thatch; ſome however are of brick, and neatly built. The church is a ſpacious ſtructure, and built with flints, intermixed with ſtone and plaſter. It conſiſts of two aiſles, a nave, a chancel, and a large tower. It contains ſeveral monuments and ſepulchral memorials, among which is a handſome mural monument by Wilton, to the memory of Mrs. Elizabeth Bacon, and her brother Peter Sandley, eſq. A Sunday ſchool was recently eſtabliſhed in this town by the exertions of the Rev. Mr. Fiſher, the vicar; it now affords tuition to upwards of an hundred children. A market, principally for corn, is held on Thurſdays; it was originally on Tueſdays, and was granted in the year 1245, with an annual fair for three days. The fair has been diſcontinued, but two others have been eſtabliſhed; one for ſheep, and one principally for hiring harveſt men. In the reign of Edward III. there was an alien priory at Linton, ſubordinate to the abbey of St. Jacutus de Inſula in Brittany; being ſeized for the king in the reign of Henry V., it was given by his ſucceſſor to the maſter and fellows of Pembroke hall, Cambridge. At Barham alſo, in this pariſh, was a priory of Crutched Friars, ſo early as the year 1292; the ſcite was granted by Henry VIII. to Philip Pariſh, eſq. and afterwards to John Millecent, eſq. who was before poſſeſſed of the manor. In the Millecents the priory and manor continued till the year 1740, when John Millicent, eſq. the laſt of the family, died; his widow, afterwards married to the Rev. C. Lonſdale, left her eſtates to the maſter and fellows of Pembroke hall. Barham hall, Mrs. Lonſdale's ſeat, appears to have been formed out of the conventual buildings: the hall, chapel, and cloiſters, ſtill remain: it was appropriated, by Mrs. Lonſdale's will, as a country ſeat for the maſter of Pembroke hall for the time being. In the population return to parliament in the year 1801, the pariſh of Linton was ſtated to contain 183 houſes, and 1157 inhabitants. Lyſons' Magna Britannia, vol. ii. Beauties of England and Wales, vol. ii.

LINTZ, a town and citadel of Germany, ſurrounded with an old wall, and ſituated on the E. ſide of the Rhine, containing about 600 houſes; 10 miles S.S.E. of Bonn. N. lat. 50° 34'. E. long. 7° 14'.—Alſo, a well-built and populous town of Auſtria, ſeated on the Danube; conſiſting of a ſingle ſtreet, with ſome annexed ſuburbs, in which is the ſovereign's citadel, ſituated on an eminence, commanding a fine proſpect. The trade of the town is conſiderable, and it has fairs that poſſeſs privileges under proper regulations, at Eaſter and St. Bartholomew's; 30 miles S.E. of Paſſau. N. lat. 48° 18'. E. long. 14° 15'.

LINTZENEGG, a town of Auſtria; 10 miles S. of Zwetl.

LINUFAR, in *Botany*, a name uſed by ſome of the writers of the middle ages, to expreſs the water-lily. The Arabians gave this genus of plants the name of *nilufar*, and this word *linufar* is only formed of that, by tranſpoſing ſome of the letters.

LINUM, in *Botany*, the λινον of Dioſcorides, Theophraſtus, and other ancient Greek authors, appears to be derived from λινεω, *to hold*, the fibres of this plant being ſo remarkable for their tenacity, that its herbage has always been in the greateſt eſtimation for the manufacture of linen cloth, whilſt its ſeeds by preſſure afford a valuable oil. (See FLAX.)—Linn. Gen. 153. Schreb. 206. Willd. Sp. Pl. v. 1. 1533. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 342. Prod. Fl. Græc. v. 1. 214. Ait. Hort. Kew. ed. 2. v. 2. 184. Tournef. t. 176. Juſſ. 303. Lamarck Illuſtr. t. 219. Gærtn. t. 112.—Claſs and order, *Pentandria Pentagynia*. Nat. Ord. *Gruinales*, Linn. *Caryophyllaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five leaves, lanceolate, erect, ſmall, permanent. *Cor.* funnel-ſhaped; petals five, oblong, gradually broader towards the upper part, obtuſe, much ſpreading, large. *Stam.* Filaments five, awl-ſhaped, erect, the length of the calyx; (alſo five rudiments alternating with them) anthers ſimple, arrow-ſhaped. *Piſt.* Germen ſuperior, ovate; ſtyles five, thread-ſhaped, erect, as long as the ſtamens; ſtigmas ſimple, reflexed. *Peric.* Capſule globoſe, bluntly five-ſided, of ten cells and ten valves. *Seeds* ſolitary, ovate or flattiſh, acuminated, ſmooth.

Eſſ. Ch. Calyx five-leaved. Petals five. Capſule ſuperior, with ten valves and ten cells. Seeds ſolitary.

In the 14th edition of Linnæus's *Syſtema Vegetabilium* we meet with twenty-two ſpecies of *Linum*. Willdenow has twenty-nine, beſides which, four, not mentioned by him, occur in the *Hortus Kewenſis*, and one in the *Prodromus Floræ Græcæ*. But from the liſt is to be deducted *L. Radiola*, which is the *Radiola millegrana* of Dr. Smith's *Flora Britannica*, 202.—The genus is divided into two ſections, the firſt having alternate, the ſecond oppoſite, leaves.—Examples of the firſt ſection are

L. *uſitatiſſimum*. Common Flax. Linn. Sp. Pl. 397. Engl. Bot. t. 1357. Curt. Lond. faſc. 5. t. 22.—Calyx-leaves ovate, acute, three-nerved. Petals crenate. Leaves lanceolate, alternate. Stem moſtly ſolitary.—Not unfrequent in fields throughout the more temperate parts of Europe, in conſequence probably of its being a plant of ſuch general cultivation, flowering in July. *Root* annual, fibrous, ſmall. *Stem* erect, round, ſmooth, leafy. *Leaves* entire, three-nerved, ſmooth. *Flowers* on ſtalks, erect, of a ſky-blue colour. *Seeds* elliptical, very ſhining. For the uſes and management of this valuable plant, we need not repeat what is already given under the article FLAX.

L. *trigynum*. Three-ſtyled golden Flax. Sm. Exot. Bot. t. 17. Ait. Hort. Kew. ed. 2. n. 3. Curt. Mag. t. 1100.—Leaves alternate, elliptical, ſerrated, acute. Styles three. Capſule of ſix cells.—A native of the Eaſt Indies, where it was gathered by colonel Hardwicke on the ſides of mountains flowering in December. The natives call it *Gul Aſhorfee*, from its fine golden hue, *Gul* ſignifying a flower, and *Aſhorfee* a coin of the ſame metal current in India, of the value of 2*l.* ſterling.—*Stem* ſhrubby. *Branches* round and leafy. *Leaves* ſmooth, dark green, pointed, on a ſhort footſtalk. *Flowers* large and handſome, nearly inodorous.

L. *hirſutum*. Hairy Flax. Linn. Sp. Pl. 398. Willd. n. 4. Jacq. Auſtr. t. 31.—Calyx hirſute, acuminate. Flowers ſeſſile, alternate. Leaves on the branches oppoſite.—A native of Auſtria and Hungary, flowering in June and July.—*Root* perennial, woody. *Stems* from a foot and a half to two feet in height, branching towards the top. *Leaves* lanceolate or ovate, hairy at their edges and on their backs, ſometimes nearly ſmooth. *Flowers* blue; the petals ſo cloſely united at the baſe as to reſemble a monopetalous, funnel-ſhaped flower. Linnæus remarks that this is very cloſely allied to *L. nodiflorum*.

L. *hypericifolium*. Mallow-flowered Flax. Curt. Mag. t. 1048,

t. 1048, approaches very nearly to *L. hirſutum.* Its flowers however are larger, and of a reddiſh or purpliſh tinge.

L. *arboreum.* Tree Flax. Linn. Sp. Pl. 400. Curt. Mag. t. 234.—Leaves wedge-ſhaped. Stems arboreſcent. —A native of the Levant, from whence it was ſent to England by Dr. Sibthorp in the year 1788. It flowers from May to Auguſt. This beautiful ſpecies is an arboreous ſhrub, riſing to the height of ſeveral feet. *Stems* rather ſlender, leafy. *Leaves* on ſhort footſtalks, the upper ones ſlightly embracing the ſtem, of a glaucous colour.

The two following ſpecies come under the other ſection of this genus, from having oppoſite leaves.

L. *catharticum.* Purging Flax. Mill-mountain. Linn. Sp. Pl. 401. Engl. Bot. t. 382. Curt. Lond. faſc. 3. t. 19. Fl. Dan. t. 851.—Leaves oppoſite, obovato-lanceolate. Stem forked. Petals pointed.—Not uncommon in elevated, dry paſtures in all parts of Great Britain, bearing flowers from June to Auguſt.—*Root* annual, ſmall. *Stems* leafy, erect, many-flowered. *Leaves* obtuſe, entire. *Flowers* ſmall, white, pendulous before they expand.—Dr. Smith obſerves, in the *Flora Britannica,* that *L. catharticum* is very nearly allied to *Geranium,* for that its ſtamens are ſometimes monadelphous. The whole herb is ſmooth, bitter, and has long been celebrated for its purgative qualities.

L. *quadrifolium.* Four-leaved Flax. Linn. Sp. Pl. 402. Curt. Mag. t. 431.—Leaves four in a whorl.—A native of the Cape of Good Hope, flowering in May and June. *Root* thick and woody. *Stems* numerous, about ſix inches in height, forked, ſlender, upright. *Leaves* four in a whorl. *Flowers* yellow.

This is the original *quadrifolium* of Linnæus, that of Ray having blue flowers.

LINUM, in *Gardening,* comprehends plants of the herbaceous, annual, and perennial ſhrubby kinds, of which the ſpecies are the common flax (L. uſitatiſſimum); the perennial flax (L. perenne); the ſhrubby flax (L. ſuffruticoſum); the tree flax (L. arboreum); and the African flax (L. Africanum.)

In the ſecond ſort there is a variety which is procumbent, with ſmaller flowers.

Method of Culture.—All theſe plants may be increaſed by ſeeds, layers, and cuttings.

But the two firſt ſorts are beſt raiſed by ſowing the ſeeds in the early ſpring months, as March, or the following month, the former in fields or plantation-grounds, where the ſoil is freſh, good, and well reduced into order, by frequent digging over, or ploughing and harrowing, in narrow drills, or broadcaſt, and raked or harrowed in with a light harrow; the plants being afterwards kept perfectly clean from weeds by repeated hoeings.

About the end of Auguſt, when the plants have attained their full growth, and begin to turn yellow at bottom, and brown at top, and their ſeeds to ripen, it is proper time to pull them; though, if it were not for the ſake of the ſeed, they might be pulled a little before the ſeeds ripen, by which the flax is generally better coloured and finer; but if ſuffered to ſtand till the ſeeds are fully ripe, it is commonly ſtronger, ſomewhat coarſer, and more in quantity. It ſhould be pulled up by handfuls, roots and all, ſhaking off all the mould; then either ſpreading them on the ground by handfuls, or binding them in ſmall bunches, and ſetting them upright againſt one another, for ten days or a fortnight, till they are perfectly dry, and the ſeed fully hardened, then houſed, and the ſeed thraſhed out, cleaned, and placed in a dry airy ſituation, being afterwards put up for uſe. The flax, after being rippled and ſorted, ſhould be carried to a pond of nearly ſtagnant water, being placed in it with the bundles croſſing each other in different directions, ſo as to keep the whole in a cloſe compact ſtate, being kept juſt below the ſurface of the water, by proper weights applied upon it. It ſhould remain in this ſteep till the ſtems become brittle and the bark readily ſeparates, when it muſt be taken out and ſpread thinly on a ſhort paſture, being occaſionally turned until it becomes perfectly bleached and dry, when it is in a proper ſtate for the purpoſe of being converted into flax by the huckler.

With regard to the latter, or perennial ſort, it ſhould be ſown in a bed or border of good earth, in ſhallow drills at the diſtance of ſix inches; and when the plants are two or three inches in height, they ſhould be thinned to the ſame diſtances, and in autumn be planted out in the places where they are to grow. But it is probably a better practice to ſow them at once in the places where they are to grow, thinning them out properly afterwards.

The three other ſorts may be beſt increaſed by planting cuttings of the branches in pots of light freſh earth, plunging them in the tan hot-bed, or by layers laid down in the later ſummer months. When the plants in either mode have ſtricken good root, they may be removed into ſeparate pots, and be managed as other tender exotic plants, that require the protection of the green-houſe. And they may likewiſe be raiſed from ſeeds when they can be procured, which ſhould be ſown in pots, and placed in a hot-bed in the ſpring ſeaſon.

The firſt ſort may be ſaid to be one of the moſt valuable plants in the whole vegetable kingdom; as from the bark of its ſtalks is manufactured flax or lint, for making all ſorts of linen cloth; from the cloth, when worn to rags, is made paper; and from the ſeeds of the plant linſeed oil is expreſſed, which is much uſed by painters, and in other arts; and the refuſe, after expreſſion, forms the oil-cakes ſo valuable in the fattening of cattle, ſheep, and other ſorts of live ſtock.

A few plants of this, and the ſecond ſort, may be introduced in the clumps and borders of the pleaſure-ground; and the three other ſorts afford variety in green-houſe collections among other potted plants.

LINUM *Carpaſium, Carpaſian flax,* or *linen,* a term often occurring in the old writers, and uſed by different authors in very different ſenſes.

The firſt uſe we find made of the word, is for the expreſſing a kind of flax which was finer and ſmaller, as well as brighter and more gloſſy, than any other. Pliny uſes the word in this ſenſe, and tells us, that ſuch flax was principally brought from Spain; and that both it, and the linen made of it, were, in his time, called by the name *carpaſian:* from this it became a cuſtom to call all very fine flax, or fine linen, carpaſian linen, and the word ſignified no more than delicate, or fine.

The modern Greeks uſe the word in this ſenſe, and Suidas expreſſes the fineſt linen veils by the term *carpaſian.* The author of the Periplus Maris Erythræi, who was contemporary with Pliny, calls the flax, of which the Indian linens were made, *carpaſos;* but none of the older Greeks have the word. This author is not, however, to be appealed to for aſcertaining the purity of the language of the ancients; for it is plain that he has taken in many words which are not good Greek, nor ever were uſed by any author of credit, but are the mere technical terms of the tradeſmen and merchants of that time.

Pauſanias uſes the word carpaſium linum in a very different ſenſe from all theſe; for with him it is made to expreſs the flax made of the ſtone aſbeſtos, and the linen made of this, which was thrown into the fire to be cleaned. Solinus uſes the word alſo in the ſame ſenſe: he ſays, that in Caryſtos there was found that kind of flax which remained unhurt in the fire; and Hieronymus Mercurialis thinks that the *carbaſus* of the ancient Romans was a word properly uſed only to ſignify the carpaſian flax of Pauſanias, which was not to be deſtroyed by the fire, and was the true ***linum incombuſtibile***, or threads of the aſbeſtos ſtone, or linen made of that material. This, however, is not the ſenſe of the word in later times, for we find it evidently uſed for all linen manufactures of whatever kind.

Linum, *Caryſtium*, in *Natural Hiſtory*, a name given by Pauſanias to the aſbeſtos. It was found plentifully in this author's time, near Caryſtos, a town in the Negropont, and thence obtained its name.

Linum *Catharticum*, *Purging flax*, in *Medicine*, makes a common purge among the country people. It is almoſt as rough as that of *gratiola*.

It is a ſpecies of wild flax, diſtinguiſhed by the name of meadow flax, with ſmall flowers which appear in July, and commonly called mountain-flax, growing without culture on chalky hills and dry paſture grounds in many parts of England, and is taken in infuſion in ale.

This herb is ſaid to be an effectual and ſafe cathartic; an infuſion of a handful of the freſh leaves in whey or white wine, or a drachm of the leaves in ſubſtance with a little cream of tartar and aniſeeds, is directed for a doſe. Linnæus recommends an infuſion of two drachms of the dry leaves as a mild laxative.

It is greatly recommended by ſome in dropſies, and to prevent its griping they mix aniſe or ſome other of the carminative ſeeds with it. It is given in moſt chronic caſes, where people's conſtitutions are ſtrong enough to bear it, and often with great ſucceſs.

Linum *Vivum*, or *incombuſtibile*, cloth made of a foſſile, ſtony ſubſtance, of a whitiſh colour, and woolly texture, ſeparable into threads, or filaments, which will endure the fire without conſuming. See Amianthus and Asbestus.

As to the art of managing this mineral, and of ſpinning and weaving it, &c. the accounts we have are various.

Marco Polo, the Venetian, gives us the manufacture of the linum, found in the province of Chinchinthelas, in Tartary, from one Curſica, a Turk, ſuperintendant of the mines of that country, as follows. The lanuginous mineral, being firſt dried in the ſun, is then pounded in a braſs mortar, and the earthy part ſeparated from the woolly, which is afterwards well ſeparated from filth; being thus purged, it is ſpun into thread, like other wool, and afterwards woven into cloth, which, if foul or ſpotted, they cleanſe, he ſays, by throwing it into the fire for an hour's time, whence it comes out unhurt, as white as ſnow: which very method, according to the account given us by Strabo, ſeems to have been uſed, in ordering the Cretan amianthus; with this addition, that after it was pounded, and the earthy part ſeparated from the woolly, he ſays it was combed; and ſo does Agricola.

Signior Ciampani, after deſcribing four ſorts of the linum, whereof he had ſpecimens in his muſeum; the firſt ſent him from Corfu, the ſecond from Seſtri di Ponente, the third coarſer and darker than the reſt, and the fourth from the Pyreneans; and after obſerving, that though he kept it three weeks in a glaſs-houſe fire, yet he found it unaltered, though it could not preſerve a ſtick wrapped in it, from the fire; he proceeds to ſhew the manner of ſpinning, and making it into cloth, which he effected thus:—He firſt laid the ſtone in water, if warm the better, for ſome time to ſoak; then opened and divided it with his hands, that the earthy parts might fall out of it, which are whitiſh like chalk, and ſerve to bind the thready parts together. This makes the water thick and milky. That operation he repeated ſix or ſeven times, with freſh water, opening and ſqueezing it again and again, till all the heterogeneous parts were waſhed out, and then the flax-like parts were collected, and laid in a ſieve to dry. As to the ſpinning, he firſt ſhews a method diſcovered to him, which is thus:—Lay the linum, cleanſed as before, between two cards, ſuch as they card wool with, where let it be gently carded, and then clapped in between the cards, ſo that ſome of it may hang out of the ſides; then lay the cards faſt on a table, or bench; take a ſmall reel, made with a little hook at the end, and a part to turn it by, ſo that it may be eaſily turned round; this reel muſt be wound over with white thread; then, having a ſmall veſſel of oil ready, with which the fore finger and thumb are conſtantly to be kept wet, both to preſerve the ſkin from the corroſive quality of the ſtone, and to render the filaments thereof more ſoft and pliant, by continuing to twiſt about the thread on the reel in the aſbeſtos hanging out of the cards, ſome of the latter will be worked up together in it; and, by little and little, the thread may, with care, be woven into a coarſe ſort of cloth; and, by putting it into the fire, the thread and oil will be burnt away, and the incombuſtible cloth remain.

But finding this way, of uniting the ſtone with the thread, very tedious; inſtead of the thread, he put ſome flax on a diſtaff, and, by taking three or four filaments of the aſbeſtos, and mixing them with the flax, he found they might be eaſily twiſted together, and the thread thus made much more durable and ſtrong; ſo that there is no need of carding, which rather breaks the filaments, than does any good: only open and ſeparate the filaments, after waſhing, on a table, and take them up with the flax, which is ſufficient.

As to the making of paper, he ſays, in the waſhing of the ſtone there will remain ſeveral ſhort pieces in the bottom of the water, of which paper may be made in the common method. He concludes with the beſt way of preſerving the cloth, or any thing made of the linen, which, by reaſon of its exceſſive dryneſs, is very apt to break, and twiſt; and it conſiſts in keeping it always well oiled, which is the only preſervative. When the cloth is put in the fire, the oil burns off, and the cloth comes out white and purified.

Linum, in *Ancient Geography*, a country of Aſia Minor, in the province of Helleſpont, between Parium and Priape.—Alſo, a promontory of Illyria, in Chaonia.

LINUS, in *Biography*, ſuppoſed to be the firſt biſhop of Rome, was born at Volterra, in Tuſcany. According to Irenæus he received his biſhopric from the hands of the apoſtles Peter and Paul, which he is ſuppoſed to have retained twelve years. He is mentioned by St. Paul in the ſecond epiſtle of Timothy, and is ſaid, by ſome writers, to have been the ſon of Claudia, who is mentioned at the ſame time. Nothing more is known of him which can be relied on, though it has been ſaid that he teſtified to the truth of his principles by ſuffering martyrdom; and two letters in the ſecond volume of the Biblioth. Patr. have been aſcribed to him, but there is no good authority for theſe facts. See Lardner, vol. ii. edit. 1788.

Linus. This perſonage and Orpheus ſeem to have been the moſt ancient poets and muſicians of Greece; but to determine whether Linus was the maſter of Orpheus, or Orpheus of Linus, would be as vain to attempt, as difficult to accompliſh. All that can be done at this diſtance of time, is to compare the opinions of ancient writers upon the ſubject, and to incline to the moſt numerous and reſpectable evidence: and in purſuing this method, it appears that the majority are in favour of the ſuperior antiquity of Linus. No teſtimony places him in a more remote period, or does more honour to his memory, than that of Herodotus; who tells us (Euterp.) "that among other memorable cuſtoms, the Egyptians ſing the ſong of Linus, like that which is ſung by the Phœnicians, Cyprians, and other nations, who vary the name according to the different languages they ſpeak. But the perſon they honour in this ſong, is evidently the ſame that the Grecians celebrate: and as I confeſs my ſurprize at many things I found among the Egyptians, ſo I more particularly wonder whence they had this knowledge of Linus, becauſe they ſeem to have celebrated him from time immemorial. The Egyptians call him by the name of *Maneros*, and ſay he was the only ſon of the firſt of their kings, but dying an untimely death, in the flower of his age, he is lamented by the Egyptians in this mourning ſong, which is the only compoſition of the kind uſed in Egypt."

According to archbiſhop Uſher, Linus flouriſhed about 1280 years before Chriſt, and he is mentioned by Euſebius (Præp. Evang.) among the poets who wrote before the time of Moſes. Diodorus Siculus, who is very diffuſe in his account of Linus (lib. iii. cap. 85.) tells us from Dionyſius of Mitylene the hiſtorian, who was contemporary with Cicero, that Linus was the firſt among the Greeks who invented verſe and muſic, as Cadmus firſt taught them the uſe of letters. The ſame writer likewiſe attributes to him an account of the exploits of the firſt Bacchus, and a treatiſe upon Greek mythology, written in Pelaſgian characters, which were alſo thoſe uſed by Orpheus, and by Pronapides, the preceptor of Homer. Diodorus ſays, likewiſe, that he added the ſtring lichanos to the Mercurian lyre, and gives to him the invention of rhythm and melody, which Suidas, who regards him as the moſt ancient of lyric poets, confirms. He is ſaid by many ancient writers to have had ſeveral diſciples of great renown, among whom were Hercules, Thamyris, and, according to ſome, Orpheus.

Hercules, ſays Diodorus, in learning of Linus to play upon the lyre, being extremely dull and obſtinate, provoked his maſter to ſtrike him, which ſo enraged the young hero, that inſtantly ſeizing the lyre of the muſician, he beat out his brains with his own inſtrument. Heroes are generally impatient of controul, and not often gifted with a taſte for refined pleaſures; hence, relying merely on corporal force, their mental faculties, feeble perhaps by nature, are ſeldom fortified by education.

With reſpect to the dirges, which Plutarch, from Heraclides of Pontus, mentions as written by Linus, we find no account of them in any other ancient author. It appears, however, that his death has given birth to many ſongs of that kind, which have been compoſed in honour of his memory. A feſtival was likewiſe inſtituted by the name of *Linia*, for the celebration of his virtues; and ſo numerous were his inventions, and various the periods and places in which different authors fix them, that ſome have tried to reconcile theſe jarring accounts, by ſuppoſing that there were three ſeveral illuſtrious perſonages of that name; a ſuppoſition which we ſhall not pretend either to affirm or deny.

"The Thebans, ſays Pauſanias (in Bæotic,) aſſure us, that Linus was buried in their city; and that Philip, the ſon of Amyntas, after the battle of Cheronæa, which was fatal to the Greeks, excited by a dream, removed his bones into Macedon, whence, by counſel received in another dream, he ſent them back to Thebes; but time has ſo defaced his tomb, that it is no longer diſcoverable."

Homer (lib. xviii. ver. 569.) has paid a tribute to the memory of Linus, in his deſcription of the ſhield of Achilles.

"To theſe a youth awakes the warbling ſtrings,
Whoſe tender lay the fate of Linus ſings;
In meaſur'd dance behind him move the train,
Tune ſoft the voice, and anſwer to the ſtrain."

Pope, in his note on this paſſage, ſays, from Pauſanias, that "before the yearly ſacrifice to the muſes on mount Helicon, the obſequies of Linus were performed, who had a ſtatue and altar erected to him in that place. Homer alludes to that cuſtom in this paſſage, and was doubtles fond of paying this reſpect to the old father of poetry."

LIO, in *Geography*, a lake of Thibet, about 30 miles in circumference. N. lat. 31° 22′. E. long. 86° 34′.

LIOI-KIA-LANC-TSA, a town of Thibet, 100 miles S.S.E. of Laſſa. N. lat. 28° 8′. E. long. 92° 44′.

LIOIPOU, a lake of Thibet, about 30 miles in circumference. N. lat. 34° 27′. E. long. 90° 34.

LION, Leo, in the Linnæan ſyſtem of *Zoology*, is a ſpecies of quadrupeds belonging to the *felis* or cat kind, with a long tail and pale-red or tawny body. See Felis.

The lion is an inhabitant of all parts of Africa, and the hot parts of Aſia, ſuch as India and Perſia, and ſome few are found in the deſarts between Bagdat and Baſſorah, on the banks of the Euphrates; but they moſt abound in the torrid zone, where the ſize is the largeſt, and their rage moſt tremendous, being inflamed by the influence of a burning ſun and a very dry ſoil. It is obſerved, that, though they reign abſolute maſters over every beaſt, their rage diminiſhes and their timidity increaſes as they approach the habitation of the human race. They have been alſo known to ſpare the weaker animals, and many inſtances are related by A. Gellius, Ælian, and Pliny, &c. of their gratitude. Lions are capable of being tamed; and the monarch of Perſia is ſaid, on days of audience, to have two large lions chained on each ſide of the paſſage to the room of ſtate, led there by keepers in chains of gold. The lion preys on all kinds of animals; having rouſed them into view by his roar, he ſtarts on his prey, ſtriking it with his talons, and tearing it to pieces. He alſo invades the folds, leaping over the fences with his prey, and his ſtrength is ſo great, that he can carry off a middling ox with the utmoſt eaſe. He ſometimes ſeizes his prey by ſurprize, and mankind falls a victim to his hunger, more through neceſſity, as it is ſaid, than choice. The Arabs have a notion of his ſparing the tender ſex, but Dr. Shaw informs us in his Travels, p. 244, that the lion obſerves no diſtinction in theſe days. The fleſh is often eaten in Barbary, and is ſaid to reſemble veal in taſte. Pennant's Brit. Zool. p. 165, &c.

Lion-*Monkey*. See Simia *Oedipus*.

Lion, *Seal*. See Phoca *Leonina*.

Lion-*Puceron*, in *Natural Hiſtory*, the name given by Mr. Reaumur to a genus of worms which deſtroy the pucerons in the ſame manner that the formica leo does the *ants*.

Theſe little inſects are a prey alſo to a ſort of worm hatched from the egg of a two-winged fly. This has no legs, and is of ſeveral colours. See Ver-*Puceron*.

Though theſe lion-pucerons be all hexapodes, yet they are of different origin; ſome being produced from the eggs of a four-winged fly, others from thoſe of a beetle. As the formica leo has two horns, the extremities of which ſerve him by way of mouths, our lion-puceron has the ſame kind alſo; but as the former of theſe inſects can only move backwards, and is forced to make ſnares for his prey, not being able to hunt it, this creature runs very nimbly in the com-

-mon way, and ſeizes its prey, without having recourſe to ſuch ſtratagems.

The body of the lion-puceron is longer than that of the formica leo, and is flat; the breaſt is the thickeſt and broadeſt part of it, and from this it gradually tapers off to a point at the tail; it has two legs fixed to the breaſt, the other four to the anterior rings of the body; and when it moves, the poſterior end of the body ſerves it in the place of a ſeventh leg, for it always bends it downward, and draws it along the ſurface it walks upon. The back of this creature is not ſmooth or gloſſy, but is every where rough, and full of wrinkles, and ſeems as if every ring of it was compoſed of ſeveral other ſmaller rings.

This is the general deſcription of the creature, treating of it in the general way, theſe characters ſuiting all the kinds of it. There are others, however, by which the whole claſs may be divided into three principal kinds.

Theſe are much more voracious devourers of the pucerons, than the worms which feed on them. A ſmall puceron, ſeized by one of them, is eaten in an inſtant, and the very largeſt is not the work of half a minute for them.

Theſe creatures are very ſmall when firſt produced from the egg, and yet they immediately begin to feed. They are ſo ravenous of food alſo, that whenever they can they catch and eat one another. But as the pucerons, among which they live, are eaſier to be caught, they uſually eſcape one another's fury pretty well; unleſs where there is a ſcarcity of the pucerons, or when they offend one another.

It is eaſy to conceive that a creature, which feeds ſo very faſt, muſt ſoon arrive at its full growth; and this is the caſe with theſe animals, for within five or ſix days of their being hatched from the egg, they are ready for their final tranſformation, or the putting on the form of the animals to whoſe eggs they owed their origin. In order to this, the creature leaves the place where he has hitherto fed, and ſeeks the folds of a leaf, or ſome other ſuch convenient receptacle, where it ſpins a web of very fine ſilk, every way ſurrounding its body with it, and under this cover paſſes the ſtate of a nymph or chryſalis. The ſilk of this web is not only very ſtrong, but the threads are very cloſely laid together, ſo that it is much firmer than the webs of any of the caterpillar kind. It is of a roundiſh figure, and is ſomewhat ſmaller than a pea.

This round figure is owing to the form into which they roll up their body, which ſerves as a mould for it; and the orifice, out of which the ſilky matter is produced, is at the extremity of the poſterior part of the body. The creature continues in this ſtate about three weeks, if it be in the beginning of ſummer that it goes into it; but if toward autumn, it remains in it all the following winter; and is afterwards, in ſpring, ſeen to come out in the form of a very beautiful fly, of a remarkable large ſize, in proportion to the creature it is produced from, and the web out of which it comes. It is a very long-bodied one, and much reſembles the libella or dragon-fly, only that its wings are larger in proportion to its body: theſe wings are of a moſt delicately fine ſtructure, the fineſt gawſe being coarſe and thick in compariſon to them. Theſe, when the creature is at reſt, are placed in an angle over the body, and form a ſort of canopy or tent for it; but they are ſo perfectly tranſparent, that the body is eaſily ſeen through them. The body and breaſt are all green, and that of a very beautiful tinge; but the moſt remarkable beauty of this creature is its eyes: theſe are large and prominent, and are of a fine gold colour, and of greater luſtre than the moſt highly poliſhed metal.

The eggs of this fly are a very ſingular object, and cannot have eſcaped the eye of any perſon who is converſant among the inſects which live on trees; though of the many who have ſeen them, perhaps few or none ever found what they really were. It is common to ſee on the leaves and pedicles of the leaves of the plum-tree, and ſeveral other trees, as alſo on their young branches, a number of long and ſlender filaments, running out to about an inch in length, and being of the thickneſs of a hair: ten or twelve of theſe are uſually ſeen placed near one another, and a vaſt number of theſe cluſters are often found on the ſame tree. The end of each of theſe filaments is terminated by a ſort of ſwelling or tubercle of the ſhape of an egg. People who have obſerved theſe, have generally ſuppoſed them to be of vegetable origin, and that they were a ſort of paraſitical plants, growing out of others, as the miſletoe, moſſes, &c. from the oak and other trees. They very much reſemble in figure thoſe ſpecies of mouldineſs, which Malpighi and others have figured under the ſhape of little muſhrooms, only they are much larger than thoſe little plants, and bear the heat of the ſun and other accidents uninjured, which would deſtroy the tender plants of that kind. There is a time, when theſe egg-like balls, which terminate every one of theſe filaments, are found open at their ends, and in this ſtate they very much reſemble flowers, and they are in this ſtate figured by ſome authors under the name of flowers of a ſingular kind, found on the leaves of the willow. All this, however, is wholly erroneous, and the purſuing the hiſtory of our lion-pucerons ſhews their true origin to be from the fly of that creature. What theſe authors took for flowers of the willow were only the eggs of this fly, out of which the young animals had been hatched, and had made their eſcape. The leaves and branches, on which theſe eggs are found, are uſually ſeen covered over with the pucerons; and the creature providing a place where her young ſhall find nouriſhment as ſoon as hatched, places her eggs in the midſt of theſe harmleſs and defenceleſs animals, fixing each on a ſlender pedicle, yet ſufficiently ſtrong to bear its weight. If theſe eggs be nicely examined, a worm may be diſcovered in them while yet whole; but the moſt certain way of judging of them is, to put ſeveral of them into a box, in which caſe every one of them is found at a proper time to hatch, and to give an inſect; which, when viewed by the microſcope, appears plainly to be a lion-puceron in all its parts, and requiring only increaſe in ſize, without any change of ſhape, to be one of thoſe we have already deſcribed, as feeding ſo voraciouſly on the pucerons. Reaumur's Hiſt. Inſ. vol. vi. p. 142.

LION, *Ant*, in *Zoology*. See FORMICA *Leo*.

LION'S *Foot, Candia*, in *Botany*. See CATANANCHE.

LION'S *Leaf*. See LEONTICE.

LION'S *Tail*. See LEONURUS.

LION'S *Cove*, in *Geography*, a ſmall bay in the ſtraits of Magellan, ſurrounded by rocks. The water is deep, the ground is good, and water may be obtained, but no wood. The only refreſhments which this bay affords are limpets, muſcles, rock fiſh, and celery. S. lat. 53° 26. W. long. 74° 25′.

LION *Mountain*, a mountain of Africa, near the Cape of Good Hope, deriving its name from a ſuppoſed reſemblance to the lion. It conſiſts of the Lion's head, which is a bare rock 2160 feet high; and the Lion's tail or rump, which is alſo rocky, but covered with a ſlight ſtratum of earth, 1143 feet high. This earth yields an inferior kind of graſs, to which every one's cattle has acceſs. Upon both theſe ſummits are erected enſign ſtaffs, upon which ſignal flags are hoiſted as ſoon as any ſhips are perceived at ſea. Theſe ſignals, whilſt the Cape remained in poſſeſſion of the Dutch, were changed every month; and advices were ſent two years before to Holland and the India ſettlements; and ſealed letters, containing the detail of them, are given to the commanders of veſſels, who are to touch at the Cape; which letters are opened when they arrive within ſight of the mountains, that they may aſcertain whether or not the place be in the hands of their countrymen, and accordingly avoid it or proceed to an anchorage in the bay. A cannon is alſo fired on Lion's head, ſo often as to correſpond to the number of ſhips that appear, in order to give notice to Cape Town; and this notice is facilitated by the reverberation which the ſound makes againſt the ſteep ſides of the Table mountain.

Lion *d'Angers*, *Le*, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the diſtrict of Segré; 10 miles N.N.W. of Angers. The place contains 1728, and the canton 9578 inhabitants, on a territory of 247½ kiliometres, in 12 communes.

LIONARDO da Vinci, in *Biography*. See *Da* Vinci.

LIONCELES, in *Heraldry*, a term for lions when there are more than two of them borne in any coat of arms, and no ordinary between them.

LIONINE, or Lionade, in the hiſtory of the *Coins* current in Ireland, a name given to certain coins, imported privately from France and other places. There were, beſide theſe, many others of the ſame ſort, impreſſed with eagles, roſes, and the like, and called by names ſignifying thoſe impreſſions. They were a very baſe and poor ſort of money; the penny *lionade*, or *lionine*, not coming up to the value of the halfpenny of the coin of the kingdom. They were diſcountenanced in the year 1300; and good money being ſtruck there, it was made death, and confiſcation of goods, to import any of them, and the run of them was thus ſtopped.

LIONS, in *Geography*, a town of France, in the department of the Eure, and chief place of a canton, in the diſtrict of Les Andelys; nine miles N. of Grand Andelys. The place contains 1828, and the canton 9905 inhabitants, on a territory of 125 kiliometres, in 13 communes.

LIOSK, a town of Lithuania, in the palatinate of Troki; 20 miles W. of Grodno.

LIOTARD, John Stephen, in *Biography*, a painter in enamel, crayons, and miniature, who was born at Geneva in 1702. He went to Paris to ſtudy in 1725, and thence accompanied the marquis de Puiſieux to Rome, where the earls of Sandwich and Beſborough engaged him to accompany them to Conſtantinople. There he became acquainted with ſir Everard Fawkener, our ambaſſador, who perſuaded him to come to England.

He attempted to make himſelf conſpicuous by adopting the habits and manners of the Levant, and acquired by that and his talents, which were far from contemptible, (particularly in enamel,) a conſiderable degree of encouragement among the nobility and gentry of this country. But his pictures want grace and taſte; he was too cloſe a copyiſt of what he ſaw, and did not make his pictures pleaſing enough to hold his practice when Roſalba became his competitor in crayons.

LIP, or Lips, in *Anatomy*. See Deglutition.

Lip, *Cancer of*, in *Surgery*. Such caſes as uſually go under the denomination of cancers of the lip, are attended with conſiderable variety, both in regard to the manner in which they begin, and the appearances which they put on in their progreſs. It is often exceedingly difficult to pronounce, with certainty, whether particular ulcers of the lips ought to be called cancers or not. For, if we can truſt to the reports of ſurgical authors, very inveterate ſores upon the lips are frequently excited and kept up by a diſordered ſtate of the abdominal viſcera, and many inſtances at firſt taken for cancers, have in the end yielded to different remedies. Thus, a painful induration in the lip, which was ſuppoſed to be an occult cancer, is recorded to have been cured by the employment of emetic and purgative medicines, eſpecially the helleborus niger. (Jourdain, Maladies de la Bouche, tom. ii. p. 172.) Richter and other continental ſurgeons conſider it as aſcertained, beyond doubt, that many bad ulcers of the lips are connected with gaſtric diſeaſes, by which we are to underſtand diſorders of the viſcera ſubſervient to digeſtion, as the ſtomach, liver, bowels, &c. We are informed of a malignant-looking ſore of the lower lip, which proceeded from the projection of an unnaturally long inciſor tooth of the upper jaw, and which healed of itſelf as ſoon as the irritating tooth was extracted. (Jourdain, l. c. p. 196.) Scorbutic ſores upon the lips have ſometimes been miſtaken for cancers, and at length yielded to anti-ſcorbutic medicines. (Metzger Adverſaria, vol. ii.) Even ſores which have been occaſioned on the lips by chilblains, have ſometimes been erroneouſly regarded as cancers. Many ulcers on the lips which at firſt are quite of an harmleſs nature, are rendered malignant by the ſtimulating and cauſtic applications made uſe of, almoſt every unhealthy ſore in this ſituation attracting a ſuſpicion of carcinoma, and leading the haſty practitioner to dreſs it with irritating and eſcharotic ſubſtances. But the caſes which, of all others, are the moſt liable to be miſtaken for cancers of the lip, are venereal ulcers. Theſe are ſaid to have been ſometimes cut out by indiſcriminating ſurgeons, who, inſtead of ſeeing the wound heal favourably, have had the double mortification of witneſſing the return of more extenſive ſyphilitic ulceration in the part, and on the adminiſtration of mercury, having their blundering conduct detected by the offended patient, and expoſed to the obloquy of the world.

Whoever meditates on the foregoing facts, muſt be convinced of the impropriety of making haſty and poſitive deciſions, concerning the nature of ulcers on the lips. Bad ill-looking ſores are, indeed, formed with particular frequency on theſe parts of the face; but moſt of them are not of ſo malignant and incurable a character, as to merit the appellation of cancer. Many of them, as we have already ſtated, are exaſperated by wrong modes of treatment, and the lips, in conſequence of their inceſſant motion, are unqueſtionably a diſadvantageous place for cicatrization in general.

The diſeaſes to which cuſtom has aſſigned the name of cancer of the lip, may begin in different ways, and aſſume various appearances. They often commence in the form of a warty excreſcence, which, after attaining a certain ſize, breaks out into ulceration. They frequently come on in the ſhape of a phagedenic ulcer; while, in other inſtances, they begin as a hard lump, which at laſt falls into the ulcerated ſtate. In ſome caſes much pain is experienced; in others, the degree of ſuffering is inconſiderable. The occaſional cauſes are ſubject to equal variety. Sometimes the diſeaſe appears to come on of itſelf. In other examples, its origin is referred to a ſmall pimple, chap, or excoriation of the lip. We are told of a caſe, where a cancerous ulcer of the tongue and one ſide of the mouth occurred, in conſequence of inadvertently drinking ſome liquor, with which an ulcerated cancer of the breaſt had been waſhed. Gooch, Chirurgical Works, vol. ii. p. 127.

The lower lip is that which is commonly affected, the upper one being attacked only in a ſmall proportion of the caſes which preſent themſelves in practice. It is alſo alleged, that the diſeaſe is much more frequent in the male than the female ſex. (Richerand, Noſographie Chirurgicale, tom. iii. p. 253, edit. 2.) One important fact, in which all the beſt informed ſurgeons agree, is, that cancers of the lips and face in general are far leſs malignant than carcinoma of the breaſt, or at leaſt, admit of being effectually extirpated with the knife or cauſtic with more extenſive ſucceſs. The prudent ſurgeon, before removing a cancerous breaſt, feels himſelf obliged to explain the poſſibility of a return of the diſtemper; but when the lip is the part affected, and care is taken to remove every particle of the diſeaſe, he may be much bolder in his promiſes.

The medicines uſually tried in other caſes of carcinoma, may be exhibited in thoſe of cancerous lips. (See CANCER.) The internal employment of arſenic has in particular been much praiſed. On the whole, however, we have little confidence in any thing but extirpation, and it is only in doubtful caſes, that delaying the operation to try the effect of medicines or applications can be very juſtifiable. Waſting time till the diſeaſe affects the lymphatic glands under the jaw, or ſpreads ſo extenſively, that the wound after the operation cannot be united, is ſerious miſconduct in the ſurgeon, for the ill conſequences to the patient are irremediable. In the firſt caſe, the diſtemper under the jaw moſtly cannot be taken away; in the ſecond, if the lower lip be affected, as is commonly the caſe, great deformity, imperfect ſpeech, and (what is more terrible) a continual ſlavering muſt for ever remain; or at moſt, admit of only ſlight palliation by artificial contrivances.

There are now only two modes of extirpating cancers of the lip; one with cauſtic, the other with a knife.

In theſe caſes, cauſtic has been very extenſively employed, and ſucceſs may be expected from the method, when the whole of the diſeaſe admits of being at once deſtroyed by a ſingle application. But when the cauſtic muſt be repeatedly uſed, it not only proves in many inſtances ineffectual, but often aggravates the diſeaſe. Nearly all the varieties of cauſtic have been employed by different practitioners. The great thing is to have one that is exceedingly active, and the kali purum with quick-lime is as good as any. We have read of a caſe which was cured by means of a burning glaſs, though we do not perceive any advantage that this plan can have over the employment of cauſtic. Comte, Hiſtoire de l'Acad. Royale de Médecine, ann. 1776.

Let it not be inferred from the foregoing obſervations, that we are advocates for the uſe of cauſtic, as we frankly own, that although it was our duty to mention the practice, we ſhould be aſhamed of adopting it. In every caſe where cauſtic can be employed, the knife can always be uſed with advantage. It does its office more quickly, and with leſs pain, at the ſame time that it accompliſhes the removal of the diſeaſe, and ſurrounding ſubſtance with greater certainty and exactneſs. But the grand recommendation is, that the wound made with a cutting inſtrument is ſuch as can be evenly united by the firſt intention.

Notwithſtanding the teſtimony of the beſt ſurgical writers, in ſupport of the very frequent ſucceſs attending the extirpation of cancers of the lip, one modern author is adverſe to making ſuch attempt at all, either with cauſtic or with the knife. (Jourdain, Mal. de la Bouche.) This doctrine, we confeſs, ſurpriſes us a good deal, as being ſo repugnant to the ſentiments which we have derived, not merely from the moſt accurate books, but from the obſervation of numerous cures. If M. Jourdain has, in his own individual practice, met with many inſtances of a return of the diſeaſe after the operation, we cannot help ſuſpecting, that his mode of extirpation muſt have been faulty and incomplete.

Although it is an important maxim in the operation, to make the wound of ſuch a ſhape as will admit of an even union, it is a ſtill more important point to remove every particle of the diſeaſe. The majority of relapſes are unqueſtionably imputable to the neglect of this material object, and not to the incurableneſs of the complaint. It is always better to remove too much rather than too little, for the lips are ſo very yielding, that, in numerous caſes, nearly the whole lip has been cut away, and yet the wound has been united without deformity. At the time that we are writing this article (namely Auguſt 1811,) there is in St. Bartholomew's Hoſpital a caſe, where the greater part of the lower lip was removed by Mr. Vincent on account of a cancer; but, notwithſtanding this great loſs of ſubſtance, the edges of the wound were eaſily brought into contact.

The operator ought not only to take away all that is manifeſtly ſwollen, ulcerated, or indurated; he ſhould be careful likewiſe not to leave any parts which are at all diſcoloured. In ſhort, it is ſafeſt to make the inciſions at ſome little diſtance from the perceptible boundaries of the diſtemper. The extent of the diſeaſe upon the inſide of the lip will always demand careful examination.

When the whole lip is thoroughly cancerous, the practitioner is under the neceſſity of cutting every particle of it away, in which circumſtance the wound will not admit of union, but muſt heal by granulations. On the contrary, when the extent of the diſeaſe is more moderate, the operator ſhould always make the wound in the manner of that practiſed for the cure of the hare-lip, ſo that it may be united by means of the twiſted ſuture. (See HARE-LIP.) As the lips are very tenſile, this method is generally practicable; and it is well known, that the twiſted ſuture may be ſucceſsfully employed, though two-thirds of the lip have been cut away.

The ſooner the operation is undertaken, the greater is the chance of ſucceſs. Caſes only become irremediable through delay, or an ineffectual uſe of cauſtic or the knife. The more extenſive the malady is, the more difficult it is to cure. The caſe indeed is paſt relief, when the diſtemper has ſpread to the bones, the gums, the glands beneath the jaw, or any other parts which cannot be removed. The ſurgeon, however, muſt relinquiſh no caſe where there is a poſſibility of making an effectual removal of the morbid parts.

The mere magnitude of a cancerous tumour is not prohibitory of the operation. In one caſe, exciſion was performed moſt ſucceſsfully, notwithſtanding the excreſcence was ſo large as to hang down on the breaſt. (Le Dran, Obſerv. tom. i. p. 78.) In another example, the operation had the happieſt conſequences, although the inſide of the lip and cheek felt as rough as if it had been ſmeared all over with ſand. (Richter's Anfangſgr. &c. Band 2, p. 326.) Richerand upbraids with timidity, ſurgeons who are ſtopped by the extent of the malady, and he contends, that extirpation ſhould be undertaken, even though it be neceſſary to ſeparate the ſoft parts from the lower jaw bone, provided the glands under the chin are free from diſeaſe. He informs us, that Chopart, after removing in one caſe the whole of the lip, and a portion of the cheek, was obliged to cover the denuded jaw with the integuments of the neck. Notwithſtanding ſuch loſs of ſubſtance, the wound healed; the opening of the mouth remained for a time contracted; but it ſerves (ſays this author) for the admiſſion of aliment, and gradually becomes larger, the power of better pronunciation alſo returning. Noſographie Chirurgicale, tom. iii. p. 252, edit. 2.

Whenever the caſe is ſuch, that an attempt to unite the wound can be practiſed, the ſurgeon muſt take away a triangular portion of the diſeaſed lip, ſo that the inciſion may reſemble the letter V, and its edges be eaſily brought together with the twiſted ſuture, as in the operation for the hare-lip.

The union of wounds of the lower lip is an exceedingly important object, ſince, beſides the deformity, a more ſerious grievance ariſes from the ſeparation, namely, the continual involuntary diſcharge of the ſaliva, which is naturally confined within the mouth by the lower lip. Nothing can be more annoying than ſuch an infirmity, and by impairing digeſtion, it alſo proves extremely hurtful to the health. A patient whoſe lower lip is ſo extenſively diſeaſed, that extirpation cannot be effected, without inducing this affliction, is in a truly pitiable ſtate.

That the health ſuffers greatly from the inceſſant loſs of the ſaliva, is a fact confirmed by numerous caſes. A woman had a cut through her lower lip, and the wound, being neglected, ſuppurated, and its margins healed. The conſequence was that the ſaliva conſtantly eſcaped from her mouth, and from being a healthy-looking woman before the accident, ſhe became rapidly emaciated, afflicted with ſtomach complaints and difficulty of digeſtion. Tronchin, being conſulted, ſaw that her indiſpoſition proceeded from the loſs of a nutritious fluid. He adviſed uniting the diviſion by the operation for the hare-lip. This was actually done by Ferrand. The loſs of the ſaliva was prevented, and the patient ſoon regained her health and good looks again.

It would ſeem that children can bear the loſs of a large quantity of the ſaliva better than adults. A little girl, ſix years old, was brought into the hoſpital of St. Louis, afflicted with a gangrenous carbuncle, that had not only ſpread to the whole lower lip, and ſoft parts about the chin, but alſo to the body of the jaw. The ſloughing having ſtopped, the dead parts were detached, the body of the lower jaw-bone ſeparated from the rami at the places of anatomical diviſion. In this caſe, the circumſtance particularly worthy of notice is, that although the ſaliva was inceſſantly running out of the mouth, ſo as to wet all the girl's clothes, ſhe enjoyed, during the ſix months ſhe was in the hoſpital, a good appetite, and had every appearance of being well nouriſhed. See Richerand's Noſographie Chirurg. tom. iii. p. 255, edit. 2.

Lip, *Hare*,
Lip, *Preternatural Fiſſure of*, } See Hare-lip.

Lip, *Wounds of*. In theſe caſes the chief indication is to place the edges of the diviſion in exact and even contact, in order that they may unite by the firſt intention. The twiſted ſuture will generally be found the moſt advantageous for this purpoſe. It is to be applied in the manner explained in the article Hare-lip, in conjunction with narrow ſtrips of adheſive plaſter, and a bandage that will preſs forward the integuments of the face. Whether one or two pins ought to be uſed muſt depend upon the length of the diviſion. When the wound is lacerated, or contuſed, it often cannot be hindered from ſuppurating, and union by the firſt intention is prevented. However, in ſuch inſtances, a pin may frequently be employed with benefit, as a partial adheſion may take place, though the agglutination is not general. And even when theſe wounds ſuppurate, maintaining the edges near each other with ſtrips of adheſive plaſter will materially leſſen the breadth of the ſcar, and expedite the cure. Sometimes it may be proper to poultice a contuſed or lacerated injury of the lip, where there is no immediate proſpect of adheſion, and the part has a ſloughy aſpect; but this plan ſhould only be continued till the wound puts on a cleaner appearance and begins to granulate; the proper method being now to apply adheſive plaſters, and a pledget of any common unirritating ointment.

Lip *of a Horſe*, in the *Manege*, is the ſkin that covers the ſides of the mouth, and ſurrounds his jaws. A horſe is ſaid to arm or guard himſelf with his lips, when his lips are ſo thick that they cover their bars, and keep off the preſſure of the curb.

LIPA, of λιπος, *fat*, a word uſed frequently by Hippocrates to expreſs any thing fat or oily. He calls certain ſtools, which have a fatty appearance, by this name. Theſe are eſteemed a ſign of great colliquation. He alſo applies it to a ſort of fatty ſubſtance, often ſeen ſwimming on the ſurface of the urine like a ſpider's web: this the ſame great author gives as a ſign of a conſumption.

Lipa, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 32 miles W.N.W. of Sluck.—Alſo, a town of Croatia, on the river Dobra; 10 miles S.W. of Carlſtadt.

LIPARÆUS Lapis, in the *Natural Hiſtory of the Ancients*, the name of a ſtone uſually found in Lipari, one of the Æolian iſlands, and brought thence in the time of the Greeks among the pumices, of which that place always afforded them a large quantity.

It was a ſmall ſtone, about the bigneſs of a filbert, of an irregular and uncertain ſhape, and porous and friable conſtitution, like that of the pumices, but more eaſily falling to pieces on rubbing between the fingers than even the ſofteſt of them; the colour was a duſky grey, and the whole external ſurface plainly ſhewed that it had ſuffered changes by the means of fire. The ſtone at preſent, however, is ſo little regarded, that the writers on ſuch ſubjects have even forgot to name it. They are ſometimes brought to us, to this day, among the pumices from the burning mountains, but are not regarded.

LIPARI, in *Geography*, a volcanic iſland, or rather a group of ſuch iſlands, in the Mediterranean, about twenty-four miles from the N. coaſt of Sicily. They were formerly called Æolian *Iſlands*, which ſee; and now *Iſole di Lipari*, from the name of the chief of them. Theſe iſlands were anciently known to be volcanic, and called Volcanian, but it is in modern times that their volcanization has been conſidered as an object of intereſting reſearch to philoſophers, among whom M. de Luc, ſir W. Hamilton, Dolomieu, and Spallanzani have diſtinguiſhed themſelves. Theſe iſlands are commonly reckoned ten in number, though ſome by omitting and others by comprehending ſome barren rocks, have diminiſhed or increaſed their number. The largeſt is Lipari, being 19½ Italian miles in circuit. Accordingly this iſland, from its extent, the city which renders it illuſtrious, the number of its inhabitants, its agriculture and commerce, claims pre-eminence above all the others by which it is ſurrounded. Nor is it leſs important in the eſtimation of the naturaliſt from the quantity, variety, and unuſual beauty of the volcanic products which it contains. It is well known, by the teſtimony of Diodorus (l. 5.), that all the Æolian iſles were ſubject to great eruptions of fire, and that their craters and mouths were viſible in his time. As to Lipari, however, very few memorials have been preſerved of its ancient conflagrations. Of the antiquity of the iſland, and of its exiſtence before the Trojan war we are certain, ſince we learn from Homer, that, after the taking of Troy, Ulyſſes landed there, and was treated with the utmoſt urbanity and courteſy by king Æolus, during the whole month of his continuance there (Odyſſ. l. 10.); and though we allow to the poet the uſual licence of poetry, it is ſtill moſt certain that he could not have named this iſland, and the city it contained, unleſs they exiſted at the time when he wrote his poem, above

3000 years ago. But if we conſult other ancient and credible writers, we ſhall find that before Æolus, Liparus reigned in this iſland, and that from him it took its name, being before called " Meiogonis," or, according to others, " Meligunis." The antiquity of this iſland may alſo be inferred from the manner of its production by ſubterraneous eruptions, in which the decompoſition of volcanized matters is neceſſary, which requires a conſiderable interval of time. If, therefore, Lipari had inhabitants and cities, and was a cultivated country before the deſtruction of Troy, it is evident that it muſt have exiſted many ages prior to that event. But from the time when mention is made in hiſtory of this iſland to the preſent day, it is pretty certain that no true eruption or current of lava has taken place in it; for if this had been the caſe, ſome memorial would have been preſerved of it as well as of thoſe of Stromboli and Vulcano. The ſtoves and the warm baths of Lipari are the only places in the whole iſland where any ſigns remain of unextinguiſhed volcanos. Spallanzani made a circuit of this iſland for the purpoſe of firſt examining its ſhores, and he then aſcended its mountains in its interior parts. In examining its ſhores, he began with the city of Lipari, which extends along the ſhores in the form of an amphitheatre; and in his reſearches in the harbour itſelf, under the caſtle of the city, he found that it is erected on an immenſe rock of lava, that riſes perpendicularly from the water, and is entirely deſtitute of all vegetation, except a few ſtalks of the Indian fig (Cactus opuntia, Linn.) which grew in its fiſſures. This lava has for its baſe feldſpar, is of a fine compact grain, of a ſcaly fracture, dry to the touch, and gives ſparks, like flint, with ſteel. The colour is cinereous, approaching in many places to that of lead. This lava is joined to large maſſes of glaſs, which form a whole with it, without any ſeparations or diviſions in the middle. It is therefore the ſame lava, either retaining its own nature or tranſmuted into glaſs. This glaſs, like the lava, gives ſparks with ſteel; but the lava is opaque, whereas the glaſs, in the angles and thinner edges, has a conſiderable degree of tranſparency. The ancient exiſtence of fire in this place is evinced by another circumſtance, *viz.* that the vitreous ſubſtances already noticed are frequently accompanied by pumice, which are, in fact, only an imperfect glaſs. In viewing the ſteep maſſes of glaſs and lava, which riſe perpendicularly from the ſea, like a wall, they are ſeen to be interſperſed with different ſtrata of pumice, which is of two kinds; the one heavy and compact, the other light and porous, and both of a cinereous colour. The firſt ſort is of the ſame nature with the lava of the rock; but the other kind is rather ſcaly than filamentous, and its ſcales have a degree more of vitrification than the other. This pumice is uſually a continuation of the other, and, according to our author, derives its origin from the greater degree of heat which it has ſuſtained. Upon attentively examining this mixture of lava, glaſs, and pumice which forms the body of the rock, it appeared evident that there muſt have been ſeveral currents that had flowed down the ſides, and, perhaps, from the ſummit, of the contiguous mountain Della Guardia, into the ſea; ſince the direction of their deſcent is found on that ſide, and even the filaments of the pumices point towards that mountain. The lava, glaſs, and pumice exhibited neither feldſpars, ſhorls, nor any other extraneous body, either, as our author conceives, becauſe they have melted by the fire, or, perhaps, becauſe they never exiſted in them. The lava and glaſs of the rock, when expoſed to the furnace in ſeparate crucibles, fuſed into a light-grey glaſs; the globules which before appeared in them melting at the ſame time; during liquefaction theſe ſubſtances, which filled only one quarter part of the crucible, ſwelled ſo much, that they roſe ſeveral times above the edges of the crucible, and flowed over its ſides. The two kinds of pumice, though both derive their origin from the ſame feldſpar, which is the baſe both of the lava and the glaſs, afford different reſults in the ſame fire; ſince their volume, inſtead of being augmented, is diminiſhed, only retaining its former colour.

The haven of Lipari forms a curve in the ſhore, which to the ſouth begins at the foot of the Monte Capiſullo, and ends to the north-eaſt at the bottom of the Monte della Roſa. After having examined that part of the ſhore which is contiguous to the harbour, lying under the caſtle, and on the right ſide of Monte Capiſullo, our author made the circuit of the remainder of that curve to the baſe of Monte della Roſa. The objects that here attracted his notice were firſt a tufa, which the induſtry of the inhabitants had converted into a ſoil ſuitable to ſmall vineyards, and next a maſs of crags and precipices, partly fallen into the ſea, and partly threatening to fall; among which, beſides ſcoriæ of an iron colour, he met with beautiful volcanic breccias of lava of a petroſiliceous baſe, containing ſmall particles of glaſs and pumice. At the foot of the Monte della Roſa, where the harbour of Lipari ends, our author perceived on the ſhore a ſtone, which, from its ſingularity, drew his attention. It formed a rock riſing in part above the ſea, and in part concealed by the water. It was at firſt taken for a jaſper: its ground was of a red-blood colour; it gave ſparks ſtrongly with ſteel, was of a rather fine grain, and had almoſt the hardneſs of quartz. On a more attentive examination this ſtone was perceived not to be ſimple like the jaſper, but of a compound formation, containing in it reddiſh ſcales of feldſpar and ſhorls, which gave it the character of that kind of porphyry which has for its baſe a hard horn-ſtone. This ſubſtance our author, after careful inveſtigation, cannot exclude from the number of true and real lavas, though he cannot affirm that its redneſs is an effect of calcination, as is the caſe in other lavas, ſince of this it does not exhibit the ſlighteſt indication. The reaſons of fact on which Spallanzani grounds his opinion, that this porphyritic rock has paſſed into the ſtate of lava, are two; the great number of minute cells it contains in many parts of it, and the direction of thoſe cells. Hence he concludes, that this ſtone is not only a true porphyritic lava, but that it once flowed from the mountain to the ſea, and in its motion the naturally circular figure of its pores or cells was changed into an oval. The ſame appearance has always been obſerved, on a ſmaller ſcale, in re-melted lavas, and glaſſes. All the ſpecies of this kind of lava are not, however, of a blood-red colour; ſome of them are of a duller red, though the component principles of both are eſſentially the ſame. This lava, when fuſed in the furnace, doubled its volume, and its upper part aſſumed a vitreous convexity, which was ſmooth, ſhining, ſemi-tranſparent, and of a greeniſh tincture; but internally it was a very black vitreous ſcoria, extremely porous, and ſufficiently hard to give ſparks with ſteel.

In purſuing his tour our author found that Lipari, like the other Æolian iſles, is at its baſe more or leſs corroded by the ſea, which is frequently in a ſtate of violent agitation: the lower excavations cauſe the parts above them to give way, and, in a ſeries of years, great maſſes fall into the ſea. To this the nature of the lava, which is full of cracks and fiſſures, conſiderably contributes; not to mention the influence of the humidity of the atmoſphere, and other deſtructive elements. Large heaps of theſe fragments accumulate on the ſhore, and make room for others, and thus a gradual diminution of the iſland takes place. Beyond the harbour and the porphyritic rock, our author found the ſea forming a kind of bay within the land, round which a few cottages are built, affording ſhelter to a ſmall number of inhabitants, who ſubſiſt by the profits of a vineyard that ill repays their labour. The name of this place is Canneto; and above it is a current of lava, of an argillaceous baſe, ſimilar to that of the Arſio in Iſchia. At the diſtance of three miles from the haven of Lipari is Campo Bianco (the White field), ſo called, becauſe it is a lofty and extenſive mountain, compoſed entirely of white pumices. For the nature, production, and properties of *Pumice*, we refer to that article. The mountain, which is a prodigious maſs of pumice, riſes almoſt perpendicularly from the ſea, and, ſeen at a diſtance, appears to be about a quarter of a mile in height, and above half a mile in breadth. No plants grow upon it, except a few without fruits, like thoſe on the tops of the Alps. Its ſides are ſtreaked with numerous furrows, widening and deepening as they approach the bottom, and formed by the rains, which eaſily corrode and excavate a ſubſtance ſo ſoft and yielding as pumice. The ſea at the bottom has likewiſe occaſioned great devaſtations, by means of which is laid open to view a large vein of horizontal lava, on which the laſt wave dies away when the ſea becomes calm. The formation of this lava was, therefore, prior to the vaſt accumulation of pumices which reſt upon it. This maſs of pumice is an aggregation of numerous beds, or ſtrata, of pumices, ſucceſſively placed on each other, diſtinguiſhable by their colour and by their projection from the mountain. Some of theſe pumices are ſo compact that the ſmalleſt pore cannot be diſcerned, nor do they exhibit the leaſt trace of a filamentous nature. With a lens they appear to be an irregular accumulation of ſmall flakes of ice. Others are full of pores and vacuities of a larger ſize, uſually round; and their texture is formed by filaments, and ſtreaks, generally parallel to each other, and of a ſhining ſilvery whiteneſs. Of theſe pumices there are three kinds, which the people of Lipari dig for ſale. One kind is employed in poliſhing different ſubſtances, and the other two kinds are uſed in the conſtruction of arched vaults, and the corners of buildings. There are other kinds which merit the attention of the natural hiſtorian. In examining theſe pumices our author obtained the following reſults:

	1ſt Species of Campo Bianco.	2d Species.	3d Species.	4th Species.	Pumice of the rock of the caſtle of Lipari.
Silex	60.3	80	80	61	63
Alumine	23	6	4	22.7	24
Magneſia	6	3	2	6	5.6
Lime	6	4.7	4	5.8	3
Iron	3	4.8	5.3	3	2

Beyond Campo Bianco and its adjacent hills, riſes a mountain of another kind, called the Monte della Caſtagna, which, in the part of it deſcending to the ſea, is about one mile in extent, and above four miles in circumference. This mountain, according to Dolomieu and our author, is entirely compoſed of enamels and glaſſes. For the deſcription of theſe in their number and variety, we muſt refer the reader to the work before us. Campo Bianco and the Monte della Caſtagna, though apparently iſolated, are in reality a connected group, taken in its whole extent, having a circuit of eight miles; nor is the extent of its vitrifications leſs, if in theſe we include likewiſe the pumices, which are in fact only a leſs perfect glaſs. The ſterility of theſe mountains is a conſequence of their vitreous nature, which, in the courſe of ſo many ages, has not been decompoſed into a vegetable earth: if we except a few lichens attached to the fiſſures of the glaſſes, there is no veſtige of a ſingle living vegetable over the whole Monte della Caſtagna; and on Campo Bianco they are extremely rare. Beyond the pumices, the lavas again appear, beginning from the "Punta del Segno Nero," and extending in a chain of ſeveral miles, which on the ſide of the ſea deſcends in precipices and craggy declivities: and proceeding further, the ſea makes an incurvature and forms a ſmall bay, called the Valle di Muria, on the ſides of which riſe high and ſteep rocks of lava, half demoliſhed, and among the lava enamels and pumices. In examining the interior of the iſland, Monte San Angelo, ſituated to the north of the city of Lipari, is the higheſt mountain, on the ſummit of which is a circular plain, ſurrounded by eminences ſhelving towards the inſide, which M. Dolomieu imagined to be the remains of an ancient crater, and which he ſuppoſes to have been the firſt that was formed in the iſland, about a mile above the ſea, through which the volcano burſt forth, and which ſerved as a baſe and ſupport for the other mountains that were thrown up afterwards. Soon afterwards roſe its companion, the Monte della Guardia, which looks towards the ſouth, and little inferior to the other in height. Theſe two mountains formed two iſlands in the ſea, which, enlarging each its reſpective baſe, united into one. To theſe two mountains ſubſequent eruptions made new additions, until at length the whole iſland of Lipari was produced, which, from the eroſions of the rain and ſea, is now certainly leſs than it once was.

Lipari, if we except ſome few flat places and practicable declivities, which the inhabitants have rendered cultivable by great labour, is a ruinous pile of horrid precipices, rugged cliffs, and enormous maſſes; and there is no ſummit, nor projecting part of a mountain, which does not exhibit manifeſt indications of its future fall and deſtruction. The materials of which theſe ruins are formed are pumices, enamels, and glaſſes, ſimilar to thoſe which we have already mentioned.

The celebrated ſtoves of Lipari have exerciſed the curioſity of travellers. Theſe lie four miles W. of the city, and ſomewhat beyond the ſummit of a mountain, which, next to thoſe of San Angelo and della Guardia, is one of the higheſt in the iſland. The road from the city to the ſtoves is formed by a deep excavation, chiefly the work of rain-waters, in an immenſe maſs of tufa. Our author conceives that the volcanic tufas have been formed by ſlimy eruptions; without denying, however, that aſhes, ſand, and other ſubtile matters ejected by volcanoes, and penetrated either by the rain-waters, or thoſe of the ſea, where they covered the baſes of the burning mountains, have been conſolidated into ſome tufas. The tufa of Lipari, to which we now refer, has every appearance of having been an earthy current in our author's opinion. It begins at about 100 paces from the city, and continues, without interruption, to beyond the ſummit of the Monte della Stufa, or Mountain of the Stoves. (See TUFA.) The ſtoves, terminating a deſcent of about 200 feet in length, form a group of four or five caves, more like to the dens of bears than the habitations of men, and exhibiting much leſs art than the edifices formed by the beaver. Every cave has an opening at the bottom, through which the warm and tumid vapours enter, and another in the top, through which they paſs out. On one of theſe ſtoves the thermometer ſtood at only 48$\frac{2}{3}$°; but the vapour poſſeſſes ſomewhat of a ſuffocating nature. The ſtoves now retain little more than their name, and whatever may have been their ſuppoſed virtue in the cure of diſorders, they are now nearly deſerted. Under the ſtoves, and the adjacent ground, there is reaſon to believe, that ſome remains of ſulphureous conflagrations ſtill continue.

Lipari, we have already obſerved, is the largeſt, and it is alſo the moſt populous of thoſe called the Æolian iſles; the number of its inhabitants amounting to between nine and ten thouſand, moſt of whom reſide in the city of the ſame name. If the iſland be divided into four parts, about 2½ will be found to be cultivated, and the remainder overgrown with wood, and barren. Theſe barren tracts, however, are gradually converted into fruitful fields, from a kind of neceſſity ariſing from the continually increaſing population of the iſland. Lipari produces cotton, pulſe, and olives, in ſmall quantities. The corn is ſcarcely ſufficient for the ſupply of the city. The principal of the uſeful productions of this iſland are the grapes, of which there are ſeveral kinds. The firſt furniſhes the common wine that is drank in the iſland, and of which they export annually two or three thouſand barrels. The paſſole and paſſolina, as they are called in the iſland, are two other kinds of grapes that are dried. The laſt is that ſort which is uſually called the Corinthian grape. Of this they commonly ſell 10,000 barrels annually; and of the other about 12,000. From a fourth kind of grape is made the famous Malmſey of Lipari; which is a wine of a clear amber colour, generous and ſweet. The grape producing this wine is ſcarce, and does not furniſh more than 2000 barrels annually, which are ſold for foreign markets, as well as the paſſole and paſſolina. The vintage is in the month of September, which is a ſeaſon of relaxation and feſtivity to the Lipareſe. Another plant of domeſtic uſe to the Lipareſe, if it does not form a branch of foreign commerce, is the Indian fig (Cactus opuntia, Linn.) Nothing can be more wretched than the fiſhery of Lipari. In June and July they fiſh for coral; but owing to a want of ſkill, this fiſhery is very unproductive. At Lipari large and ſmall cattle are very ſcarce; and the few oxen and cows which are ſlaughtered there are brought from Sicily, and are very lean. Of wild quadrupeds, the country only produces rabbits, which make their burrows in the mountainous parts, where the volcanic matters, principally of the tufaceous kind, permit them to dig with their feet. The birds ſtationary here are but few, *viz.* the partridge, green-finch, ſparrow, gold-finch, horn-owl, and raven. Of migrating water-fowls, here are different kinds of ſea-gulls and the cormorant. The birds of paſſage are the turtle-dove and the quail, which come for a few days in April and September. Several kinds of ſwallows are common.

Foreign commerce has begun to be introduced into the iſland by the mariners; they every year buy, at the fair of Sinigaglio, linen, muſlins, veils, and other commodities of that kind; and ſell them at Meſſina, Catania, Palermo, and other parts of Sicily. The trade is very advantageous to the country, and many have acquired conſiderable wealth; though it injures the fiſhery and raiſes the price of fiſh. Strabo, Diodorus, and Dioſcorides ſay, that the ſulphate of alumine (alum) was procured in great abundance at Lipari; but none of this ſalt is now extracted in the iſland.

The political adminiſtration of Lipari is compoſed of a criminal judge, a fiſcal, a governor, who has the chief authority both in military and civil affairs, and who is commonly an old invalid; and a civil judge. The biſhop, ſeventeen canons of the firſt order, and fourteen of the ſecond, and from 120 to 130 prieſts, form the eccleſiaſtical eſtabliſhment. The Lipareſe are, in general, of a prompt and lively wit, ready to learn, of acute penetration, and very deſirous of obtaining knowledge. A beggar is ſcarcely ever found in this iſland; for the pooreſt perſons have ſome ſmall piece of ground which they cultivate, and by the produce of which they live. The natives are rather of a large ſize, robuſt, and comely. The heat of the ſun, however, injures their fine complexions, producing tanned ſkins and ſwarthy countenances. The Lipareſe, in general, value themſelves upon being good mariners, both in theory and practice. Spallanzani's Travels in the Two Sicilies, &c.

Lipari, an ancient city of the above iſland, forming an amphitheatre along the ſhore, with a chain of mountains behind it, not of an extenſive circuit, and conſiſting rather of narrow alleys than ſtreets. The caſtle is ſurrounded with a wall, on which are erected a few cannon, and is defended by a ſmall garriſon. The houſes are indifferent buildings; but three edifices are diſtinguiſhable from the reſt; *viz.* the palace of the biſhop, the houſe of the governor, and the cathedral church. The latter contains very coſtly ſacred utenſils, a great quantity of plate, and a number of ſilver images, among which is the ſtatue of St. Bartholomew, their patron ſaint. The value of this treaſure is ſaid to amount to 90,000 Neapolitan ſcudi; the ſcudi being worth about 4*s.* 3*d.* N. lat. 38° 35′. E. long. 15° 12′.

LIPARIA, in *Botany*, ſo named by Linnæus, in his ſecond *Mantiſſa*, in alluſion either to the ſmooth or ſleek habit of L. *ſphærica*, from which his idea and character of the genus was taken, or to its rich and ſplendid appearance, for the Greek word λιπαρος will juſtify either explanation. Profeſſor Martyn gives the former; we prefer the latter.—Linn. Mant. 156. Schreb. 499. Willd. Sp. Pl. v. 3. 1114. Mart. Mill. Dict. v. 3. Thunb. Prodr. 123. Ait. Hort. Kew. ed. 1. v. 3. 48. Juſſ. 353.—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, very obtuſe at the baſe, divided half way down into five acute ſegments, the lowermoſt of which is very long, elliptical, and reſembling a petal. *Cor.* papilionaceous, without any ſpurs or elongations to the keel or wings. Standard oblong, folded, ſtraight, reflexed at the ſides. Wings oblong, ſtraight, narrower at the baſe, two-lobed at their inferior margin. Keel lanceolate, ſlightly aſcending, divided deeply at the baſe. *Stam.* Filaments in two diſtinct ſets; one ſimple; the other in nine diviſions, which are thread-ſhaped, three of them ſhorter than the reſt; anthers ovate. *Piſt.* Germen ſeſſile, very ſhort; ſtyle thread-ſhaped, of a moderate length; ſtigma ſimple. *Peric.* Legume ovate. *Seeds* few.

Eſſ. Ch. Calyx in five ſegments, the lower one elongated. Wings of the corolla two-lobed at the lower ſide. Three of the united ſtamens ſhorter than the reſt. Legume ovate.

This ſplendid genus of ſhrubs, from the Cape of Good Hope, is in every reſpect cloſely allied to *Borbonia*, next to which it ought to ſtand in the Linnæan ſyſtem, though Murray, who has been heedleſsly followed by others, widely ſeparated them. *Liparia* differs from *Borbonia* in being truly diadelphous. How far the other characters indicated in their deſcriptions hold good, we have not ſufficient acquaintance with all the ſpecies of either genus to determine, but there is no difference with regard to habit or appearance. Two ſpecies are deſcribed by Linnæus, Mant. 268, 269, and four more indicated with doubt, amongſt which is *Spartium capenſe*, (*Crotalaria oppoſita*, Linn. Suppl. 322.) The reſt ſtand as *Liparia* in Syſt. Veg. ed. 14. 665, making five in all, to which eight are added by Thunberg, and the whole thirteen are admitted by Willdenow. The habit of the genus is rigid, with numerous, ſcattered, ſharp, uſually elliptical, rarely linear leaves, which are either ſmooth, hairy, or ſilky. Flowers, as far as we know, of a fine rich yellow, in terminal heads or umbels. Examples are

L. *ſphærica*. Linn. Mant. 268. Andr. Repoſ. t. 568. Curt. Mag. t. 1241.—Flowers numerous, in bracteated drooping heads. Leaves elliptic-lanceolate, ribbed, ſmooth.—According to Andrews this was raiſed by Mr. Milne, gardener at Fonthill, Wilts. We received it from Mr. Anderſon, curator of the ſplendid collection of James Vere, eſq. at Kenſington Gore. The *ſhrub* is five or ſix feet high, clothed with numerous, ſpreading or recurved, glaucous *leaves*, above an inch long, entire, and ſtrongly ribbed. The large drooping round heads of golden *flowers*, are ſingularly magnificent, accompanied by numerous reddiſh *bracteas*, differing from the leaves chiefly in colour and ſituation. The whole plant unavoidably turns as black as ink in drying. It bloſſoms in May.

L. *graminifolia.* Linn. Mant. 268.—Flowers capitate. Calyx hairy. Leaves linear-lanceolate, ſmooth.—Grows in a ſandy ſoil at the Cape. We have ſeen it in a dry ſtate only, nor is any figure extant. The very narrow *leaves*, an inch or inch and a half long, and about a line wide, are peculiar, as well as the hairy heads of *flowers*, much ſmaller than thoſe of the foregoing. The *branches* are angular and ſmooth.

LIPARIS, a name given by ſome authors to the pinguicula, butter-wort, or Yorkſhire ſanicle.

Liparis, in *Ichthyology*, a ſpecies of *Cyclopterus ;* which ſee.

Liparis *Noſtras*, the name of a ſmall fiſh, common on the coaſts of Yorkſhire, and ſome other parts of England, and called in Engliſh the ſnail, and limax marinus by ſome authors. It is about five fingers long ; on its back and ſides it is of a bright brown, and on the belly of a fine white : theſe are its colours, when freſh taken, for when it has been kept ten or twelve hours, the whole ſurface of the body, except the fins, becomes of a paler and bright brown. The head is thick, and not flat, but rounded ; it has no teeth, but its jaws are both rough like files.

The whole fiſh, head as well as body, is very ſoft and unctuous, and eaſily melts into a ſort of oily liquor. It is caught principally at the mouths of great rivers where they open into the ſea.

LIPAROCELE, from λιπος, *fat*, and κηλη, *a tumour*, in *Surgery*, any kind of tumour compoſed of fat.

LIPAVINA, in *Geography*, a town of Croatia ; 12 miles E.N.E. of Creutz.

LIPCZANI, a town of Poland, in the palatinate of Braclaw ; 60 miles W.S.W. of Braclaw.—Alſo, a town of Moravia, on the Pruth ; 24 miles S.S.E. of Choczim.

LIPENIUS, Martin, in *Biography*, a German Lutheran divine, known only by his works, which are "On the Navigation of Solomon's Ships to Ophir," 1661 ; "A Treatiſe on Chriſtmas-Boxes or New-Year's Gifts :" but his moſt important work is entitled "Bibliotheca Realis," in 6 vols. folio ; conſiſting of a view of all the ſubjects into which the different ſciences ars branched, with a catalogue of the names and works of the various authors who have treated concerning them. Moreri.

LIPES, in *Geography*, a town of Peru, and capital of a juriſdiction, under the viceroy of Buenos Ayres ; 150 miles S.S.W. of Potoſi. S. lat. 21° 40′. W. long. 68° 16′.

LIPETSK, a town of Ruſſia, in the government of Tambov, on the Voronez ; 40 miles W.N.W. of Tambov. N. lat. 53°. E. long. 40° 24′.

LIPETZ, a town of Bohemia, in the circle of Koniggratz ; 9 miles S. of Neu Biezow.

LIPINSKOI, a town of Ruſſia, in the government of Novgorod ; 16 miles S.E. of Novgorod.

LIPNISKI, a town of Lithuania, in the palatinate of Wilna ; 20 miles E.N.E. of Lida.

LIPNITZ, a town of Bohemia, in the circle of Czaſlau ; 6 miles W. of Teutſch-Brod.

LIPNO, a town of the duchy of Warſaw ; 12 miles N. of Dobrzyu.

LIPODERMUS, or Leipodermos, (from λειπω, *to leave*, and δερμα, *the ſkin*,) in *Surgery*, wanting the prepuce.

LIPORANO, in *Geography*, a town of Naples, in the province of Otranto ; 3 miles S. of Tarento.

LIPOTHYMIA, or Lipopsychia, in *Medicine*, from λειπω, *deficio*, and θυμος, *animus*, or ψυχη, *anima*, ſignifies a ſudden faintneſs, or temporary deficiency of the nervous power, and of all the functions depending upon it. It is called alſo *deliquium animi*, ſwooning, ſyncope, &c. See Syncope.

LIPOWE, in *Geography*, a town of Lithuania ; 25 miles N.N.E. of Braclaw.

LIPOWIEC, a town of Auſtrian Poland, on the Viſtula, to which belongs a caſtle on a rock, uſed as a priſon for eccleſiaſtical offenders ; 20 miles W. of Cracow.

LIPPA, a town of Hungary, on the Maros ; 22 miles N. of Temeſwar.

LIPPE-Shaumberg, William, *Count*, in *Biography*, ſon of Albert Wolfgang, count Lippe and Shaumberg, by a daughter of count Oynhauſen, was born in 1724 at London, but was ſent, in 1735, to Geneva, to complete his education. Here he devoted much of his time to the ſtudy of mathematics, as connected with the military art. In 1740 he returned with his brother, and in the following year they were both ſent to the univerſity of Leyden, from which they removed in a ſhort time to Montpellier, in France. At the age of eighteen he repaired to England, and obtained an enſign's commiſſion in the firſt regiment of guards. On the death of his eldeſt brother he returned to Buckebourg, the family reſidence, in Germany, and ſoon after accompanied his father, a lieutenant-general in the Dutch ſervice, during the campaign in the Netherlands, and was preſent as a volunteer at the battle of Dettingen, where he was diſtinguiſhed as well for his good conduct as for his bravery. In the year 1745 he joined the Auſtrian army in Italy, and was promoted, in conſequence of his ſervices, to be a colonel in the Auſtrian army, but he declined acting under the commiſſion. In 1746 he travelled over a conſiderable part of the continent, and from thence he came to England, where he remained till he ſucceeded to his paternal eſtates in 1748, when he repaired to Berlin, to ſurrender into the hands of his Pruſſian majeſty the order of the Black Eagle, which had been conferred on his father. Here he formed an acquaintance with many perſons of diſtinguiſhed literary merit, and he was elected a member of the Academy of Sciences. After this he was diſtinguiſhed as a military man in the Pruſſian army, raiſed a regiment of grenadiers from among his own ſubjects, and was honoured by Frederic with the order of the Black Eagle. In 1754 he eſtabliſhed a foundery at Buckebourg, where he had all the cannon caſt which he afterwards employed in the ſeven years' war againſt the French. In 1756 he entered into a treaty with Great Britain, by which he engaged to aſſiſt his Britannic majeſty in the defence of his German dominions againſt the arms of the French, and to furniſh for that purpoſe a regiment of infantry of a thouſand men, a corps of artillery, and another of carbineers and chaſſeurs. He was preſent at the battle of Minden, and in many other poſts of much danger. In 1758 he was ordered to withdraw his forces from the allied army, and join the Auſtrians againſt the king of Pruſſia: he refuſed, though at the riſk of being put under the ban of the empire, and continued faithful to the engagements which he had entered into with England. In 1759 the count obtained the command of the whole artillery of the allied army; took a conſiderable ſhare in the battle of Todenhauſen, and the ſucceſs of the day was in a great meaſure owing to the artillery of which he had the command. He was in the ſame year ſucceſsfully engaged in the ſieges of Marpurg and Munſter. On his return home, in 1760, he formed an artificial iſland in the Steinheeder lake, which is a mile in length, and half a mile broad, and being ſurrounded by moraſſes, is without the reach of cannon. Here he conſtructed a fortreſs, which was conſidered as impregnable, and it contains, beſides the uſual apartments, a chapel, and a library furniſhed with the beſt books on engineering, a collection of models, another of natural curioſities, and lodgings for the officers, with a ſchool for engineers, and an obſervatory. In 1761, when the war broke out between Spain and Portugal, count Lippe was appointed by his Britannic majeſty as commander-in-chief of the Britiſh troops ſent to the aſſiſtance of the latter. He was afterwards entruſted with the command of both armies, and in 1762 proceeded, by way of England, to Portugal. Soon after his arrival, the king ordered the ſum of forty thouſand cruſadoes to be paid him for his eſtabliſhment, but he immediately diſtributed one-half of the money among the ſoldiers, and ſent back the remainder, except what was ſufficient to pay for his uniform of field-marſhal, to the king. His majeſty even offered him a penſion of 3000*l.* but this the count declined, and nothing could induce him to accept of that remuneration of his ſervices to which he was unqueſtionably entitled. By his exertions principally, Portugal was protected from the danger threatened to it by her powerful and ambitious neighbour. The king of Portugal, Joſeph I. who knew how to appreciate count Lippe's talents, employed him in a civil as well as military capacity, and, in conſequence of his advice, introduced many improvements into the political adminiſtration of the kingdom, and particularly into the financial department. His principal object was to eſtabliſh the army on a reſpectable footing, and to inſpire the ſoldiery with a more delicate ſenſe of honour. The war which he carried on with Spain was merely a defenſive one, but he effected more by it than he could by one of a contrary deſcription, as he was enabled to throw ſo many obſtacles in the way of the enemy, that their plans were rendered entirely fruitleſs. In 1763, before he left Portugal, he eſtabliſhed a ſchool of artillery, and conſtructed on the Spaniſh frontier a very ſtrong fortreſs, which, in commemoration of his name, was called Fort Lippe. At the general peace the count returned to Germany, carrying with him abundance of preſents from the kings of Portugal and England, in teſtimony of their eſteem and approbation. He now employed much of his time in the ſtudy of the military art, and in bringing his theories to the teſt of practice. As the reſult of his experience and obſervations, he wrote a treatiſe on the art of defenſive war, in ſix ſmall volumes, which is ſaid to poſſeſs much merit, but of which he had only ten copies printed. In 1767 he reviſited Portugal by the king's invitation, and completed the reform which he had begun in the Portugueſe army. In the following ſpring he returned to Germany, and ſoon after was honoured with a viſit from Frederic II. of Pruſſia. The remainder of his life he employed in promoting the proſperity of his ſtates, and the happineſs of his ſubjects. He died in 1777, in the fifty-fourth year of his age. Sublime thoughts and heroic ſentiments had been as familiar and natural to his mind as they were to the nobleſt characters of Greece and Rome. The animation of his features announced the elevation, ſagacity, penetration, kindneſs, virtue, and ſerenity of his ſoul. In his retirement he amuſed himſelf with the arts and ſciences, but his favourite ſtudies were philoſophy and ancient hiſtory. He poſſeſſed an extenſive knowledge in every department of literature, and by his travels in foreign countries he had become familiarly acquainted with the French, Engliſh, Italian and Portugueſe languages: he was an excellent draftſman, a great connoiſſeur in paintings; and excelled ſo much in muſic, that he was able to direct the concerts which were given in the evening at his reſidence. Gen. Biog.

Lippe, in *Geography*, a county of Germany, W. of the biſhopric of Paderborn, divided into ſeveral branches, which derive their names from the different towns and parts of the principality belonging to each. The country, generally mountainous, contains ſome good arable land. Its chief towns are Detmold and Lemgow, and the principal rivers are the Emmer and the Werra. It now forms a part of the kingdom of Weſtphalia.—Alſo, a town of Weſtphalia, called *Lippſtadt*, on a river of the ſame name; 14 miles W. of Paderborn. N. 51° 39′. E. long. 8° 24′.

LIPPEHNE, a town of the New Mark of Brandenburg; 26 miles N. of Cuſtrin. N. lat. 53° 4′. E. long. 15° 3′.

LIPPI Fra. Filippo, in *Biography*. Concerning the exact date when the birth of this very excellent hiſtorical painter took place, authors differ extremely. The moſt probable account fixes it about the beginning of the fifteenth century, as he was a ſcholar of, and of courſe nearly contemporary with, Maſſaccio. At the age of ſixteen, being entered a noviciate in the convent of Carmelites at Florence, where he was born, he had there an opportunity of ſeeing that extraordinary artiſt at work upon the aſtoniſhing freſcoes with which he adorned the chapel of Brancacci, in the church there; and became eager to embrace the art he ſaw capable of ſo much effect in affording gratification, inſtruction, and intereſt to the mind.

Such was his ſucceſs, and ſo did he enter into the principles and manner of his great maſter, that after the death of the latter, it was ſaid, by common conſent, that the ſoul of Maſſaccio ſtill abode with Fra. Filippo.

He forſook the habit of his convent, and devoted himſelf entirely to painting; but his ſtudies were for a time diſturbed by his being unfortunately taken, while out on a party of pleaſure, by ſome Moors, and carried priſoner to Barbary; where he remained in ſlavery 18 months. He obtained his liberty by his talents. He drew the portrait of his maſter upon a wall with ſo much ſpirit and accuracy in reſemblance, that he, being ſtruck with the ingenuity of his ſlave, and generouſly feeling compunction in confining a man of ſuch uſeful talents, gave him his freedom as a reward.

On his return home he painted ſome works for Alphonſo, king of Calabria. He employed himſelf alſo in Padua; but it was in his native city of Florence, that his principal works were performed. He was employed by Coſmo di Medici; who preſented his pictures to his friends; and one to pope Eugenius IV. He was alſo employed to adorn the palaces of the republic, the churches, and many of the houſes of the principal citizens; among whom his talents were held in high eſtimation.

The holy mode of life into which he was conducted in early years, and the fine endowments of mind which he enjoyed by nature, did not teach him the folly of vice; and he met in this world with a ſevere puniſhment, juſtly due to a guilty amour he indulged in at Spoleto; where he was employed at the cathedral to paint the chapel of the Bleſſed

Virgin. There, in his ſixty-ſeventh year, he was poiſoned by the relations of the lady whoſe favours he was ſuppoſed to enjoy. Lorenzo di Medici erected a marble tomb in the cathedral to his memory, which Angelo Politiano adorned with a Latin epitaph.

Lippi Filippo, ſon of the former, was renowned for excellent imitations of architectural ornaments. He died in 1505, at the age of 45.

Lippi Lorenzo, alſo a Florentine painter, born in 1606. He was likewiſe a great muſician and a poet. In the latter character he publiſhed "Il Malmantile racquiſtato." He died in 1664.

LIPPIA, in *Botany*, was ſo named by Houſtoun, in honour of Auguſtine Lippi, a French botaniſt, as we learn from Linnæus's *Critica Botanica*, p. 93. He is alſo mentioned by *Boehmer*, in his diſſertation *de plantis in cultorum memoriam nominatis*, as having travelled into Egypt, and as having died in Abyſſinia.—Reliq. Houſt. 6. Linn. Gen. 322. Schreb. 399. Willd. Sp. Pl. v. 3. 356. Mart. Mill. Dict. v. 3. Michaux Boreal. Amer. v. 2. 15. Jacq. Amer. 176. Juſſ. 109. Lamarck Illuſtr. t. 539. Gærtn. t. 56.—Claſs and order, *Didynamia Gymnoſpermia*. Nat. Ord. *Stellatæ*, Linn. *Vitices*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of two diſtant, acuminated, keel-ſhaped, erect, permanent leaves. *Cor.* of one petal, unequal; limb divided into four ſegments, the upper and lower ones larger, the upper one erect. *Stam.* Filaments four, ſhorter than the corolla, two of them ſhorter than the reſt; anthers ſimple. *Piſt.* Germen ſuperior, ovate, compreſſed or flattiſh; ſtyle thread-ſhaped, ſtanding between the ſtamens, and of equal length; ſtigma oblique. *Peric.* none, except the permanent calyx in which the ſeeds are enveloped. *Seeds* two, adhering together, ovate, ſomewhat bony, convex on one ſide, rather ſmooth, flat on the other ſide, or ſomewhat concave, whitiſh.

Eſſ. Ch. Calyx four-toothed, two-valved when mature. Corolla funnel-ſhaped, four-cleft. Seeds enveloped in the calyx.

1. L. *americana.* Linn. Sp. Pl. 883. Reliq. Houſt. t. 12.—Heads of flowers forming a pyramid. Leaves ovate, ſerrated.—Found by Dr. Houſtoun at Vera Cruz, and cultivated by Mr. Miller before 1733.—This is a *ſhrub* which riſes to a conſiderable height. *Stems* round, compreſſed at their joints. *Leaves* lanceolate, ovate, rugged. *Flowers* forming little oblong heads, about the ſize of a large pea

2. L. *hemiſphærica.* Linn. Sp. Pl. 883. Jacq. Amer. t. 179. f. 100.—Heads of flowers hemiſpherical. Leaves oblong, entire.—A native of South America.—*Stems* eight or ten feet high. *Branches* woody, bending down unleſs ſupported. *Leaves* oppoſite, two or three inches long, ſmooth. *Flowers* ſmall and white. The whole ſhrub is odorous and aromatic.

3. L. *hirſuta.* Linn. Suppl. 288. Willd. n. 2. (L. umbellata; Willd. n. 4. Cavan. Ic. 75. t. 174.)—Heads of flowers ovate. Leaves oblong, broad, ſerrated, downy beneath.—A native of Mexico and other parts of America.—*Stem* four-ſided, rough with white hairs. *Leaves* oppoſite, long, hairy above, downy and hoary beneath. *Flowers* ſmall.

From examining the Linnæan ſpecimen of L. *hirſuta*, ſent originally by Eſcallon, a pupil of Mutis, we are enabled to ſtate that L. *umbellata* of Willdenow and Cavanilles is not a diſtinct ſpecies. The *flowers* of that are ſaid to be of a deep yellow, and we find thoſe of *hirſuta* tinged with the ſame colour, in a dried ſtate. As the younger Linnæus ſaw it in no other condition, he appears to have gueſſed them to be white, but erroneouſly.

4. L. *cymoſa.* Willd. n. 5. Swartz. Prod. 93. Ind. Occ. v. 2. 1066. (Spirææ congener, ſpinoſa, &c. Sloan. Jam. v. 2. 30. t. 174. f. 3 and 4.)—Flowers in cymes. Leaves ovate, acute, nearly entire.—A native of woody ſavannahs, in the ſouthern parts of Jamaica, flowering in May.—*Stems* ſeveral from three to ſix feet high, about the ſize of a gooſe-quill. *Leaves* almoſt round, yellowiſh-green, ſmooth, ſcented like thoſe of Penny-Royal. *Flowers* many together, of the colour and ſomewhat reſembling thoſe of *Spiræa Theophraſti.*

L. *ovata.* Linn. Syſt. Veg. ed. 14. 574. Mant. 89, is properly referred by l'Heritier and Willdenow to *Selago.*—Michaux places *Verbena Nodiflora* of Linnæus in *Lippia*, though with doubt, and adds another ſpecies, L. *lanceolata*, which we preſume is nearly allied to *nodiflora*

LIPPIE, a corn meaſure in Scotland; four lippies being equal to one peck.

LIPPITUDO, (from *lippus*, blear-eyed.) The ſignification of this term, in *Surgery*, is rather indeterminate. Celſus attaches the ſame meaning to it as ophthalmy. Lippitude, or blearedneſs, according to Wiſeman, is a ſtate of the eyes, in which they are dimmed with rheum. We believe that, at preſent, ſurgeons generally underſtand by lippitudo a chronic inflammation of the ciliary glands, and of the edges and inſide of the eye-lids, attended with a ſecretion of viſcid matter, by which the eye-lids are glued together during ſleep, and cannot be opened in the morning without trouble, pain, and a copious emiſſion of tears. The caſe is frequently accompanied by more or leſs inflammation of the conjunctiva, and always by a weak impaired ſight. In bad caſes, the margins of the eye-lids are ſtudded with little ulcerations; the eye-laſhes fall off; and either an entropium or an ectropium taking place, the diſeaſe is rendered more complicated.

One of the beſt remedies for lippitudo is the unguentum hydrargyri nitrati, a ſmall quantity of which is to be applied once or twice every day to the edges and inner ſurfaces of the eye-lids. Care is to be taken that theſe parts are well ſmeared with the ointment, which ſhould be melted in a ſpoon, and applied by means of a camel-hair pencil. Several other ointments will anſwer the purpoſe, particularly ſuch as contain hydrargyrus nitratus ruber, tutty, Armenian bole, &c.; but that above recommended will always anſwer when others will, and very often ſucceeds when they will not. The effect of the ointment may frequently be advantageouſly promoted, by waſhing the eye ſeveral times a day with a collyrium, compoſed of roſe-water ℥viij and zincum vitriolatum, from gr. x to gr. xx, according to the ſenſibility of the organ.

Writers on ſurgery mention caſes of diſeaſe of the ciliary glands, which are ſaid to depend upon ſcrofula, a ſcorbutic habit, and the venereal diſeaſe. We cannot vouch for the accuracy of this ſtatement, but we think it certain that numerous inſtances are kept up by conſtitutional cauſes, which prevent the efficacy of local applications and ſimple methods, and often create a neceſſity for reſorting to internal as well as external treatment. In the examples alluded to, it was juſtly remarked by Mr. Warner, that the ordinary means will fail unleſs aſſiſted by proper regimen in diet, and alteratives of different kinds, ſuch as calomel, Plummer's pills, extractum cicutæ, alkaline abſorbents, decoctions of the woods prepared in lime-water, or common water, bark, vinum antimoniale, &c. Coſtiveneſs is at all times to be prevented. Warner alſo approves of applying, in certain caſes, bliſters to the head, neck, or betwixt the ſhoulders. He thought that they acted not only as ſtimulants and evacuants,

cuants, but as alteratives, by the cantharides being freely abſorbed into the circulation. He was likewiſe an advocate for iſſues. See Deſcript. of the Human Eye, and its principal Diſeaſes, by J. Warner, F.R.S. p. 13.

LIPPOMAN, Lewis, in *Biography*, a learned Italian prelate, deſcended from a noble Venetian family, flouriſhed in the ſixteenth century, but the time of his birth is not known. Being intended for the church, he purſued his ſtudies with ſo much diligence and ſucceſs, that he was conſidered one of the ableſt divines of his time: he was likewiſe diſtinguiſhed for his capacity for buſineſs. He acquired conſiderable reputation by his attendance at the council of Trent, and was fixed on by pope Julius III. as one of the three preſidents of that council. He went as nuncio into Germany, and was afterwards ſent in the ſame high capacity into Poland, by pope Paul IV. who made him his ſecretary. In Poland he was the unrelenting perſecutor of the Jews and Proteſtants; and by his zeal in defence of his own religion, he obtained, ſucceſſively, the biſhoprics of Verona, Modena, and Bergamo. As a writer he publiſhed "Catenas" of the Greek and Latin fathers, upon "Geneſis," "Exodus," and the "Firſt Ten Pſalms." He made alſo a new collection of "The Lives of the Saints," in eight vols. folio. He died in 1559, and is mentioned by De Thou as one equally illuſtrious for the purity of his principles, and the innocence of his life. Moreri.

LIPPSPRING, in *Geography*, a town of Weſtphalia, in the biſhopric of Paderborn, at the ſource of the Lippe; rendered famous by Charlemagne's obliging the Saxons to embrace Chriſtianity in this place, and holding in it three councils; four miles N. of Paderborn.

LIPRAZZO, a town of Naples, in Capitanata; 17 miles W.S.W. of Manfredonia.

LIPS, Labia, in *Anatomy*, the edge, or exterior part, of the mouth; or that muſculous extremity which ſhuts and covers the mouth, both above and below. See Deglutition and Lip.

Lips are alſo uſed to ſignify the two edges of a wound.

Lips, in *Geography*, a town and caſtle of Hungary; four miles N. of Neuſol.

LIPSE, or Lipsius, Justus, in *Biography*, a very eminent philologiſt and critic, was born at a village, near Bruſſels, in the year 1547. He ſhewed an early diſpoſition for the purſuits of literature, which was cultivated at the Jeſuits' ſchool in Cologne, whither he was ſent when he was about 12 years of age. From thence he went to Louvain, and engaged in the ſtudy of the civil law, ſtill retaining a ſtrong predilection for the belles lettres. His firſt work was entitled "Variarum Lectionum Libri Tres," which he dedicated to the cardinal Granvelle, who patronized him, and received him into his houſe at Rome, where he arrived when he was twenty years of age. He ſpent two years with the cardinal in the quality of Latin ſecretary, and employed every leiſure hour in collating MSS. in the Vatican and other libraries, and cultivating an acquaintance with the eminent ſcholars then reſiding in the metropolis. On his return to Louvain he paſſed ſome time in youthful gaieties, but becoming ſenſible of the danger of diſſipated habits, he reſolved to quit the ſcene, and viſit Vienna. In 1572 he accepted the profeſſorſhip of hiſtory at Jena, though a Lutheran univerſity: he quitted Jena in two years and went to Cologne, where he wrote his "Antiquæ Lectiones," conſiſting chiefly of emendations of Plautus; and at the ſame period began his notes upon Tacitus. After this he went to Louvain, and was created a doctor of laws: from thence he proceeded to Leyden, accepted the profeſſorſhip of hiſtory, and exchanged the Roman Catholic religion for that of Calviniſm. Here he ſpent thirteen of the moſt valuable years of his life, and obtained much reputation by the works which he publiſhed. Theſe were upon various topics, critical, hiſtorical, and philoſophical: but his commentaries upon Tacitus were particularly eſteemed by the learned. In two of his works, *viz.* "Politicorum Libri VI." and "De una Religione," he openly maintained the maxims that no ſtate ought to permit a plurality of religions, but ought to exerciſe the utmoſt ſeverity againſt all thoſe who diſſent from the church. Such ſentiments, carried to the extent in which he carried them, gave great offence to the government of this country, and he was glad to withdraw into Flanders for ſafety. There he abjured the Proteſtants, and joined the Catholics, with whom he lived the remainder of his life. He ſettled again at Louvain, and taught the belles lettres with great ſucceſs: he received liberal propoſals from various ſovereigns and other perſons of diſtinction to reſide under their protection, but preferred to continue at Louvain, where he publiſhed ſeveral works, ſome of which were not only of inferior merit, but diſplayed the weakneſs of a very ſuperſtitious mind; he did not ſcruple to give an account of the wonders and miracles performed at the ſhrines of two images of the Virgin Mary: in this he adopted every puerile and abſurd tale that he found current among the vulgar. Lipſius died at Louvain in 1606, in his fifty-ninth year. His works have been collected in ſix volumes folio, divided, according to their ſubjects, into ſacred hiſtory, Roman and foreign hiſtory, political and moral diſcuſſions, &c. He was a very able Latin ſcholar, and wrote commentaries upon Plautus, Tacitus, Valerius Maximus, Velleius Paterculus, and Seneca. Moreri. Bayle.

LIPSK, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 28 miles W.S.W. of Sluck.—Alſo, a town of Poland, in the palatinate of Sandomirz; 30 miles N. of Sandomirz.

LIPSO, an iſland in the Grecian Archipelago, about eight miles in circumference; ſix miles S.S.E. of Patmos. N. lat. 37° 24'. E. long. 26° 23'.

LIPTOTES, in *Rhetoric*, a figure, wherein, by denying the contrary of what we intend, more is ſignified than we would ſeem to expreſs. Thus in the following verſe of Virgil.

"Quid prodeſt, quod me ipſe animo non ſpernis, Amynta."

See Voſſius, Rhet. lib. iv. p. 183.

LIPYRIA, in *Ancient Medicine*, λειπυρια, a term applied to thoſe varieties of continued fever, in which a burning heat was felt in the viſcera, while the extremities and external parts were cold. It was aſcribed by Galen and Aëtius to an eryſipelatous inflammation of ſome of the abdominal or thoracic viſcera. See Galen, Comment. 2. in Prog. & Com. ad Aph. 48. lib. iv.—Aët. Tetrab. 2. lib. ii. cap. 89.—Alſo Föeſii Œconom. Hippocrates.

LIQUAMEN Pyriticum, in *Natural Hiſtory*, a name given by ſome authors to the liquid matter remaining in the pans in which the common vitriol is made; after which no more of that ſalt will ſhoot. It is otherwiſe called liquamen of vitriol.

LIQUAMUMIA, a term invented by ſome of the diſpenſatory writers, to ſignify human fat.

LIQUEFACTION, an operation, by which a ſolid body is reduced into a liquid; or the action of fire or heat on fat, and other fuſible bodies, which puts their parts into a mutual inteſtine motion.

The liquefaction of wax, &c. is performed by a moderate heat, that of ſal tartari, by the mere moiſture of the air.

All ſalts liquefy; ſand, mixed with alkalis, becomes liquefied

quefied by a reverberatory fire, in the making of glaſs. In ſpeaking of metals, inſtead of liquefaction, we ordinarily uſe the word *fuſion*.

LIQUET. See Non Liquet.

LIQUID, a body which has the property of fluidity; and, beſides that, a peculiar quality of wetting other bodies immerged in it, ariſing from ſome configuration of its particles, which diſpoſes them to adhere to the ſurfaces of bodies contiguous to them. See Fluid and Liquidity.

Liquids, *Denſity of.* See Density.

Liquid *alum*, *amber*, *confects*, *laudanum*, *meaſures*, *ſtorax*, *ſulphur*. See the reſpective ſubſtantives.

Liquid, among *Grammarians*, is a name applied to certain conſonants oppoſed to mutes.

L, *m*, *n*, and *r*, are liquids. See L, M, N, &c.

LIQUIDAMBAR, in *Botany*, from *liquidum*, fluid, and *ambar*, a fragrant ſubſtance, generally taken for ambergriſe; alluding to the aromatic liquid gum which diſtils from this tree. Linn. Gen. 499. Schreb. 649. Willd. Sp. Pl. v. 4. 475. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 365. Juſſ. 410. Lamarck Illuſtr. t. 783. Gærtn. t. 90. Michaux Boreal-Amer. v. 2. 202.—Claſs and order, *Monoecia Polyandria*. Nat. Ord. *Amentaceæ*, Linn. Juſſ.

Gen. Ch. Male flowers numerous, in a long, conical, looſe catkin. *Cal.* a common involucrum of four ovate, concave, deciduous leaves, the alternate ones ſmaller. *Cor.* none. *Stam.* Filaments numerous, very ſhort, in a maſs which is convex on one ſide, flat on the other; anthers erect, of two lobes and two cells, with four furrows.

Female flowers collected into a globe, at the baſe of the male catkin. *Cal.* an involucrum, as in the male, but double, the proper perianths being ſeveral within it, connected together, bell-ſhaped, angular, warty. *Cor.* none. *Piſt.* Germens two, ſuperior, united to the perianth and to each other; ſtyle to each ſolitary, long, awl-ſhaped; ſtigma recurved, downy. *Peric.* Capſules two, coriaceous, beaked, of one cell, opening at the inner edge. *Seeds* ſeveral, oblong, compreſſed, ſhining, with a membranous point.

Eſſ. Ch. Male, Catkin with a four-leaved involucrum. Corolla none. Stamens numerous.

Female, Catkin globoſe, with a four-leaved involucrum. Perianth of one leaf, pitcher-ſhaped, two-flowered. Corolla none. Styles two. Capſules two, ſurrounded by the perianth at their baſe, each of one cell, with many ſeeds.

1. L. *ſtyraciflua.* Maple-leaved Liquid-amber, or Sweet Gum. Linn. Sp. Pl. 1418. Duhamel Arb. v. 1. 366. n. 1. t. 139. Sm. Inſ. of Georgia, t. 48. Ehrh. Pl. Off. 129—Leaves palmate, ſerrated, acute; veins hairy at the baſe of their ramifications.—Native of ſwampy ground in moſt parts of North America, near rivulets. It is a tall, ſtraight, and handſome *tree*, with a round head of alternate, ſtalked, elegant and ſhining *leaves*, palmate like ſome kinds of maple, ſmaller than thoſe of the Plane. *Flowers* terminal; the male a ſtalked, hairy, branched, conical catkin, or rather perhaps a cluſter of globoſe flowers, nearly a finger's length; female a globular head, on a long ſimple bracteated ſtalk, ſpringing from the baſe of the former. *Fruit* ſmaller than that of the Plane, beſet in every direction with the long prominent points of the capſules. This tree is hardy in our gardens, and very ornamental, changing in autumn to various rich hues of red and orange, but does not bloſſom in Europe, at leaſt not till it is very old. The gum, which exudes from any wounds in the trunk, in the warmer parts of its native climate, is ſeldom produced here. We have once collected it from a tree in Kew garden. Its ſcent is very fragrant and agreeable, like Benzoin or Storax.

2. L. *imberbis.* Oriental Liquid-amber. (L. orientalis; Mill. Dict. ed. 8. n. 2. Platanus orientalis; Pocock's Travels, v. 2. t. 89. *Willd.*)—Leaves palmate, bluntly crenate, or wavy, obtuſe; veins naked.—Native of the Levant. Seeds were ſent to France by Peyſonel, and ſome were forwarded to Miller, who raiſed plants from them at Chelſea. Whether any of theſe trees exiſt in England at preſent we know not. Some were to be ſeen at Paris 25 years ago, and probably ſtill remain. This ſpecies differs from the former in having ſmaller *leaves*, whoſe lobes, as well as their notches, are all blunt, their margins wavy, not ſerrated, and their veins nearly or quite deſtitute of all pubeſcence at their origin.

For L. *aſplenifolium* of Linnæus, a name which he afterwards changed, much for the worſe, to *peregrinum*, ſee Comptonia.

Liquidambar, in *Gardening*, compriſes plants of the hardy deciduous tree kind, of which the ſpecies cultivated are the maple-leaved liquidambar, or ſweet gum (L. ſtyraciflua;) and the oriental liquidambar (L. imberbis.)

Method of Culture.—Theſe two plants are increaſed by ſeeds and layers. In the former mode the ſeed ſhould be ſown as ſoon as it is procured from abroad, in ſpring, in a bed of light earth, half an inch deep, when the plants will riſe ſome the ſame year and others not until the ſpring following, moderate waterings being occaſionally given, keeping them clean from weeds all ſummer, and protecting them from ſevere froſt the firſt two winters. When the plants are two years old, plant them out in ſpring, in nurſery rows, two feet aſunder, to remain three or four years, or till wanted for planting in the ſhrubbery, and other places. But ſome ſow the ſeeds in pots, or boxes, in order to move them to different ſituations as the ſeaſon requires; and when the plants do not come up the ſame year, the pots may be plunged in a hot-bed in the following ſpring, to forward their riſing.

In the latter, or layer method, the layers ſhould be made from the young ſhoots of the preceding ſummer, by ſlit-laying, when moſt of them will be rooted in the following autumn, though, in a dry poor ſoil, they are ſometimes two years before they are ſufficiently rooted for being removed to plant out.

Theſe trees have great merit for ornamenting ſhrubbery plantations, in aſſemblage with others of ſimilar growths, being handſome, ſtraight-growing trees, with fine heads, as well as adapted for planting detached as ſingle objects, in ſpacious ſhort graſs openings, in which they appear very ornamental, perfuming the air all round in the ſummer months. They ſucceed in any common ſoil and ſituation, and endure the ſevereſt cold without injury. They are uſually kept in the nurſeries for ſale.

LIQUIDATE *an Action.* See Action.

LIQUIDATION, the act of reducing and aſcertaining either ſome dubious diſputable ſum, or the reſpective pretenſions which two perſons may have to the ſame ſum.

Liquidation, the termination or winding up of accounts, ſuch as paying or receiving debts, &c.

LIQUIDITY, in *Chemiſtry*, one of the three ſtates of bodies between the ſolid and the aeriform ſtate. The liquid and elaſtic ſtates of bodies have the common denomination of fluids, hence the word fluid cannot be uſed to expreſs either of theſe ſtates particularly. Before the improvements in modern chemiſtry, the ſame explanation was applied to account for the properties of a liquid and an elaſtic fluid, under the general appellation of fluid; although bodies in each of theſe forms are differently conſtituted.

Sir Iſaac Newton and the philoſophers of his time ſuppoſed, that fluidity was occaſioned by the ſpherical form of the particles of the bodies by which they were ſuppoſed to move with facility in all directions. Since, however, the conſtitution of bodies in different ſtates is better underſtood, ſuch an hypotheſis is not neceſſary. Haüy has rendered it very probable, that the particles of bodies are of the form of their primitive cryſtals, which are flat-ſided ſolids of the ſame regular form.

When we recollect that the particles of bodies, in the moſt ſolid ſtate in which we find them, are far from touching each other, their ſpherical figure would not avail in giving them fluid properties, when they are changed into that form by the agency of heat.

Since bodies are found to expand by heat, and contract when the heat is withdrawn, it ſeems obvious, that the particles of bodies are acted upon by two forces; the one attraction, reſiding in the particles of the bodies; and the other, the repulſion of the particles of caloric for each; and which being combined with the attractive particles, give them the tendency to recede from each other, at the ſame time that the attraction is not altered.

The equilibrium, between the two forces, is kept up by the different diſtances of the particles, on which the relative volumes belonging to different temperatures depend. If we gradually raiſe a rod of tin, or any other metal, from the common temperature to its fuſing point, we firſt obſerve its progreſſive expanſion, by which we are to infer, that the coheſive force is diminiſhing in ſome ratio of the expanſion. When it has arrived at a certain temperature, the pillar of metal will loſe its form, and if it were not confined by the ſides, it would become extended into a ſheet of a thickneſs proportionate to its degree of fluidity. In other words, when the coheſion of the particles is ſo diminiſhed, as to be exceeded by the action of gravity upon the particles individually, the ſolid will aſſume the liquid form.

This hypotheſis perfectly explains all the phenomena attendant on the liquefaction of thoſe bodies which are not ſuſceptible of cryſtallization, ſuch as wax, reſin, tallow, and ſeveral other ſubſtances. Such bodies, we obſerve, firſt begin to ſoften by the partial loſs of coheſion, and gradually become more and more liquid, till the degree of the heat ſhall occaſion their decompoſition, or give them the elaſtic form.

Theſe bodies, as we ſhould expect, increaſe in volume to the point of extreme liquidity, and the ſolid maſs is of much greater ſpecific gravity than the liquid.

The claſs of bodies that are ſuſceptible of the cryſtalline form, which takes place at the point of liquidity, appears to depend upon ſome other cauſe than the mere preſence of caloric, and on that account will preſent many anomalies to the above theory. Theſe anomalies, however, are alone obvious at the point when cryſtallization is taking place. In ſome of theſe bodies, ſuch as water, we do not obſerve any medium between perfect ſolidity and almoſt perfect liquidity.

The ſolids are in general of leſs ſpecific gravity than the liquids, and conſequently float upon them. And it is obſerved, that the point of maximum denſity is at a higher temperature than the point of congelation. The greateſt denſity of water is, according to the enquiries of Dalton, at 36°, the point of congelation being at 32°. If, however, a maſs of water be cooled, while the veſſel holding it be kept at reſt, it may be reduced as low as 18°, and even 16°, without congelation, contracting in volume all the time. When, however, the veſſel is agitated by giving a tremulous motion to the table, the whole becomes inſtantly ſolid, with a certain degree of expanſion, and the temperature riſes to 32° at the ſame moment of time. It would therefore ſeem, that the contraction and expanſion by the preſence or abſence of caloric would be perfectly conſonant with the change of temperature, were it not for the interference of this myſterious law of cryſtallization.

The circumſtances under which the congelation of cryſtalline bodies takes place, clearly ſhews that ſomething more is wanting than the mere abſtraction of caloric. Salts are found to cryſtallize by ſtanding for a certain time, although the temperature and quantity of water remain the ſame. It would therefore appear, that the integrant particles require time to arrange themſelves; and that the ſalted form, as well as their regular form, is dependent on their arrangement: or that attraction of aggregation is the greateſt when the integrant particles are placed in one particular direction. And it appears, ſince the ſtrongeſt aggregation exiſts when the cryſtals are beſt formed, that the attraction cauſing ſolidity is the greateſt when the homologous ſides of the particles are parallel to one another, taking it for granted, that the particles are of the form of the primitive cryſtal.

The idea of a polarity in the particles of bodies is not new; and, from many recent facts, does not appear very gratuitous. Bodies which are magnetic or electrical, appear to be capable of arranging themſelves in ſuch order, that their poles ſhall be reverſed to each other, from the attractions of oppoſite poles. We have already a ſtriking inſtance of this electrical polarity in cryſtals of the *tourmalin*. And from ſome late experiments by Malus, it appears that even the particles of light are poſſeſſed of polarity, confirming what Newton had before conjectured.

When we apply heat to a ſolid cryſtalline body, ſuch as a piece of ice, caloric does not effect its liquefaction by removing its particles to a greater diſtance, becauſe the ice is not ſo denſe as the water; conſequently, the particles are nearer in the liquid than in the ſolid form. It would appear, in this inſtance, that the caloric had the power of leſſening, and perhaps deſtroying altogether, the polarity of the particles, an effect which is not more unlikely than that of a certain temperature deſtroying the polarity of a magnet.

When, however, the caloric is removed, the polarity may return, but this alone is not ſufficient to render the water ſolid. A certain time, with a certain degree of agitation, is neceſſary to allow the particles to aſſume their moſt favourable poſition for conſtituting the greateſt aggregation, and their greateſt regularity. We alſo ſhould infer, that during this change, in which much force is exerted, the particles occupy more ſpace, by which the expanſion is occaſioned. Similar effects take place in the congelation of moſt of the metals; and it will, doubtleſs, be found, that the ſolids of all bodies will be of leſs ſpecific gravity than their reſpective liquids, in proportion to the ſuſceptibility of cryſtallization, or, if we may be allowed the expreſſion, as the polar force of their particles.

The particles of thoſe bodies which are not ſuſceptible of cryſtallization may have little or no polarity, and hence may owe their ſolidification to the mere abſence of caloric. Their tranſition from the ſolid to the liquid form will be gradual and ſlow, and their hardneſs will be inverſely as the caloric they contain. This is not the caſe with cryſtalline bodies; their tranſition from the liquid to the ſolid form is governed by ſeveral circumſtances, and their hardneſs is not immediately in the inverſe ratio of their caloric, but more dependent upon their polar arrangement. In all probability, if it were not for this latter cauſe, the point of congelation would be much lower in the thermometrical ſcale. What we termed confuſed cryſtallization, may be a ſtate of ſolidity in which the poles of the particles are deranged.

The want of fluidity in liquids may depend upon two cauſes. In the liquids which are homogeneous, the fluidity will be more or leſs perfect, according to the temperature by which the attraction of coheſion becomes greater or leſs. In fluids which are liable to change in their properties by expoſure to the air, the want of fluidity ariſes from a ſubſtance being formed which is leſs fluid. This is the caſe with oils, both the fixed and volatile: ſuch fluids are ſaid to be tenacious. That the particles of liquids have ſtill conſiderable attraction for each other, is apparent from a fluid aſſuming the form of drops. The drops will be more or leſs ſpherical according to the fluidity, and the ſize of the globules will be inverſely as the denſity of the fluid. Hence we ſee the drops of ſulphuric acid ſmaller than thoſe of water, and the drops of mercury ſtill ſmaller.

That the attraction of the particles of liquids becomes leſs according to temperature, is obvious from the law of their expanſion. It is found that the increments of expanſion are greater than the increments of heat. Mr. Dalton is of opinion, that the expanſion of liquids is as the ſquare of the temperature, and has propoſed a new diviſion of the thermometrical ſcale agreeably to this law. The ſame law that obtains in liquids which are ſuſceptible of cryſtallization, will not probably hold good in other fluids, in which there does not appear to be any quick tranſition from ſolidity to liquidity. In order that the expanſion may be in the duplicate ratio of the temperature, it would be neceſſary that the attraction ſhould diminiſh in an equal degree with the increaſe of caloric. If the caloric, at the different points of time, be 1, 2, 3, &c. the attractions at the correſponding points ſhould be 1, $\frac{1}{2}$, $\frac{1}{3}$, &c. ſo that being inverted and multiplied into the increments of heat, they will make the increments of expanſion a ſeries of ſquares. The ſame law, according to Dalton, does not obtain in the expanſions of ſolids and elaſtic fluids. A ſeries of experiments, which would ſettle finally the relations between the increments of expanſion and temperature, in different bodies, would be of great importance.

LIQUOR. See Drink, Fluid, &c.

Liquor *Amnii*, in *Midwifery*, a clear pellucid fluid, or lymph, contained in the amnios, or inner membrane of the bag inveſting the fœtus while in the uterus. The quantity varies very much in different women, or in the ſame woman in different pregnancies. In ſome women, when at their full term of geſtation, there is not more of this fluid than three or four ounces, more commonly there are eight, ten, or twelve ounces; and in ſome rare caſes, in women of a leucophlegmatic diſpoſition, manifeſted by œdematous ſwellings of the legs, thighs, and labia pudendæ, two or three pints have been found. Its uſe appears to be to prevent the friction of the child againſt the amnios, or of the limbs of the child againſt each other, or againſt its body, which might occaſion an abraſion of the cuticle, and an unnatural coaleſcence of the parts. Its purpoſes, therefore, are the ſame as thoſe of the fluid found in the pericardium, and in all the cavities of the body in which any of the viſcera are contained. It was thought to ſerve the further purpoſe of affording aliment to the fœtus; but as children born without heads are found to be in other reſpects as perfect, as lively, ſtrong, and plump as thoſe with heads, it is evidently not neceſſary, at leaſt for that purpoſe. See Conception, and Embryo.

Liquors, *Fermented*. See Fermented *Liquors*.

Liquor, *Teſt*, among dealers in brandy. See Spirit, and Test-*liquors*.

Liquor *Aluminis Compoſitus*, in the *Materia Medica*. See Aqua *Aluminis Compoſita*.

Liquor *Ammoniæ*, or *Aqua Ammoniæ Puræ*, P. L. 1787. See Ammoniacal *Preparations*.

Liquor *Ammoniæ Acetatis*, *Aqua Ammoniæ Acetatæ*, P. L. 1787, is prepared by adding four pints of the acetic acid to two ounces of carbonate of ammonia, until bubbles of gas no longer ariſe, and then mixing. If the acid predominate, the ſolution is more grateful to the taſte, and if the acid be correctly prepared, the proportions above ſtated will be ſufficient; but where the ſtrength of the acid cannot be depended upon, it will be right to regulate them by the ceſſation of effervеſcence rather than by quantity.

Liquor *Ammoniæ Carbonatis*, *Aqua Ammoniæ*, P. L. 1787. *Spiritus Salis Ammoniaci*, P. L. 1745, is formed by diſſolving eight ounces of carbonate of ammonia in a pint of diſtilled water, and filtering the ſolution through paper. See Ammoniacal *Preparations*.

Liquor *Arſenicalis*, or *Arſenical Solution of Fowler*, *&c.* See Arsenic.

Liquor *Calcis*. See Lime-*water*.

Liquor *Cupri Ammoniati*, *Aqua Sapphirina*, P. L. 1745. See Copper.

Liquor *Ferri Alkalini*. See Iron, in the *Materia Medica*.

Liquor *of Flints*. See Flints.

Liquor *Hydrargyri Oxymuriatis* is prepared by diſſolving eight grains of the oxymuriate of mercury in fifteen fluidounces of diſtilled water, and then adding a fluid-ounce of rectified ſpirit. This ſolution is directed for the purpoſe of facilitating the adminiſtration of diviſions of the grain of this active medicine. Each fluidrachm contains $\frac{1}{16}$th of a grain of the ſalt. The ſpirit, though it aſſiſts, is not abſolutely neceſſary to the ſolution of this quantity, but it preſerves it afterwards, and prevents the vegetation of mucor, to which all ſaline ſolutions are liable.

Liquor *Mineralis Anodynus*, the name given by Hoffman to a liquor of his own invention, famous at this time in Germany, and ſuppoſed by Burggrave to be made in this manner: take oil of vitriol and Indian nitre, of each four ounces; diſtil the ſpirit gradually from this by a retort; pour two ounces of this ſpirit cautiouſly and ſucceſſively into fifteen ounces of ſpirit of wine highly rectified; diſtil this, and there comes over a very fragrant ſpirit. This is to be again diſtilled, to render it perfectly pure, adding firſt to it a ſmall quantity of oil of cloves, and a quantity of water, equal to that of the ſpirit; after this, as ſoon as the watery vapours begin to ariſe, the whole proceſs is to be ſtopped, and the ſpirit kept alone in a bottle well ſtopped. This has great virtues as an anodyne, diaphoretic, antiſeptic, and carminative. It is not certain that it is exactly the ſame with Hoffman's, that author having never publiſhed his manner of making it; but it appears the ſame to the ſmell and taſte, and has the ſame virtues.

M. Macquer ſays, that it is a mixture of very rectified ſpirit of wine, of ether, and of a little of the ſweet oil of vitriol; and that it is made by mixing an ounce of the ſpirit of wine, which riſes firſt in the diſtillation of ether, with as much of the liquor which riſes next, and which contains the ether, and afterwards by diſſolving in this mixture twelve drops of the oil which riſes after the ether has paſſed. This liquor has preciſely the ſame virtues with the ether which phyſicians now ſubſtitute for it. See Ether.

Liquor *Plumbi Acetatis*, and Liquor *Plumbi Acetatis Dilutus*. See Lead, *Extract of*.

Liquor *Potaſſæ*. See Lixivium *Saponarium*.

Liquor *Potaſſæ Subcarbonatis*. See Lixivium *Tartari*.

Liquor, or *Smoaking Spirit of Libavius*, or *Smoaking Muriat of Tin*, is a marine acid, or ſuper-oxydated muriat of tin, very concentrated, ſmoaking, and impregnated with much tin. (See Tin.) It is made by well mixing an amalgam of four parts of tin, and five parts of mercury with an equal weight of corroſive ſublimate, by triturating the whole together in a glaſs mortar, or it may be prepared by melting, in an iron ladle, 5 oz. of pure tin, adding to it five drachms of mercury, ſtirring them together, and pouring out the amalgam into a marble mortar; and then putting 20 oz. of corroſive mercurial muriat in fine powder, and mixing the whole thoroughly. This mixture is to be put into a glaſs retort, which is to be placed in a reverberatory furnace. To the retort is to be luted, with fat lute, a receiver, with a ſmall hole in it, in the ſame manner as is done for the diſtillation of concentrated mineral acids; the diſtillation is begun with a graduated and well managed fire; with an Argand lamp, or a ſand-bath. A very ſmoaking liquor paſſes into the receiver, and towards the end of the diſtillation a very thick and even concrete matter. When the operation is finiſhed, the liquor in the receiver is to be poured quickly into a cryſtal glaſs bottle, with a glaſs ſtopper. When this bottle is opened, a white, copious, thick, and poignant fume iſſues, which remains long in the air without diſappearing. (Macquer's Chem. Dict.) Prouſt gives, as the beſt proportions, 8 oz. of powder of tin (probably ſuch as is made by melting the metal and ſhaking it in a box), and 24 oz. of corroſive ſublimate, which afford 9 oz. of the ſmoaking liquor. See Ether.

Liquors, *Stygian*. See Stygian *Liquors*.

Liquors, *Clearing of*. See Clarification.

LIQUORICE, in *Botany*, *Gardening*, and the *Materia Medica*. See Glycyrrhiza.

Liquorice, in *Agriculture*, a plant of the long tap-rooted kind, often cultivated for medicinal and other uſes in the field. It grows to about four or five feet in height; its ſtalks are hard and woody; its leaves ſmall and roundiſh, ſtanding together on the two ſides of a rib, and making what botaniſts call a winged leaf. There are two ſpecies of this plant in cultivation, the *ſmooth podded* and the *prickly podded*; but they differ little, except in the ſeed-pods of the latter being armed with prickles. It is remarked that both theſe ſpecies are very hardy perennials, but that the firſt is the ſort commonly cultivated for uſe, its roots being fuller of juice, and ſweeter than the other.

It is chiefly grown for the root, which is perennial; but the ſtalks riſe in ſpring, and decay in autumn.

It is a plant which delights in a deep light ſoil, in which its roots may run down three or four feet deep, and attain a large ſize, eſpecially when permitted to ſtand three or four years. From the main root ſmaller ones generally run off horizontally; and from theſe horizontal roots, that run near the ſurface, cuttings for ſets or young plants are taken for propagation, which are generally procured at the time when the liquorice is taken up for uſe, which is in about three years after planting: but cuttings for planting may occaſionally be taken off before that period, if wanted. At the time of planting, the cuttings ſhould be divided into lengths of ſix or eight inches, each having one or more good buds or eyes, being put into the ground at any time, in open weather, from October till March; but from the middle of February till the middle of March is the beſt ſeaſon for this work: and an open ſituation is always the moſt proper for a plantation of this kind.

It has been long ſince obſerved, that this plant thrives beſt on a deep, looſe, rich mould; and if it is freſh land that has not for many years borne corn, the profit will be the greater, as the crop will be larger, and the roots of a finer quality. A rich ſandy ſoil, provided it is deep, will do well for this plant; and it muſt always be remembered, that too much moiſture is its greateſt enemy: let no one, therefore, attempt to plant it on a damp clay, leſt the whole crop be cankered.

Soils intended for liquorice ſhould be trenched two or three ſpades deep, if the depth of them will admit: then having the ſets ready, proceed to plant them by line and dibble, planting the ſets a foot diſtant in each row; putting them perpendicular into the ground, with the tops about an inch under the ſurface, and let the rows be a foot and a half aſunder; though ſome ſcarcely allow more than twelve inches between row and row. A crop of onions is alſo ſometimes ſown on the ſame ground the firſt year; which, as the roots of the onions are ſlender, and the ſtems ſpread but little at top, may be done without any detriment to the liquorice or the onions, as the former ſeldom riſes above ten or twelve inches high the firſt ſummer. The ground muſt be kept clean from weeds, during the ſummer ſeaſon, by hoeing; and if there is a crop of onions, the ſmall hoe ſhould be employed, cutting them out to four or five inches diſtance, and clearing away all ſuch as grow immediately cloſe to the liquorice plants; and when they are gathered, give the ground a thorough hoeing with a large hoe, to looſen the ſurface, and deſtroy all weeds effectually. In autumn, cut down the decayed ſtalks of the liquorice, and nothing more is neceſſary till ſpring. But in February or March, a ſlight digging ſhould be given between the rows; and, during ſpring and ſummer, all weeds be kept down by broad-hoeing; and in autumn, when the ſtalks are in a decaying ſtate, they muſt be again cut down to the ſurface of the earth, as has been juſt obſerved. The ſame management muſt be repeated every ſucceeding year; but after the firſt or ſecond year, the ſtalks of the liquorice will ſhoot ſtrongly, and ſoon cover the ground, ſo as to retard the growth of weeds in a great degree. Likewiſe every autumn, about October, when the ſtalks begin to decay, and they have been cut down to the ground, as has been adviſed before, they ſhould be wholly cleared away. It is remarked, that land cannot be made too fine, or dug too deep for liquorice; that it ſhould be at leaſt moved with the ſpade to the depth of two feet and a half; and if a little deeper, ſo much the better. And that if the land on which the liquorice ſets are to be planted is freſh, rich, and in good heart, it needs no manure for the firſt crop; but that if it has been for ſome years in tillage, the planter will do well to give it, in the ſummer time, a good dreſſing of very rotten dung, lime, and coal-aſhes, or ſoot, mixed together, ſome months before, into a compoſt: the quantity muſt be regulated by the ſtate of the land, always remembering that this plant requires a great deal of nouriſhment, and is a great impoveriſher of the ſoil, though it extracts much of its nouriſhment or food from a conſiderable depth.

But in another mode, after the ground has been properly prepared, and reduced to a very fine tilth, and laid level, ſome ſets are to be procured. Theſe are directed to be planted in rows, with dibbles armed with iron points. Some prefer rows at two feet aſunder, putting the ſets fifteen inches from each other, and three rows are planted on a ſix-feet bed; they are allowed two feet more of interval betwixt bed and bed. And in putting in ſets with a dibble, the upper end of each ſet is left juſt level with the ſurface of the ground: and when the whole ſpot of ground is planted, labourers dig up the intervals one ſpit deep, and ſpread the earth on the beds; which raiſes them about two inches above the heads of the ſets, which, by lowering the intervals, ſerves in wet ſeaſons to drain the beds. It is generally contrived to get this work done by the laſt week in September; but in favourable years, the middle of October is not too late. If the weather proves mild, no further trouble is taken with them during the winter; but if it is likely to freeze hard, the beds are covered with peas-haulm, or long dung, or ſome ſuch matters, to forward the growth of the roots in the ſpring, and protect them during the winter from the froſts. Early in the ſpring, on the firſt appearance of the weeds, the liquorice is allowed a thorough hoeing; and this is ſeveral times repeated in the dry weather of the ſummer. The winter following, they are again covered with long dung; and in the ſpring, before the roots begin to ſhoot, the ſpaces betwixt the rows on the beds are looſened with a ſpade, and the intervals dug: immediately after which, the land has a ſlight dreſſing of coal-ſoot given, which is ſown by hand: this ſhould be thick enough to make the land look black, which, by the firſt rains waſhing it in, greatly puſhes and invigorates the plants. The ſecond and third ſummers, it is only neceſſary to keep the crop clear of weeds.

About the third year after planting, the roots of the liquorice will be in a ſtate to take up; and the proper ſeaſon for this is any time from the beginning of November till February, as they ſhould neither be taken up before the ſtalks are fully decayed, nor deferred till late in the ſpring; otherwiſe the roots will be apt to ſhrink and diminiſh in weight.

Manner of taking up.—The mode of taking up the liquorice roots is by trenching the ground, beginning at one end, and opening a trench cloſe to the firſt row three ſpades deep, or to the depth of the roots; at which work, three or four ſpadeſmen are generally employed at each trench: one goes on with the top ſpit, a ſecond with the next ſpit, another with a third ſpit, and the fourth ſpadeſman commonly gets to the bottom of the roots, having a mattock to aſſiſt him occaſionally in clearing them; and, as he takes them up, throws them on the top of the ground. In this way they proceed from row to row, till the whole plantation is taken up. The ſmall ſide-roots are then trimmed off, and the beſt of them divided into lengths proper for freſh ſets, and the main roots tied in bundles for the purpoſe of ſale. It is of much conſequence to ſell them as ſoon as poſſible after they are taken up, as they are apt to loſe much of their weight by keeping.

After a crop of this root has been taken up, if it was planted on freſh land, the ſame ground is generally prepared to yield another crop; and this takes up nearly a year. In doing which, it has given it, during the winter, a thorough good dreſſing of well-rotted dung, mixed with lime: of this large quantities are laid on, ſtill having regard to the condition of the ſoil, and ploughing it well in the enſuing ſummer. In ſuch looſe ſoils as are proper for this plant, there is no occaſion to dig the land for this crop a ſecond time, the taking up the roots having ſtirred it to a ſufficient depth: this, with three or four ſummer ploughings, is as much as is neceſſary. In other reſpects, it is managed the ſame as for the preceding crop.

But if the land which has borne a crop of liquorice root was not freſh when it was planted, but had been ſome time in tillage, it is ſcarcely ever choſen to plant again with the ſame crop, without allowing ſeveral years to elapſe.

After-Culture.—In whatever way this crop is cultivated, it ſhould be kept perfectly clean by effectual hoeing in May and June; and for this reaſon it is better not to ſow onions, or any other ſmall plants, upon the land with this ſort of plants. In the liquorice huſbandry, the land ſhould likewiſe be very highly manured, and be kept well water-furrowed for the ſpring months.

In order to diſcover how much liquorice-root is waſted by being kept in dry places, a choice was made of a piece of ſingle root thirteen inches long, and full three-fourths of an inch diameter throughout, which weighed five ounces; and nine ſmall roots, thirteen inches long each, and from one-fourth to one-eighth of an inch in diameter, which weighed alſo five ounces. All theſe were put into a drawer in a dry room, the beginning of February, and were weighed the beginning of Auguſt following; when the largeſt ſingle root weighed two ounces and three quarters, and the nine ſmall roots alſo weighed full two ounces and three quarters: ſo that in ſix months theſe roots loſt almoſt half their weight. They were green and juicy when put into the drawer, and were now pretty dry and hard; but not quite ſo dry and hard as ſome of the ſame liquorice that had lain all that time in the open room. But liquorice may be kept in moiſt ſand, or laid in the earth as long, with very little waſte or loſs of weight.

As liquorice is an upright growing plant, and not apt to lodge, and its roots deſcending deep, it is very proper for the horſe-hoeing culture; in which it will probably arrive to greater perfection than in the uſual method of cultivating it, as deſcribed above.

However in Yorkſhire, where liquorice is cultivated in rich ſandy ſoils, its roots ſometimes penetrate to the depth of three or four feet, ſometimes more; but the digging of the ground all over to that depth, when it is taken up, is very expenſive. As a ſaving in this reſpect, the planters, in digging up the ground, lay it in a proper form, and replant it, making one digging ſerve for both purpoſes, which is a good method; but they ſet the plants much too cloſe: whereas, if they planted them in rows, at about four feet diſtance, and horſe-hoed it, the weeds might be deſtroyed, and the land greatly improved, eſpecially if trench-hoed; and the produce would probably be very great, after ſo full a preparation of the land. And in addition to this, it may be obſerved, that this method of cultivation is much cheaper than by hand-work, which is the uſual method.

LIQUORICE *Vetch.* See ASTRAGALUS.

LIQUORICE *Vetch, Knobbed-rooted.* See GLYCINE.

LIQUORICE, *Wild.* See ABRUS.

LIRA, or LIRE, a money of account in Italy, and alſo a ſilver coin, particularly at Milan and Venice.

LIRELLA, the diminutive of *lira*, a ridge or furrow, is uſed by Acharius for the peculiar fructification, or receptacle, of the genus *Opegrapha*. (See LICHENES.) Its colour is generally very black, though ſometimes hoary with a ſort of efflorеſcence; its form oblong, ſeſſile or immerſed, ſimple, aggregate or branched. The diſk is uſually narrow and linear, occaſionally ſomewhat dilated; the margins parallel, various in thickneſs and elevation. In Engliſh this receptacle is termed a *cleft*.

LIRIA, or LLIRIA, in *Ancient Geography*, a town of Spain, in the province of Valencia; 18 miles S. of Segorbe. This is a very ancient town, which is ſaid to have exiſted before the arrival of the Phœnicians in Spain. Under the Carthaginians it bore the name of Edera, and under the Romans of Edeta and of Laurona, when it was the capital of the country of the Edetani. There are ſome Roman monuments remaining. The town was almoſt deſtroyed during the wars of Sertorius and Pompey; but being afterwards rebuilt, it was taken by the Goths from the Romans, from the Goths by the Moors, and from them, in 1252, by

James the Conqueror, king of Aragon, who ſomewhat changed its poſition.

It is ſituated between two little hills: it has a pariſh church, two chapels of eaſe, two convents of Trinitarian and Franciſcan monks, and a population of about ſix or ſeven thouſand perſons. This town has the title of duchy. King Philip V. gave it to marſhal Berwick, and his deſcendants ſtill poſſeſs it.

LIRIODENDRUM, in *Botany*, from λιριον, or λειριον, *a lily*, and δενδρον, *a tree;* the Tulip-tree. Linn. Gen. 278. Schreb. 373. Willd. Sp. Pl. v. 2. 1254. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 329. Juſſ. 281. Lamarck Illuſtr. 491. Michaux Boreal-Amer. v. 1. 326. Gærtn. t. 178.—Claſs and order, *Polyandria Polygynia*. Nat. Ord. *Coadunatæ*, Linn. *Magnoliæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of three oblong, obtuſe, concave, ſpreading, equal, petal-like, deciduous leaves. *Cor.* bell-ſhaped, regular, of ſix oblong, obtuſe, equal petals, concave at the baſe. *Stam.* Filaments numerous, inſerted into a conical receptacle, ſhorter than the corolla, linear; anthers terminal, longer than the filaments, but ſtill ſhorter than the corolla, linear, erect, of two cells, burſting longitudinally at the outer ſide. *Piſt.* Germens numerous, diſpoſed in the form of a cone; ſtyles none; ſtigmas all crowded together, obtuſe. *Peric.* Caſes numerous, imbricated in the form of a cone, lanceolate, compreſſed, leaf-like, triangular and tumid at the baſe, each of one cell, not burſting. *Seeds* two, ovate.

Eſſ. Ch. Calyx of three leaves. Petals ſix. Anthers burſting outwardly. Seed-caſes lanceolate, imbricated in the form of a cone.

1. L. *tulipifera*. American Tulip-tree. Linn. Sp. Pl. 755. Curt. Mag. t. 275. Sm. Inſ. of Georgia, t. 102. (L. foliis angulatis truncatis; Trew Ehret, t. 10.)—Leaves lobed, abrupt.—Native of hills in moſt parts of North America, where it is vulgarly called the Poplar. This fine tree was cultivated by biſhop Compton, at Fulham, in 1688, and is now not unfrequent in England, though ſeldom flowering till an advanced age. We have however known it bloom when about 16 years old. The firſt which produced bloſſoms in this country, is ſaid to have been at the earl of Peterborough's, at Parſon's green, near Fulham. There were ſeveral, early celebrated for their ſize aud beauty, at Waltham Abbey, one of which remained lately, and perhaps ſtill flouriſhes.

Botaniſts indicate two varieties in North America, one of which is figured in Plukenet's *Phytographia*, t. 68. f. 3, and appears to differ from the common kind, repreſented in the plates we have quoted above, in having four ſlight lobes, inſtead of two great ones, at each ſide of the leaf. We have indeed obſerved the leaves to have occaſionally divided ſide-lobes, in our gardens; but as there are ſaid to be differences alſo in the colour and quality of the wood, it is much to be ſuſpected that theſe make in fact two ſpecies. In ſome trees the wood is ſaid to be yellow, ſoft and brittle; in others white, heavy, tough and hard; but no one has obſerved whether each particular variety has either form of leaf appropriated to it, which would ſettle the queſtion. The remarkable ſhape of the *leaves* of the Tulip-tree, cannot fail to ſtrike the moſt careleſs obſerver. They ſeem as if cut off with ſciſſars at the end. The elliptical obtuſe deciduous *ſtipulas*, which curiouſly enfold the young leaves, are alſo remarkable. The *flowers*, though not glaring nor ſcented, are ſingularly beautiful, reſembling a ſmall tulip, variegated with green, yellow, and orange. They appear in June and July, ſtanding ſolitary at the ends of the branches. The young bark of this tree is very aromatic.

2. L. *liliifera*. Indian Tulip-tree. Linn. Sp. Pl. 755. (Sampacca montana; Rumph. Amboin. v. 2. 204. t. 69.)—Leaves lanceolate.—Native of lofty mountains in Amboyna. Linnæus adopted this ſpecies entirely from Rumphius, led, as it ſeems, by his delineation of the fruit, which indeed ſomewhat reſembles that of a *Liriodendrum*. There is much in his deſcription, as well as figure, that accords with *Magnolia pumila*, Andr. Repoſ. t. 226. Curt. Mag. t. 977, a plant cultivated in various parts of the Eaſt Indies, as well as in China, but whoſe native country, like the ſtructure of its fruit, is really unknown. M. Correa de Serra, whoſe botanical acuteneſs is ſo well known, has pointed out to us what he conceives to be a certain criterion to diſtinguiſh a *Liriodendron* from a *Magnolia*, the cells of the anthers opening at the inner ſide in the latter, at the outer ſide in the former, which difference is confirmed by the total difference in their fruit. By this rule the *pumila* is a *Magnolia;* but reſpecting the ſuppoſed *Liriodendrum liliifera*, nothing can be gueſſed, except from its habit. We ſuſpect moreover that the *pumila*, when its fruit is known, may exhibit characters in that part, ſufficient to ſeparate it from both theſe genera; as may alſo be the caſe with *M. fuſcata*, Ait. Hort. Kew. v. 3. 331. Andr. Repoſ. t. 229. Curt. Mag. t. 1008, whoſe anthers likewiſe burſt inwardly.

What the *L. liliifera* of Loureiro, Cochinch. 346, may be, is very doubtful. He deſcribes the anthers as opening by a terminal pore.—Here then may be another diſtinct genus. The flowers are ſaid to be large, pale and ſcentleſs. Seeds imbricated in the form of a cone. He deſcribes two more, which Willdenow has adopted from the German edition of his book, as we gueſs from the miſquotation of pages. Theſe are named 1, *L. Figo*, which has a ſingled-leaved ſpathaceous calyx, and a pale flower, dotted with red; and 2, *L. Coco*, which has a three-leaved calyx, and large, very white, ſweet flower. Both are cultivated at Macao and Canton. The deſcription of their fruits is like that of the genus before us, but we much doubt their belonging really to it. Nothing, in ſhort, requires more inveſtigation than the genera of this tribe, becauſe ſcientific botaniſts had very little opportunity of ſeeing their whole fructification. We would recommend the conſideration of their anthers and ſeed-veſſels. The calyx is perhaps of leſs importance, except for ſpecific diſtinctions.

LIRIODENDRUM, in *Gardening*, compriſes a plant of the hardy deciduous ornamental kind, of which the ſpecies cultivated is the common tulip-tree, L. tulipifera.

Method of Culture.—Plants of this kind may be raiſed by ſowing the ſeeds, imported annually from America by the ſeed-dealers, in ſpring, either in the full ground, in beds of rich light earth, in a warm ſituation, placing the ſeed lengthwiſe, and covering it nearly an inch deep; or in pots or boxes, plunging them in a gentle hot-bed. When the young plants appear they ſhould be well ſcreened from the ſun, and have free air. They uſually come up the ſame ſeaſon; when in the former method water ſhould be given them in dry weather; and if the bed be arched over with hoops, to have occaſional ſhade from the mid-day ſun in ſcorching weather, it will be beneficial to the germination of the ſeeds and growth of the young plants; continuing the waterings with care occaſionally during the ſummer; and in winter, ſheltering them with mats in froſty weather to preſerve their tops, which are ſometimes a little tender the firſt year, and apt to ſuffer in this way.

When the plants are two years old, they ſhould be ſet out in ſpring in nurſery rows, two feet diſtant, and a foot aſunder in the rows; to remain a few years, till from three to ſix or eight feet high, when they may be planted where they are to remain.

But they are raiſed beſt in the open ground, where the beds are prepared of good mellow rich earth, blended with old rotten cow-dung, ſifting over the ſeeds fine turf-mould, mixed with fine ſea or pit-ſand. And they ſucceed beſt afterwards in a light ſoil, not too dry. They ſhould have their roots and branches as little pruned as poſſible.

This is a plant that grows ſo large as to become a tree o the firſt magnitude in its native ſituation, and it is generally known by the title of poplar: of late there have been great numbers raiſed from ſeeds in this country, ſo that they are become common in the nurſeries, and there are many of the trees in different parts which annually produce flowers.

At Allerton-hall, the ſeat of William Roſcoe, eſq. there is a very large tree of this kind which flowers well.

Theſe trees are highly ornamental in large plantations, among others of ſimilar growth, and have a fine effect when planted out ſingly in large openings, kept in ſhort graſs, in pleaſure grounds, or other ſituations, when they flower in any full manner.

LIRIOPE, in *Botany*, a genus dedicated by Loureiro to the mother of Narciſſus; a plant of the ſame natural family having been deſtined to commemorate her ſon. The blue colour of the preſent flower is thought alſo, by this author, to accord with the epithet *Cærula Liriope;* ſee Ovid's Metamorphoſis, lib. 3. 342.—Loureir. Cochinch. v. 1. 200.—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Spathaceæ*, Linn.

Gen. Ch. *Cal.* Sheath ovate, incurved, ſingle-flowered, ſmall, permanent, of one leaf. *Cor.* inferior, bell-ſhaped, ſpreading, divided into ſix deep, oblong, reflexed, fleſhy, equal ſegments. *Stam.* Filaments ſix, awl-ſhaped, erect, equal, ſhorter than the corolla, inſerted into the receptacle; anthers oblong, erect. *Piſt.* Germen ſuperior, roundiſh; ſtyle thick, furrowed, reflexed, as long as the ſtamens; ſtigma ſimple. *Peric.* Berry ovate, ſmooth, fleſhy, ſingle-ſeeded. *Seed* ovate.

Eſſ. Ch. Corolla in ſix deep ſegments, inferior. Sheath ovate. Berry ſingle-ſeeded.

1. L. *ſpicata.* Loureir. *Taóc tien* of the Cochinchineſe, *Mac lán* of the Chineſe.—Found commonly both in rude and cultivated ground of thoſe countries. *Roots* perennial, oblong, ſolid, brown *bulbs*, connected by creeping radicles. *Stem* none. *Leaves* numerous, crowded together, ſword-ſhaped, ſtiff, ſmooth, nearly erect, a foot long. *Flower-ſtalk* naked, round, ſlender, ſtraight, about as long as the leaves. *Flowers* ſpiked, rather ſmall, of a pale blue colour, without ſmell.

The herb before us is ſaid to have a cooling quality, and a decoction of its leaves is thought to ſtrengthen the hair. We know not what to make of Loureiro's deſcription as to referring it to any known plant.

LIRIS, in *Ancient Geography*, a river of Italy, which anciently bounded the territory of Latium towards the ſouth. This river, called alſo *Clanis* and *Glanis*, and now *Garigliano*, deſcends from the country of the Marſi towards the Apennines, or by the lake Fecinus, receives many ſtreams in its ſlow progreſs ſouthward, and at length loſes itſelf in the bay of Cajeta or Gæta. Towards its mouth, and at ſome diſtance from a grove conſecrated to the nymph Marica, the river formed extenſive marſhes. Pliny obſerves that the waters were there hot, whence Silius Italicus gives to the Liris the epithet ſulphureous. It is related, that in the year of Rome 666, Marius, purſued by the faction of Sylla, concealed himſelf in theſe marſhes, with his body under water and his head covered by roſes. The ſame place ſerved alſo as an aſylum to Varus, one of the perſons proſcribed by the triumvirate of Octavius, Antony, and Lepidus.

LIRIUM, in *Botany*, λείριον of the Greeks, is ſynonimous with *Lilium*, but Van Royen, in his *Floræ Leydenſis Prodromus*, retains it as the name of that genus, becauſe he uſes *Lilia* for the appellation of the natural order; and for this meaſure he is ſomewhere commended by Linnæus, under whoſe inſpection the book was written. *Lirium* is however become entirely obſolete.

LIS, in *Geography*, a lake of Ruſſia, in the government of Tobolſk, in the midſt of an extenſive moraſs. N. lat. 63° 5′. E. long. 99° 14′.—Alſo, a river of the ſame name, which runs into the Eniſei. N. lat. 62° 20′. E. long. 90° 14′.

Lis, *Fleur de.* See Flower-*de-Luce.* This flower was not only borne in the ancient arms of France, but adopted by our kings till the late union with Ireland. The electoral cap, as emblematic of Hanover, and the ſhamrock for Ireland, have been ſubſtituted for it.

Lis, or *Li*, an itinerary meaſure of China, equal to $1897\frac{1}{2}$ Engliſh feet: ſo that $192\frac{1}{2}$ lis meaſure a mean degree of the meridian nearly; but European miſſionaries in China have divided the degree into 200 lis, each li making 1826 Engliſh feet.

LISARA, in *Geography*, a town of European Turkey, in the province of Albania; 52 miles S.S.E. of Albaſano.

LISBON, Olisipona or *Oliſibona*, the metropolis of Portugal and royal reſidence, ſituated in the province of Eſtramadura, and forming a kind of creſcent or amphitheatre, on the right bank of the Tajo or Tagus, on ſeveral hills. The Portugueſe compute the length of the city at two leagues; and the diſtance from Belem to the eaſtern extremity is ſtated by Link to be a full German mile, or about $4\frac{1}{2}$ Engliſh miles. The breadth of the town is very various, often but ſmall, and ſometimes quite inconſiderable, not exceeding one ſtreet, but never much more than half a league. It formerly contained ſeveral magnificent churches, 50 colleges and convents, two elegant palaces, a caſtle commanding the town, and ſeveral handſome ſquares. It was ſurrounded by a ſingle wall, on which were 77 antique towers of no great ſtrength. On the river ſide it had 26 gates, and on the land ſide 17. The ſtreets were narrow and dirty, and ſome of them very ſteep. The houſes of the citizens were generally very mean, but thoſe of the nobility and gentry were built with ſtone, and exhibited an elegant appearance. Such was the ſtate of this city before it was almoſt totally deſtroyed by the earthquake, which happened Nov. 1, A. D. 1755. Since this cataſtrophe it has been built on a regular plan. The population is not eaſily aſcertained. According to the decennial cenſus in the year 1790, the 40 pariſhes of Liſbon contained 38,102 fire-places or hearths; theſe include the ſuburbs of Junqueira and Alcantara, but not the villages of Belem and Campo-Grande, though theſe, particularly the firſt, are connected with the town, being within the boundary of Liſbon. Including Belem, a market town which completely joins Junqueira, the population may be eſtimated, according to Link, at above 300,000, excluſive of the military. Liſbon is quite open on all ſides, having neither walls nor gates, nor even any fortifications, except a ſmall caſtle in the middle of the town, and a number of batteries or ſmall forts on the river. The ground on which the city ſtands is very hilly, and, according to the Portugueſe writers, is ſituated,

ated, like ancient Rome, on ſeven hills, but it may be more properly regarded as ſtanding on three hills. The firſt begins at the bridge of Alcantara, forming the proper weſtern limit of the town, and extending to St. Benedict's ſtreet. This hill is the higheſt, and much celebrated for the ſalubrity of its air. At the weſtern extremity it is but little cultivated, but farther to the eaſtward up to its ſummit, forming in that direction a plain, on which ſtands the new monaſtery. In many parts it is ſo ſteep, that it is laborious to walk along the ſtreets, and even the lower ſtreet, which runs along the river, has conſiderable declivities, and is much incommoded by torrents occaſioned by heavy falls of rain. In this part many handſome houſes are erected, intermixed with thoſe of a meaner ſort, in ſtreets that are irregular, ill paved, and often narrow. Among theſe ſcattered houſes are gardens and even corn-fields. On this hill the late queen built a church and convent, to which ſhe was much attached. The church is handſome, but conſtructed in a bad taſte, and overloaded with ornaments. Not far from this church is the Proteſtant burial ground, which is planted with cypreſſes and Judas trees (cercis ſiliquaſtrum). Beyond the houſes is a pleaſant plain, called Campo de Ourique, ſeparated from the neighbouring hills by deep vallies, and uſed as a promenade by the lower and middling claſſes. The ſecond hill is a continuation of the firſt, from which it is ſeparated by a valley of no great depth; it extends from St. Benedict-ſtreet to the valley in which are three new ſtreets built by Pombal. At the foot of the eaſtern ſide of this hill the earthquake did great damage, of which traces remain, and thus made way for the erection of ſeveral handſome houſes. On this eaſtern declivity is the opera-houſe. Above the public promenade this hill riſes to a conſiderable height, and is very ſteep towards the next valley. This eminence affords a very fine view; in the valley beneath appears the beſt part of the town; to the left are olive-gardens interſperſed with many houſes, monaſteries, and churches; oppoſite is the high ſteep hill on which the caſtle ſtands; to the left the Tagus covered with ſhips. This hill is ſucceeded by an even valley of conſiderable length and breadth, which forms the broadeſt part of the town, which was entirely rebuilt after the earthquake of 1755. On the bank of the river is a handſome ſquare, formerly the terrace or parade of the royal palace, 610 feet by 550. The quay, and the groups of people where the ſhips and boats are landing and taking in their cargoes, excite attention. The eaſt ſide is formed by a large building with an arcade, terminating in a pavilion, which is uſed as an exchange. Oppoſite to it is a ſimilar building without a pavilion. In the centre of this ſquare, the avenues of which are unfiniſhed, is an equeſtrian ſtatue of Don Joſeph in bronze, on a pedeſtal of ſtone adorned with various ſymbols. The three principal ſtreets rebuilt ſince the earthquake, are formed by large buildings of conſiderable elevation and good appearance. The line that divides Eaſt and Weſt Liſbon, which is an eccleſiaſtical diſtinction (the former belonging to the biſhop of Liſbon and the latter to the patriarchate) paſſes through this part of the town. Near this ſpot is the great palace of the Inquiſition. Another ſmall ſquare not far diſtant is uſed as a promenade, and forms a garden, with ſeveral avenues of various kinds of trees and hedges. Behind this garden are the play-houſe and the ſquare uſed for bull-fights: and at a ſmall diſtance are market places. The third hill begins with an eminence, on which is the caſtle of Liſbon, from which it continues, with ſome interruption of plains, to the eaſtern extremity of the town. The caſtle is a ſmall fort. This part of the town conſiſts of narrow, irregular, ill-paved ſtreets, in which occur a few neat houſes. The buildings are conſtructed on bad models; and even among the churches there is not one particularly diſtinguiſhed, and a conſtant noiſe of little bells and bad chimes renders them ſtill more unpleaſant. The patriarchal church is famous for the royal ſepulchres which it contains. This was conſtructed in the year 1706 by pope Clement XI., who granted to it a chapter. The patriarch has been generally a cardinal, and its revenue is computed at 114,000*l.* Liſbon was erected into a biſhopric in the 5th century, and when it was retaken from the Moors by Don Alphonſo, the biſhopric was re-eſtabliſhed by pope Eugenius III.; and in the year 1390 it was erected into an archbiſhopric. The cathedral is a Gothic edifice, dedicated to St. Vincent, who is ſaid to have ſuffered martyrdom on the cape which bears the name, and it is richly ornamented. The royal palace, which fronts the Tagus, is a large and magnificent edifice, and contains a library collected at a vaſt expence by John V. There are ſome other public buildings, which are conſtructed in a magnificent ſtyle. Along the river to the E. of Liſbon there is a ſucceſſion of ſmall houſes and villages. To the W. Belem ſo nearly joins Liſbon, that their reſpective boundaries are not eaſily diſtinguiſhed: and the ſuburb of Alcantara is only ſeparated by a bridge over a ſmall brook which here falls into the Tagus. This ſuburb is only ſeparated by an artificial boundary from that of Junqueira, as the latter is from Belem, which is a conſiderable market-town, where many perſons of property and tradeſpeople of the higher claſſes have houſes. Formerly the royal family reſided here, but the caſtle being burnt they removed to Quelus. (See BELEM.) Beſides the church of the monaſtery of Hieronymites, which is in a Gothic but grand ſtyle, there are in Belem two new built and very handſome churches. Near to one of theſe are the botanic garden and muſeum, and a royal garden with a menagerie and ſeveral aviaries. Beyond Belem is a park of conſiderable ſize belonging to the prince, in which are olive-trees and broom; and the chace on the N. of the river is appropriated to the prince, but that on the S. is for the uſe of the public. To the N.W. appear the mountains of Cintra, which lie N.E. and S.W. The Tagus waſhes the foundations of the houſes throughout Liſbon; being towards the eaſtern part about two or three leagues broad; to the W. it becomes narrower, and as far as its mouth it is only about a league broad. The river is often covered with ſhips, and large men of war may lie oppoſite to the town. The ſcene is intereſting; and the market-town called Almada, with its church on the ſummit of the hill, and the Engliſh hoſpital at the foot of it, enlivens the picture. The ſide of Liſbon towards the country conſiſts entirely of hills, from which are ſeen only the higheſt edifices of the town, and the traveller arrives ſuddenly in the city before he is aware of it. The adjacent country, particularly on the N. and E. ſides, to a conſiderable diſtance, is covered with large gardens ſurrounded with high walls. Theſe gardens are called in Portugueſe "quintas," and they generally contain plantations of orange and olive-trees, and ſometimes corn-fields and even vineyards. Beyond the weſtern part of Liſbon the country preſents naked and rocky hills; but ſome of theſe are luxuriantly fertile. The hills, indeed, form the meadows of Liſbon. The ſoil round the city conſiſts of lime-ſtone and baſalt. Cloſe to the N. ſide of the town is the famous aqueduct, conſtructed of a kind of white marble, and completed in 1738. It ſerves to convey water from ſeveral ſprings ſituated at a diſtance of three leagues, near the village of Bellas, being in ſome parts conducted under ground. Near the town it paſſes over a deep valley, and reſts on ſeveral bold arches, the largeſt of which is 230 feet 10 inches French high, and 107 feet eight inches broad. Its pointed arches ſeem changed, when viewed from beneath it, into majeſtic vaults that re-echo every ſound. The whole length of the aqueduct is 2400 feet. In the middle is a covered arch-way of ſeven or eight feet, where the water flows on each ſide through a tunnel of ſtone. Without this arched way and on each ſide is a path, where two perſons can walk abreaſt, with a parapet. The water enters the town at a place called da Amoreira, when it divides into ſeveral other aqueducts, and ſupplies the fountains, which, though formed in a bad taſte, are ornamental. Here the gallegos draw water in ſmall barrels, and cry it about the ſtreets. The water is very good, containing a portion of oxygenated calcareous earth; its ſources being in lime-ſtone hills. The trees that grow on the N. ſide of Liſbon are chiefly olive and orange trees. The latter are propagated by ſeed and afterwards grafted. In December and January the oranges begin to turn red, and at the end of January and in February, before they are ripe and ſweet, they are gathered for exportation. Toward the end of March and in April they are very good, but delicate perſons will not eat them till the beginning of May; at which time they begin to be perfectly ſweet and well-flavoured. One tree frequently bears 1500 oranges, and ſometimes 2000, and rarely 2500. The climate of Liſbon is reckoned very ſalubrious. A heat equal to 96° Fahr. is not uncommon in Portugal. The medial heat is generally about 60°. From Midſummer-day to the middle of September rain is very uncommon; in November and December heavy rains with frequent ſtorms occur. Days of perpetual ſilent rain are very rare; for in general it comes down in torrents. In January cold clear weather often prevails, but becomes milder in February, which is generally a very pleaſant month. The days of fair weather amount to 200 in the year, and thoſe of ſettled rain ſeldom exceed 80. In this city grates for fire are almoſt unknown. Ventilation and coolneſs are chiefly conſulted; and in winter a warm cloak ſupplies the want of a fire. In the vicinity of Liſbon the harveſt is in May, and the corn is thraſhed as it is with us; but in ſome parts it is trodden out by horſes or oxen, for which purpoſe a floor is made in the fields. The Portugueſe live chiefly on meat and fiſh, but are not fond of vegetables. In Liſbon the bread is generally bad. It is uſually made of wheat flour, ſometimes of maize, and never of rye. Potatoes are not cultivated, but imported from England and Ireland. Both the rich and poor conſume great quantities of bacalhao, of which the Engliſh export thither to the value of a million and a quarter of dollars. The Sardinha, or pilchard, is alſo the food and comfort of the poor. The fruits moſt common are oranges and grapes. In the vicinity of Liſbon is a ſmall vineyard, that of Carcavella, or Carcavelos, yielding a peculiar grape, which gives name to the Liſbon wine or to Carcavella; a wine that is ſaid to be generally fabricated in London. The badneſs of the police ſtrikes every foreigner on entering Liſbon. The filth is ſuffered to lie in heaps in the ſtreets, unleſs it ſhould be waſhed away by the rains. The ſtreets are rendered ſtill more inconvenient by want of light; a hoſt of dogs, without maſters, and preying on the public, wander about like hungry wolves; and, ſtill worſe than theſe, an army of banditti. The ſociety of Liſbon is dull and melancholy, eſpecially when compared with that of large Spaniſh cities. The inhabitants neither walk nor ride for mere amuſement; there is little luxury, nor are there any fine equipages. Many ſervants are kept by the higher families, but they are poorly clad and ill fed. One of the principal amuſements of the rich is the Italian opera, which is ſupported by private individuals. The play-houſe is little viſited by perſons of condition; here no women perform; and the players are frequently artiſans. The place uſed for bull-fights is a large quadrangular edifice, ſurrounded with wooden baluſtrades and benches. In ſummer there are bull-fights almoſt every Sunday, and from twelve to fifteen beaſts are killed in an afternoon: in winter this amuſement entirely ceaſes. As to the religion of the city, Link ſays, that people go to maſs becauſe they have no other walk, and that they love the ceremonies of religion as a paſtime, and follow proceſſions as they would go to an opera. Liſbon is by no means deſtitute of literary inſtitutions. The firſt and moſt important is the Academy of Sciences. (See ACADEMY.) The Geographical Academy, principally pertaining to the geography of Portugal, was inſtituted in January, 1799. Liſbon has alſo public libraries; and it has alſo ſome muſeums, and public hoſpitals.

The harbour of Liſbon is ſpacious and deep, and by the Phœnicians, who firſt traded hither, was denominated "Oliſippo," *i. e.* the Agreeable bay, whence, as ſome have ſaid, was formed the appellation of Liſbon. Others have fabulouſly aſcribed the foundation of this city to Ulyſſes, and hence derived its ancient name Ulyſſippo. The entrance of this port is difficult and dangerous, and requires the aſſiſtance of a pilot. The trade of Liſbon is extenſive; and many foreign merchants, Catholic and Proteſtant, reſide here, as it is the grand mart of all commodities brought from Brazil and other colonies belonging to the Portugueſe. N. lat. 38° 42′ 58″. W. long. 9° 4′ 40″.

Operas at the court of Liſbon, before the earthquake in 1755, uſed to be the moſt ſplendid and beſt performed in Europe. See PEREZ, GIZZIELLO, and GUADAGNI.

Liſbon and the whole of Portugal keep accounts in rees, or reas, 1000 of which make a milree. The cruſado of exchange, or old cruſado, is 400 rees, and the new cruſado 480 rees; the teſtoon 100; the vintin, or vintim, 20 rees. Hence it appears that the milree is = $2\frac{1}{2}$ old cruſados = $2\frac{1}{12}$ new ditto = 10 teſtoons = 50 vintins.

The coins of Portugal are gold pieces, coined before 1722, which are now 20 *per cent.* higher than their original value; ſo that the old dobras, coined at 20,000 rees, are worth 24,000; the Liſbonnines, or moidores, coined at 4000 rees, are worth 4800, and the halves and quarters are in proportion; but there are few of theſe coins in circulation. The gold coins, ſtruck ſince 1722, are the dobra = 12,800 rees, the meia dobra or Joaneſe = 6400 rees, the half Joaneſe = 3200 rees, the dezeſeis teſtoon = 1600, the quartinho = 1200, the oito teſtoon = 800, the old cruſado = 400 (now ſcarce), and the new cruſado = 480 rees. The ſilver coins are the new cruſado = 480 rees, halves, quarters, and eighths, or pieces of 240, 120, and 60 rees, the teſtoons of 100, and halves of 50, and vintins of 20 rees. The copper pieces are of 10, 5, 3, and $1\frac{1}{2}$ rees.

The gold piece of 6400 rees is worth 35*s.* 11*d.* ſterling. The old cruſado is worth 2*s.* 3*d*, and the milree, value in gold, is worth $67\frac{1}{4}$*d.* ſterling. The new ſilver cruſado is worth about 2*s.* 9*d.* ſterling, and the milree, valued in ſilver, is worth $68\frac{3}{4}$*d.* ſterling. Gold is to ſilver as 16 to 1.

The commercial weights are the quintal = 4 arrobas, the arroba = 32lb., the pound or arrate = 2 marks, or 16 ounces, the ounce = 8 outavas; $13\frac{1}{2}$ quintals = a ton. The pound of Liſbon is = 9552 Dutch aſes, or $7084\frac{3}{4}$ grains Engliſh troy weight; ſo that 83lb. of Liſbon = 84lb. avoirdupoiſe weight.

The meaſure for corn, ſalt, and other dry commodities, called moyo, is = 15 fanegas; the fanega = 4 alquieres = 8 meyos = 16 quartos = 32 outavas = 64 mequias. The alquiere meaſures 675 French or 817 Engliſh cubic inches; ſo that 21 alquieres are nearly = 1 Engliſh quarter, or 50 alquieres = 19 Engliſh buſhels. For liquid meaſure, the tonelada of Liſbon is = 2 pipas, the pipa = 26 almudes = 312 canadas = 1248 quartillos. The baril is = 18 almudes. The ſtandard gauge, at the cuſtom-houſe of London, of a pipe of Liſbon is 140 gallons = 31 almudes, and the almude is $4\frac{1}{2}$ Engliſh gallons nearly. The long meaſures of Liſbon are the vara = 5 palmos, and the covado = 3; the palmo = 8 inches of Liſbon, or $8\frac{1}{2}$ Engliſh inches; the covado is = $26\frac{1}{3}$ Engliſh inches; the Liſbon foot is = half a covado, or $13\frac{1}{2}$ Engliſh inches; and 9 feet of Liſbon = 10 Engliſh feet. In the freight of ſhips, 4 cheſts of ſugar, 4 pipes of oil, 4000lb. of tobacco, and 3000lb. of ſumac, are reckoned for 1 laſt. Kelly's Un. Cambiſt. See EXCHANGE.

LISBON, a town of America, in New London county, Connecticut, lately a part of Norwich; containing two pariſh churches, and 1168 inhabitants.

LISBURN, a poſt and borough town of Ireland, in the county of Antrim, and province of Ulſter, now the ſecond in the county for ſize and population; but in the reign of Elizabeth only a ſmall village, called Liſnegarvey. It lies about ſeven miles S. of Belfaſt, on the river Lagan, which ſeparates it from the county of Down. In the reign of James I. ſir Fulk Conway obtained a grant of it, and ſettled ſome Engliſh and Welſh families there. In 1641 a victory was obtained by ſir George Rawdon over the rebels under ſir Phelim O'Neil and others, little more than a month after the breaking out of the rebellion. In 1662 the church of Liſburn was erected into a cathedral for the united dioceſes of Down and Connor, and the inhabitants had the privilege granted of ſending two burgeſſes to parliament, although not a corporate body. Theſe privileges were given on account of their loyalty to Charles I. and II. In 1699 a patent was granted to ſome French refugees for eſtabliſhing a manufacture of linen in the town, to which circumſtance it chiefly owes its proſperity. The virtuous conduct and civilized manners of theſe good people were of great advantage to it, and their ſkill and induſtry ſet an example to thoſe who were concerned in the ſame buſineſs as they were, which ſoon had the effect of raiſing the quality of their manufacture to a degree of excellence unknown till then; and the linens and cambricks made in the neighbourhood and ſold in Liſburn market, have until this day kept up their ſuperior character. Though the vicinity of Liſburn to Belfaſt prevents it from being a place of much trade, there is a great deal of buſineſs done in it, in various ways. On market-days it is much frequented from the quantity of linen and other things brought to it, and it is well known as the firſt place to meet with oats of the beſt quality for ſeed. A few years ago a fine ſpire of cut ſtone was built to the church; and lately a ſteeple and cupola on the market-houſe. The houſes of worſhip are, a ſpacious church, a Preſbyterian meeting-houſe, a Quaker's meeting-houſe, a handſome Catholic chapel, and a Methodiſt chapel. There are alſo ſome good charitable inſtitutions. The number of houſes is 800, which at $6\frac{1}{2}$ gives a population of 5212. It is ſaid by Carliſle to be noted for the neatneſs of its buildings and the urbanity of its inhabitants. It ſends one member to parliament, and is 73 miles N. by E. from Dublin. Dubourdieu's Statiſtical Account of Antrim.

LISBURN, *Cape*, a cape on the W. coaſt of North America. N. lat. 69° 6′. W. long. 165°.—Alſo, a cape on the iſland of Spiritu Santo, one of the New Hebrides. S. lat. 15° 40′ 45″. E. long. 166° 57′.

LISCA-BIANCA, one of the ſmaller Lipari iſlands, near Baſiluzzo. This iſland, as well as Bottero and Dattolo, in its vicinity, is rather a rock, abounding in cruſts of ſulphate of alumine, and for the moſt part formed of lavas whitened, and ſo decompoſed that they are eaſily reducible to powder.

LISCHITZ, a town of Bohemia, in the circle of Czaſlau; 8 miles N. of Czaſlau.

LISCIANO, a town of Naples, in the province of Otranto; 8 miles S.E. of Tarento.

LISIANTHUS, in *Botany*, from λις, *ſmooth*, and ανθος, *a flower*, in contradiſtinction, as one would ſuppoſe, to certain other flowers, nearly allied in many reſpects to this, but remarkable for ſome ſort of fringe or haírineſs, as *Menyanthes*. Yet Browne, who gave the name, does not advert to this idea; and by a ſlip of the pen he quotes Burmann as being the firſt author of it, in his *Theſaurus Zeylanicus*, 145. t. 67; whereas the plant there exhibited is called *Lyſimachia*, and is *Chironia trinervia* of Linnæus!—Browne Jam. 157. Linn. Mant. 6. Suppl. 135. Schreb. 111. Willd. Sp. Pl. v. 1. 826. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 318. Juſſ. 142. Lamarck Illuſtr. t. 107.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Gentianæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, divided, more or leſs deeply, into five, lanceolate or roundiſh, erect, permanent ſegments, membranous at the edge. *Cor.* of one petal, funnel-ſhaped; tube longer than the calyx, ſwelling upwards, contracted juſt above the baſe within the calyx; limb in five deep, lanceolate or roundiſh, recurved ſegments, much ſhorter than the tube. *Stam.* Filaments five, thread-ſhaped, ſmooth, inſerted into the tube, juſt above its contraction, generally ſhorter than the limb; anthers ovate, two-lobed, incumbent. *Piſt.* Germen ſuperior, ovate-oblong, pointed; ſtyle thread-ſhaped, the length of the ſtamens, permanent, finally twiſted; ſtigma compreſſed, of two parallel plates. *Peric.* Capſule ovate-oblong, pointed, of two incomplete cells and two valves, the partitions formed of the inflexed margins of the valves. *Seeds* numerous, minute.

Eſſ. Ch. Corolla funnel-ſhaped, inflated; its ſegments recurved. Stigma of two plates. Capſule oblong, imperfectly two-celled; partitions from the inflexed margins of the valves. Seeds numerous.

Fifteen ſpecies of this elegant genus, little known in England, are collected by Willdenow, of which *glaber* and *frigidus* are one and the ſame. Whether the reſt all truly conſtitute one genus, may perhaps be doubted. The carinated calyx, ſuppoſed an eſſential mark, in thoſe of Browne, is not found in thoſe of Aublet, the ſegments of whoſe calyx moreover are rounded, and their corolla ſomewhat irregular and curved. Theſe more accord with *L. glaber* of Linnæus, and very correctly with his *chelonoides* found in the ſame neighbourhood.

The following examples will enable the reader to judge of the habit and leading characters of theſe different ſets of ſpecies.

L. *longifolius*. Linn. Mant. 43. Browne Jam. 157. t. 9. f. 1.—Calyx taper-pointed, keeled. Leaves lanceolate, acute. Branches round, ſomewhat downy.—Native of the mountains of Jamaica, in a dry ſandy ſoil. It forms a humble *ſhrub*, with round, oppoſite, more or leſs downy, level-topped, leafy branches. *Leaves* oppoſite, on ſhort footſtalks connected by a very ſhort, annular, intrafoliaceous *ſtipula*; their form is variable, ovate-oblong or lanceolate, acute, entire; the ſurface ſmooth, or finely downy. *Flowers* on ſhort, terminal, downy ſtalks, ſolitary, or two or three together, about an inch and a half long, of a pale delicate yellow, very elegant. Their *calyx* and *corolla* are very ſharply pointed; the former ſtrongly keeled or winged, as in many plants of the Gentian family; the *ſtigma* ſhort and almoſt capitate, yet of two parallel lobes.

This ſpecies is ſaid to bloſſom in the ſtove at Kew in June and July. Little or no bitterneſs is perceptible in the dried ſpecimen.

L. *cordifolius*. Linn. Mant. 43. Browne t. 9. f. 2, is probably but a mere variety, having ſhorter, and perfectly heart-ſhaped *leaves*, which, in our ſpecimen from Browne, are rather more downy, as well as the branches.

L. *latifolius*. Swartz. Ind. Occ. v. 1. 348. never ſeen by us, is not by his account very clearly diſtinguiſhed from theſe; for *longifolius* certainly has, by no means, "very long flower-ſtalks, widely ſpreading at their diviſions," which he attributes to it, but rather ſtalks "ſimply three-forked, ſcarcely longer than the leaves," ſuch as he deſcribes in his *latifolius*.

L. *glaucifolius*. Jacq. Coll. v. 1. 64. Ic. Rar. t. 33.—Calyx taper-pointed, as long as the tube. Leaves elliptic-oblong, ſeſſile, glaucous, ſmooth. Stem round.—This ſeems to agree ſufficiently in genus with the above, though its calyx appears not to be keeled. The *root* is perennial. *Stems* herbaceous, annual, ſlender, nearly ſimple. *Flowers* purpliſh-blue, on very long ſimple ſtalks. It bloſſomed with Jacquin in the ſtove, from July to September, but he knew not its native country.

L. *alatus*. Aubl. Guian. v. 1. 204. t. 80.—Leaves elliptic-oblong, tapering at each end, ſmooth. Stem ſquare, winged. Segments of the calyx rounded. Corolla declining.—Gathered by Aublet in cultivated as well as waſte ground in Guiana and Cayenne. One of his ſpecimens before us has the habit of a *Chelone*. Its *calyx* is blunt and rounded. *Corolla* declining, as well as the *ſtamens* and *ſtyle*, and ſomewhat irregular. The plant is ſaid to be bitter, and its qualities deobſtruent.

L. *chelonoides*. Linn. Suppl. 134.—Leaves oblong, ſlightly confluent at the baſe, ſmooth. Stem round, without wings. Branches of the panicle racemoſe. Calyx rounded.—Sent to Linnæus from Surinam, and marked No. 141. in the *Plantæ Surinamenſes*. It is ſo like a *Chelone* or *Pentſtemon*, that Linnæus actually took it for ſuch. His ſon afterwards referred it to *Liſianthus*, miſtaking it for the above ſpecies of Aublet, from which it differs in the round *ſtem*, deſtitute of wings; more elongated and racemoſe flowering-branches; and nearly ſtraight regular *corolla*.

L. *glaber*. Linn. Suppl. 134. Sm. Ic. ex Herb. Linn. t. 29. (L. frigidus; Swartz. Ind. Occ. v. 1. 352.)—Smooth. Leaves ovate, ſtalked, acute. Flowers ſomewhat corymboſe. Stem ſquare below.—Native of South America and Jamaica. A large and handſome herbaceous plant, with yellow *flowers*, whoſe *corolla* is regular and dilated. The ſegments of the *calyx* are indeed more rounded and obtuſe in the Jamaica ſpecimens than in thoſe of Mutis, but we cannot think that difference eſſential, every other part being ſo alike in both. The lower portion of the *ſtem* is wanting in Mutis's ſpecimen, which cauſed that part to be deſcribed as round, the branches being ſo, as well as in Swartz's.

L. *exſertus*. Swartz. Ind. Occ. v. 1. 346.—Leaves ovato-lanceolate, on longiſh ſtalks. Calyx taper-pointed. Stamens and ſtyle much longer than the corolla.—Native of the cloud-capped ſummits of the Blue Mountains of Jamaica. *Swartz*. It is ſaid to have been alive at Kew, but not to have flowered. The *ſtem* is ſhrubby. *Leaves* numerous, elliptic-lanceolate, tapering at each end, ſmooth, on ſlender footſtalks from half an inch to an inch long. *Flowers* rather ſmall, in three-forked compound panicles; remarkable for the very long, ſlender, projecting organs of fructification. If this ſpecies be carefully conſidered, it will perhaps be found to conciliate, in ſome meaſure, the differences between the diſcordant ones above deſcribed. Its *calyx* agrees moſt with the former, though neither keeled nor winged; its *corolla* with the latter; its habit is akin to both; its *ſtamens* peculiar to itſelf.

LISICZNIK, in *Geography*, a town of Poland, in Podolia; 28 miles W. of Kaminiec.

LISIEUX, a town of France, and principal place of a diſtrict, in the department of the Calvados, and before the revolution, the ſee of a biſhop. The place contains 10,192, and the canton 28,293 inhabitants, on a territory of 260 kiliometres, in 30 communes. N. lat. 49° 8′ 50″. E. long. 0° 13′ 32″.

LISIGNANO, a town of Iſtria; 14 miles E. S. E. of Pola.

LISKEARD, a borough and market-town in the hundred of Weſt and county of Cornwall, England, is ſituated partly on rocky hills and partly in a bottom; and through this inequality of the ground, the ſtreets have the appearance of being diſpoſed with ſtudied irregularity. The baſement ſtories of the houſes are conſequently diverſified; the foundations of ſome buildings being on a level with the chimnies of others. The church conſiſts of three ſpacious aiſles, and has a tower built moſtly of granite; the ſouth ſide of the church is ornamented with pinnacles and battlements, alſo of granite; but the greater part of the ſtructure is compoſed of ſlate-ſtone, which likewiſe conſtitutes the foundation of the town. The town-hall is ſupported on granite columns, in the ſpace between which a conſiderable market is held on Saturdays. Here are ſix annual fairs. On an eminence north of the town are the mouldering foundations of a caſtle, but every trace of its ſhape and architecture is nearly obliterated: near it is a large field, ſtill called Caſtle-park; but no fragments appear of the "Chapel of our Lady," mentioned by Browne Willis to have ſtood therein. There is, however, a houſe ſtanding at the bottom of the town, which, from its windows, gateway, and ſculptured ornaments, ſeems to have been connected with ſome religious eſtabliſhment. Liſkeard was conſtituted a free borough by Richard, brother to Henry III. by charter dated June 5, 1240. Queen Elizabeth, in the year 1580, granted a charter of incorporation, by which the civil government was veſted in a mayor, recorder, eight capital burgeſſes, and fifteen aſſiſtants, who, with the other freemen of the borough, elect two members of parliament. Liſkeard is 16 miles diſtant from Plymouth, and 237 from London: in the year 1800 the pariſh was returned to parliament as containing 507 houſes, and 2708 inhabitants.

In the pariſh of St. Cleer (to the north of Liſkeard) are various Druidical and other antiquities; particularly the Hurlers, which conſiſted, when perfect, of three contiguous circles of upright ſtones from three to five feet in height; the Cheeſe-Wring, a natural pile of rude rocks, riſing to the height of thirty-two feet; the Other Half-ſtone, which appears to have been the ſhaft of a croſs which originally ſtood upright. To theſe may be added, a cromlech of great magnitude, called Trevethey-ſtone. St. Cleer's well, of which ſome remains are ſtill extant, was in the times of ignorance and ſuperſtition eſteemed a bath of ſovereign virtue. South of Liſkeard is St. Keyne's well, which is claſſed by Carew among the natural wonders of Cornwall. Of this ſaint, and of the well, many poetical and legendary tales are extant. The ſpring is arched over, and on the mould which covers this arch five large trees are growing. Beauties of England and Wales, vol. ii.

LISLAU, a town of Bohemia, in the circle of Boleſlaw; ſix miles S. of Benatak.

LISLE, Claude de, in *Biography*, a celebrated French writer in hiſtory, was born at Lorrain in the year 1644.

He was received a member of the Jeſuits' college at Pont-à-Mouſſon, took his degrees in law, and was admitted an advocate. Conceiving, in a very ſhort time, a great diſlike to the law, he devoted himſelf to the ſtudy of hiſtory and geography. For the ſake of the ſuperior advantages to be obtained in the metropolis, he removed to Paris, and applied himſelf to the inſtructions of the moſt diſtinguiſhed profeſſors. Having obtained a large fund of knowledge on the ſubjects referred to, he commenced private lecturer, and acquired ſuch a high reputation in his profeſſion, that he could boaſt of having been maſter to the principal nobility at the French court. M. de Liſle died at Paris in 1720, in the ſeventy-ſixth year of his age. He was author of "An Hiſtorical Account of the Kingdom of Siam;" "A Genealogical and Hiſtorical Atlas, on engraved Plates;" "An Abridgment of Univerſal Hiſtory, from the Creation of the World to 1714," in 7 vols. 12mo.; and ſeveral other works, one of which was "An Introduction to Geography, with a Treatiſe on the Sphere;" publiſhed in 1740, in the name of his eldeſt ſon. Moreri.

Lisle, William de, a learned French geographer, ſon of the preceding, was born at Paris in 1675. He diſcovered at a very early age a genius for geographical ſtudies, and deſigned maps before he was nine years of age. In the year 1696 he publiſhed a map of the world, maps of the four quarters, as they are called, *viz.* Europe, Aſia, Africa, and America, a map of Italy, one of Ancient Africa, and two globes, a celeſtial and terreſtrial one. Theſe performances were not only well received, but eſtabliſhed the author's fame. In 1702 he was elected a member of the Academy of Sciences, and in 1718 he was appointed firſt geographer, with a penſion. He was about the ſame time appointed geographical tutor to the young king, Lewis XV., for whoſe uſe he drew up ſeveral works, among which was a general map of the world, and another of the retreat of the ten thouſand. He alſo gave the world "A Treatiſe on the Courſe of all the known Rivers." The reputation of M. de Liſle was now ſo great, that all authors of reſpectability who wrote on hiſtory or ſubjects connected with it, were deſirous of embelliſhing them with his maps; and many ſovereign princes endeavoured to tempt him to enter into their ſervice. The emperor, Peter the Great, paid him a viſit with the view of obtaining from him a knowledge of the extent and ſituation of his own dominions. He died in the fifty-firſt year of his age, while he was engaged in many uſeful and important works. Moreri.

Lisle, Lewis de, brother of the preceding, celebrated for his knowledge in aſtronomy, rendered ſome important ſervice to the intereſts of ſcience, by the hazardous journies and voyages which he undertook to promote them. In the year 1726 he went to Ruſſia with his brother Joſeph, who had been appointed aſtronomer to the Academy of Sciences at Peterſburg. Lewis, at this time, made excurſions beyond the utmoſt boundaries of the immenſe Ruſſian empire. He took ſeveral journies to the coaſts of the Icy ſea, to Lapland, and the government of Archangel, to determine the ſituation of the principal places by aſtronomical obſervations. He afterwards traverſed a great part of Siberia, with M. Muller and M. Gmelin, profeſſors of the academy at Peterſburg. In 1741 he proceeded alone to Kamtſchatka, and went from thence to Cape Beering, to examine the unknown northern coaſts of America, and the ſeas between them and the Atlantic continent. He died in the ſame year. On account of his great merit he obtained a ſeat in the Academy of Sciences, and was author of ſome papers in the "Memoirs" of that learned body, and of the Academy of Sciences at Peterſburg. Moreri.

Lisle, Joseph Nicholas de, younger brother of the preceding, was born at Paris in 1688. Having received a good education in the elements of learning, he attended lectures in the Mazarine college. The total eclipſe of the ſun which occurred in March 1706, led him to purſue with avidity mathematical learning, particularly in its application to aſtronomy, and he ſoon exhibited a ſurpriſing genius for invention, combination, and calculation. In 1709, he obtained leave to occupy the cupola of the Luxembourg palace for an obſervatory; he was now enabled to make a wooden quadrant, which he divided with great care, and which he found to anſwer his purpoſe in his early obſervations. Shortly after this, his father's numerous family made it neceſſary for him to endeavour to procure for himſelf the means of ſupport; and in doing this he found himſelf obliged to render his aſtronomical ſkill ſubſervient to the reveries of judicial aſtrology, for which he was not only remunerated by pecuniary preſents from the regent, marſhal de Noailles, and other great men, but had the grant of a penſion of 600 livres. This was in the year 1715, when he was deeply engaged in calculating the tables of the moon according to the theory of ſir Iſaac Newton. He had, previouſly to this, been elected a member of the Academy of Sciences, which gave new energy to his exertions, and the memoirs of that body were in a ſhort time enriched with his valuable reflections and diſſertations. He made many obſervations on the ſpots in the ſun, and was led to form from them a theory to determine the ſun's rotation on his axis. In 1720 he delivered a propoſal to the Academy for aſcertaining in France the figure of the earth, and ſome years afterwards his deſigns relative to that object were carried into execution. In 1724, M. de Liſle paid a viſit to England, obtained the notice and friendſhip of Newton and Halley, and was admitted a fellow of the Royal Society. In 1726, by the invitation of Catharine, empreſs of Ruſſia, he went to Peterſburg, to fill the poſt of aſtronomer royal in the Imperial Academy of Sciences. In this ſituation he occupied the houſe of the obſervatory built by Peter the Great, in which he ſpent nearly twenty-one years, in inceſſant labours for the improvement of aſtronomy and geography. The firſt ſeries of his obſervations were employed in aſcertaining the longitude and latitude of Peterſburg, and the refractions in that northern region. After this he devoted ſeveral years to an aſſiduous obſervation of the meridional height of all the planets, and of the fixed ſtars of the three firſt magnitudes, and publiſhed memoirs illuſtrative of the hiſtory of aſtronomy, in two vols. 4to. In the year 1740, a tranſit of Mercury was expected, which, as it would not be viſible in Europe, he was determined to travel into Aſia to obſerve. His firſt obſervations in the climate of Siberia, were on the intenſeneſs of the cold, which was greater than had ever been pointed out by a thermometer, or than it was conceived poſſible for human nature to ſuſtain. He publiſhed a memoir on this ſubject in the volume of the Tranſactions of the French Academy for 1749. When the time for obſerving the tranſit arrived, the cloudineſs of the weather totally fruſtrated the deſign of his journey. His time and labour were not however wholly loſt, as he employed himſelf in making geographical and phyſical obſervations, and in drawing up a deſcription of the country, which deſcription is inſerted in the eighteenth volume of Querlon's Hiſtory of Travels, &c. Another fruit of his expedition into the Ruſſian dominions, was an atlas of the country, firſt publiſhed in the Ruſſian language, and afterwards in the Latin. Connected with his meteorological obſervations, he conſtructed a thermometer, which was differently graduated from thoſe then in uſe: the degrees began at the heat of boiling water, and thence increaſed to 150, which was the freezing point. In the year 1747, after much ill treatment on the part of the Ruſſian government, he obtained his diſmiſſion, left Peterſburg in the month of May, and arrived in Paris in September of the ſame year. On his return he was appointed profeſſor of the mathematics at the college royal, in which ſituation he lived to render the greateſt ſervice to the intereſts of ſcience, by training up pupils worthy of ſuch a maſter, among whom was the celebrated M. de la Lande. He now fitted up and furniſhed an obſervatory, in which he continued his labours, without interruption, for ſeveral years. In the year 1748, his pupil M. Monnier took a voyage to Scotland to obſerve an annular eclipſe of the ſun, which furniſhed an opportunity for meaſuring the diameter of the moon at the time when it ſhould be entirely viſible on the ſun's diſk. On this ſubject De Liſle publiſhed a large advertiſement, which was reckoned a complete treatiſe on annular eclipſes. He afterwards entered more fully on the conſideration of the theory of eclipſes, and he communicated a part of his reſearches on the ſubject to the Academy in 1749. He was ſo expert in calculations, that he made many founded on the obſervations of Greenwich, Berlin, Scotland, and Sweden. He publiſhed "New Charts of the Diſcoveries of Admiral de Fonte, or Fuente, made in 1640, and thoſe of other navigators, Spaniſh, Portugueſe, Engliſh, Dutch, French and Ruſſian, in the Northern ſeas, with explications." This work was preſented to the public in 1750 and 1753. In the latter of theſe years he publiſhed a curious map of the world, in which he repreſented, for the benefit of aſtronomers impatiently waiting for the tranſit of Mercury over the ſun, the effect of the parallaxes of Mercury in different countries, in order to point out the proper places for making ſuch obſervations on the tranſit, as ſhould, from the difference of their reſult, furniſh a method of determining the diſtance of the ſun, in a manner ſimilar to that applied by Halley to the tranſit of Venus. Another work of this laborious and indefatigable philoſopher, publiſhed in the Tranſactions of the Academy, was on the comet of 1758, which had been firſt diſcovered by a peaſant in the neighbourhood of Dreſden, and which was viſible ſeveral months; but he was principally attentive to the one predicted by Dr. Halley, forty years before, as to make its appearance in 1759, and which was firſt ſeen in January of that year. He gave an account of his obſervations on that comet in the firſt volume of the "Mercure," for July 1759. He was afterwards aſſiduouſly engaged on the ſubject of the tranſit of Venus, which was expected in 1761, in order that he might correct the error of Halley, and thus prevent perſons from undertaking long voyages for the ſake of obſerving it, whoſe labours would have proved uſeleſs with reſpect to the object in view.

M. de Liſle had, ſome years previouſly to this, been appointed aſtronomical geographer to the marine, an office which had been eſtabliſhed many years, with the expreſs view of having a depôt, in which might be preſerved all the deſigns, plans, charts, &c. of the coaſts of France, and of the colonies and eſtabliſhments in different parts of the world, with the memoirs relating to them: to M. de Liſle's office was attached the buſineſs of collecting and arranging the plans and journals of naval captains, and to extract from them whatever might be found beneficial to the king's ſervice in this department. His majeſty now purchaſed, with a penſion for life, all M. de Liſle's rich aſtronomical and geographical collections, which were added to the MSS. in the depot. In the year 1758, our author felt ſome ſymptoms of decline, and withdrew as much as he could from public life, leaving the care of his obſervations to M. Meſſier, and obtaining from the miniſter the appointment of M. de la Lande for his coadjutor at the college royal. He went to reſide at the abbey of St. Genevieve, where he ſpent much of his time in devotional exerciſes, and devoted the greateſt part of his income to acts of benevolence and charity. In his retirement he cheriſhed his taſte for aſtronomy and geography, correſponded with men of ſcience, read new works, and even ſelected ſome of his own in MS. with a view to publication. He died on the 11th of July 1768, being in the 81ſt year of his age. As a man of ſcience his merits are very great, and in private life he was diſtinguiſhed by unaffected piety, pure morals, undeviating integrity, and moſt amiable manners. Gen. Biog.

Liſle de la Drevetiere, Lewis-Francis de, a French dramatic writer, was deſcended from a noble family, and born in the province of Dauphinè. His friends intended him for the bar, but his own inclinations were decidedly againſt the profeſſion of the law, and as his father could not ſupport him in the ſtyle which his diſſipated turn required, he was reſolved to maintain himſelf by his talents, and began to write for the Italian theatre. In 1721 he preſented for public exhibition his comedy of "Arlequin Sauvage," which was ſucceſsful, and which is even now occaſionally brought before the public. His "Timon le Miſanthrope" acquired a much larger ſhare of popularity: he publiſhed and brought on the ſtage many other pieces, chiefly of the comic caſt: and he compoſed a tragedy entitled "Danaus," and a poem entitled "Eſſai ſur l'Amour Propre;" which, with ſeveral other pieces, were collected in a ſingle volume. He died in 1756, and has been deſcribed as a haughty, taciturn, and thoughtful character.

Liſle, in *Geography*,. See **Lille**.

Liſle, a town of France, in the department of the Dordogne; 9 miles N.W. of Perigueux.—Alſo, a town of France, in the department of the Yonne; 24 miles S.E. of Auxerre.

Liſle, a poſt-town of America, in Tioga county, New York; through which paſſes a branch of the Chenengo, uniting with the Chenengo in the S.E. corner of the townſhip. It contains 660 inhabitants.

LISLENA, a town of Sweden, in the province of Upland; 16 miles S.S.W. of Upſal.

LISMORE, an iſland of the Hebrides, in the county of Argyle, Scotland. It is ſituated at the mouth of the great arm of the ſea called Loch-Linnhe, and extends about ten miles in length and two in breadth. The whole of this iſland lies on a ſtratum of excellent lime-ſtone, unfortunately rendered of little value to the inhabitants by the deficiency of fuel to burn it. Mr. Pennant ſays the derivation of its name is from *Lioſmor*, or the great garden. According to tradition, however, it was not a garden, but a deer-foreſt, and as a proof of this, multitudes of ſtags' horns of uncommon ſizes are frequently dug up in the moſſy parts of it. At preſent there is very little wood, but the ſoil being fertile, the leſſer vegetables ſhoot up with uncommon vigour. The chief productions of the ground are beans and oats. The former are moſtly applied to the purpoſes of diſtillation; and the latter go to the diſcharge of rents, ſo that the inhabitants are obliged to import large quantities of meal for their ſubſiſtence. There are a conſiderable number of cattle reared in this iſland, but they are generally of very ſmall ſtature. The author already mentioned thinks they muſt have greatly degenerated from their original growth, for he informs us that he ſaw the ſkull of an ox dug up here, which was of much larger dimenſions than any now living in Great Britain. About a hundred head of the largeſt are exported annually. The horſes bred here are extremely ſhort-lived.

They are harneſſed when only two or three years old, which practice will no doubt aſſiſt in ſhortening the period of their exiſtence. Neither foxes, hares nor rats can be found in the iſland; otters and mice however are abundant. It contains three ſmall lakes, two of which are famed for excellent trout, and the third for eels.

Liſmore was formerly the ſeat of the biſhop of Argyle, who was thence ſtyled Epiſcopus Liſmorenſis. Mr. Pennant ſays there are no remains either of the cathedral or the biſhop's palace. In the Beauties of Scotland, however, it is aſſerted, that veſtiges of both are ſtill to be ſeen, The chancel of the former is there ſtated to be uſed as the pariſh church, and the walls of the latter are ſaid to be pretty entire, and diſtant about four miles from the cathedral. Several fortified camps can yet be diſcovered in different parts of the iſland. A Daniſh fort, ſurrounded by a deep foſſe, is likewiſe in tolerable condition. The walls are now 17 feet high, having a gallery within, and round the area a ſtone ſeat, which Mr. Pennant ſuppoſes might have been intended as a general reſting place for the chieftains and their ſoldiers. The church, ſays the ſame author, in conformity with his aſſertion that there are no remains of the cathedral, "is a mean modern building." In the church-yard ſeveral old monuments are ſtill ſtanding, one of which is very remarkable, as conſiſting of nothing more than a thick log of wood. Its antiquity muſt be very great, as there is no word in the Erſe language to denote this kind of monument. On a rock are cut the radii of a dial, but the index is deſtroyed. A ſmall baſin is excavated in another rock, which was probably uſed by the Druids in ſome part of their religious ceremonies.

There is no ſpecial return of the number of inhabitants in this iſland, but they are reckoned to exceed 1100 ſouls. Pennant's Tour in Scotland. Beauties of Scotland.

Liſmore, a poſt-town of Ireland, on the river Blackwater, and in the county of Waterford. The bridge over the river is a fine erection of the duke of Devonſhire's. The ſpan of the principal arch is 190 feet. There are excellent ſalmon weirs at this place, which return a conſiderable profit. The appearance of Liſmore from the bridge is awfully ſublime and intereſting. The caſtle is ſeated upon a rock, which riſes in perpendicular ſhelves from the river to a tremendous height. The rude rocks are richly crowned with trees, whoſe verdant boughs in ſome parts embrace the placid ſtreams, and in others aſcend to ſhelter the ruined towers, and ſhade the antique windows of the fort. This venerable and extenſive caſtle, the property of the duke of Devonſhire, was built by king John, in 1185, on the ruins of the abbey of St. Carthagh. It afterwards became the epiſcopal reſidence, till Myler Megrette, biſhop of the ſee, conveyed it to ſir W. Raleigh. From ſir Walter it was purchaſed, with the reſt of his property in Ireland, by Richard Boyle, afterwards the firſt earl of Cork, and his youngeſt ſon, the celebrated and deſervedly eſteemed philoſopher Robert Boyle, was born in it. It has ſince become the property of the duke of Devonſhire, who is deſcended by the female line from the eldeſt branch of the Boyle family. In the town of Liſmore are a neat court-houſe, in which the ſeſſions are held, a ſmall priſon, and a very reſpectable inn. The church, which ſerves both as a pariſh church and as the cathedral of the biſhopric, is old, and was lately in indifferent repair; it is however, according to Dr. Beaufort, ſpacious and handſome, and will probably be thoroughly repaired. The dean of Liſmore has a peculiar juriſdiction over this, and two adjoining pariſhes. It has been already mentioned that St. Carthagh founded an abbey here. This was in the ſeventh century, and the abbey was erected into a biſhopric in 633. A number of monks repairing hither, ſeveral churches and cells were built, and theſe being uſually the ſeat of any learning that exiſted during the middle ages, a ſchool was ſoon inſtituted, which, for a long period, became the great reſort both of natives and foreigners. In 1536, this ſee was united to that of Waterford, under which an account of it will be given. Before the union, Liſmore returned two members to the houſe of commons, but this privilege has ceaſed. It is 101 Iriſh miles S.W. by S. from Dublin, and 26 N.E. from Cork. Beaufort, Robertſon, &c.

LISNAKEA, a poſt-town of Ireland, in the county of Fermanagh; 70 miles N.E. from Dublin.

LISS, a town of Holland; eight miles N. of Leyden.

LISSA, a town of Sileſia, in the principality of Breſlaw, on the Weiſtritz; ſeven miles W.N.W. of Breſlaw. N. lat. 51° 7′. E. long. 16° 50′.

Lissa, anciently *Iſſa*, (which ſee,) an iſland of the Adriatic, near the coaſt of Dalmatia, once famous for the commerce, wealth, and power of its inhabitants, is a mountainous and thinly inhabited iſland, 30 miles in circuit. In many parts the ſoil is good, but not ſufficiently cultivated. In its ancient ſtate it was in alliance with Rome, and carried on war againſt the kings of Illyrium; but with the decline of the Roman empire, it ſunk into a ſucceſſive dependence on Narenta, Leſina, and Venice. Its mountains contain marble, and are interſected by fertile vallies. It produces wine, fruits, and excellent honey. But its principal ſource of wealth is its fiſhery, particularly that of ſardines. The ruins of its capital of the ſame name appear above the harbour, near a village of the ſame name. It has alſo a well-built populous town, called "Comiſa," near the ſea, on the E. ſide of the iſland, where are the ruins of the ancient city of Meo. N. lat. 43° 25′. E. long. 16° 18′.

Lissa, or *Lechno*, a town of the duchy of Warſaw; raiſed from the condition of a village to that of a town, by the influx of Proteſtants driven by perſecution from Sileſia, Bohemia, Moravia, and Auſtria. The inhabitants carry on a good trade. In this town are a Lutheran and alſo a Calviniſt church, and a ſeminary; 44 miles S.S.W. of Poſen. N. lat. 51° 55′. E. long. 16° 35′.

Lissa, or *Thynnus Lyſſa*, in *Ichthyology*, a name by which ſome authors have called the fiſh more uſually called *gliſſa*, a large ſea-fiſh of the tunny kind.

LISSABATTA, in *Geography*, a town on the N. coaſt of the iſland of Ceram, inhabited by an aſſemblage of different people, which have been troubleſome to the Dutch. S. lat. 2° 55′. E. long. 128° 44′.

LISSANTHE, in *Botany*, ſo named by Mr. R. Brown, from λισσος, *ſmooth*, and ανθη, *a flower*, becauſe of the naked and beardleſs limb of the corolla; that part being denſely covered with hairs in *Leucopogon*, and more or leſs fringed or tufted in ſeveral other genera, of the ſame natural order, found in New Holland. Brown Prodr. Nov. Holl. v. 1. 540. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Epacrideæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of five equal, concave, permanent leaves, ſometimes accompanied by two rather ſmaller ones at the baſe. *Cor.* of one petal, funnel-ſhaped; tube nearly cylindrical, generally hairy within; limb in five lanceolate, equal, ſpreading, beardleſs ſegments. Nectary a five-lobed gland, at the baſe of the germen. *Stam.* Filaments five, ſhort, within the tube; anthers roundiſh, of two cells, burſting lengthwiſe. *Piſt.* Germen ſuperior, globular, with five ſlight angles; ſtyle pentagonal, rigid, ſhorter than the tube; ſtigma obtuſe. *Peric.* Drupa ſucculent. *Nut* hard, of five cells.

Eſſ. Ch. Calyx of five or ſeven leaves. Corolla funnel-ſhaped; its limb beardleſs. Stamens inſerted into the tube, very ſhort. Drupa ſucculent. Nut hard, of five cells.

Mr. Brown defines ſix ſpecies of this genus, ſeparated by him from the *Styphelia* of preceding botaniſts, which are diſpoſed in three ſections. They are ſmall, rigid, upright ſhrubs; with ſcattered leaves, furrowed beneath; and rather ſmall white flowers.

Sect. 1. *Calyx of only five leaves. Cluſters axillary, of few flowers, their partial ſtalks furniſhed with a pair of bracteas at the baſe. Tube of the corolla hairy within.*

1. L. *ſapida.* "Cluſters of two or three flowers, recurved. Leaves oblong-linear, ſharp-pointed, revolute; white and ſtriated beneath." Br.—Gathered by Mr. Brown near Port Jackſon, New South Wales.—By the name, we preſume the fruit is eatable.

2. L. *ſubulata.* "Cluſters of four or five flowers, erect. Leaves linear-awlſhaped. Branches ſmooth. Fruit with ten furrows."—Gathered by Mr. Brown in the ſame country. The *leaves* are about half an inch long.

3. L. *ſtrigoſa.* (Styphelia ſtrigoſa; Sm. New Holl. 48.) Cluſters collected towards the ends of the branches, erect, of few flowers. Leaves linear-awlſhaped. Branches downy. Drupa with five ſlight angles.—Sent from Port Jackſon by Dr. White in 1793. Found there alſo, as well as in Van Diemen's land, by Mr. Brown. The *ſtem* is ſhrubby, rigid, finely downy, with numerous, ſhort, crowded, leafy, lateral branches. *Leaves* ſcattered, ſometimes imperfectly whorled, nearly ſeſſile, about half an inch long, rigid, pungent, revolute; ſmooth, even and convex above; ribbed beneath. *Cluſters* axillary and terminal, generally crowded about the ends of the branches, ſhort, erect, of very few flowers, their ſtalk downy, with ſeveral pale, concave, fringed *bracteas*. *Calyx-leaves* like the bracteas. Tube of the *corolla* thrice as long as the calyx; limb acute, one-third the length of the tube. *Anthers* riſing juſt above the mouth, accompanied by a few erect hairs from the inſide of the tube. *Germen* and lower part of the *ſtyle* clothed with fine, ſhort, hoary down.

Sect. 2. *Calyx of ſeven leaves. Corolla ſhort, its tube and mouth without hairs. Spikes axillary, of few flowers,*

4. L. *montana.* "Leaves oblong-linear, obtuſe, pointleſs; glaucous beneath."—Gathered by Mr. Brown at Van Diemen's land.

Sect. 3. *Calyx of ſeven leaves. Corolla elongated, its mouth beſet with deflexed hairs within the tube. Flowers axillary, ſolitary.*

5. L. *daphnoïdes.* (Styphelia daphnoides; Sm. New Holl. 48.)—Leaves elliptic-lanceolate, ſlightly concave, with a blunt callous point; their edges naked, roughiſh. Sent from Port Jackſon by Dr. White, in 1792. Mr. Brown found it both in the tropical part of New Holland, and in Van Diemen's land. The *ſtem* is much branched, leafy, and finely downy. *Leaves* ſcattered, from $\frac{1}{4}$th to $\frac{3}{4}$ths of an inch long, very various in breadth, more or leſs elliptical, ſmooth, ſlightly concave, entire; minutely roughiſh at the edges; furniſhed with numerous branching ribs beneath. *Flowers* numerous, axillary, ſolitary, on ſhort hairy ſtalks. *Calyx-leaves* all nearly of equal ſize and appearance, ovate, pointed, ſmooth, finely fringed, two of them external. *Corolla* much like that of *L. ſtrigoſa*, but with rather longer and narrower ſegments, whoſe upper ſide appears, as far as we can judge from the dried plant, to be finely downy from their baſe to the middle. Mr. Brown however, who ſaw it alive, deſcribes this part as entirely ſmooth. The aſpect of this pretty ſpecies is much like that of ſome of the ſmaller kinds of *Daphne*.

6. L. *ciliata.* "Leaves elliptic-lanceolate, flat, with a pellucid point; their edges finely ſerrated and fringed. Limb of the corolla roughiſh."—Gathered by Mr. Brown in Van Diemen's land. We have ſeen no ſpecimens of this ſpecies, nor of any others, except the third and fifth, nor do we know of any of them being introduced into the gardens of this country.

LISSER, in *Geography*, a town of Perſia, in the province of Ghilan; 60 miles N.W. of Reſhd.

LISSOUEN, a town of Pruſſia, in Natangen; 15 miles S. of Marggrabowa.

LISSUS, in *Ancient Geography*, a town of Illyria, in Dalmatia, between the mouth of the Drin and the frontier of Macedonia. Ptolemy. Pliny calls it "Liſſum Oppidum," and adds that it was a colony of Roman citizens, 100 miles from Epidaurus, where Macedonia commenced.

LIST, in the *Manufactures*, denotes the border of a ſtuff, or that which bounds its width on each ſide.

Du-Cange derives the word from *liciæ*, which, in the age of corrupt Latin, was uſed for the incloſures of fields and cities, as being anciently made with cords interlaced; or from *liſtæ, quia campum claudebant inſtar liſtarum panni*; as incloſing the ground after the manner that a liſt does a piece of cloth.

All cloths, and ſtuffs of ſilk, wool, or cotton, have liſts. Liſts contribute to the goodneſs of the ſtuff, and farther ſerve to ſhew their quality; which has given occaſion to ſeveral regulations relating to their matter, colour, work, &c.

List is alſo uſed to ſignify the incloſed field, or ground, wherein the ancient knights held their juſts and combats. It was ſo called as being hemmed round with pales, barriers, or ſtakes, as with a liſt.

Some of theſe were double, one for each cavalier; which kept them apart, ſo that they could not come nearer each other than a ſpear's length. See Tournament, and Duel.

List, *Liſtel*, or *Liſtello*, in *Architecture*, called alſo *cincture*, *fillet*, *ſquare*, and *reglet*, is a little ſquare moulding, ſerving to crown or accompany larger mouldings; and, on occaſion, to ſeparate the flutings of columns.

List, in the *Sea Language*, the ſame with *Luſt*.

List, *Civil.* See Civil *liſt*, and Revenue.

LISTENING, according to Rohault, conſiſts in extending or bracing the tympanum of the ear, and putting it into ſuch a condition, as that it ſhall be the more affected by any tremulous motion of the external air. See Ear.

Listening, in the *Manege*, as when we ſay a horſe goes a liſtening pace. See Ecoute.

Listening *Trumpet*. See Trumpet.

LISTER, Martin, in *Biography*, a phyſician and naturaliſt, was born about 1638. He was of a Yorkſhire family, (ſettled in Buckinghamſhire,) which produced a conſiderable number of medical practitioners of reputation; among whom was ſir Matthew Liſter, phyſician to Charles I., and preſident of the College of Phyſicians. Martin was educated under the direction of his uncle, ſir Matthew, and ſent to St. John's college, Cambridge, where he took his firſt degree in arts in 1658. In 1660 he was made fellow of his college by royal mandate. Having made choice of the profeſſion of medicine, he purſued his ſtudies with zeal, and travelled to the continent for the purpoſe of farther improvement. On his return in 1670, he ſettled at York, where he practiſed his profeſſion for many years with conſiderable reputation. At the ſame time he applied all the leiſure, which his avocations allowed him, to the inveſtigation of the natural hiſtory and antiquities of the north of England; and having communicated ſeveral papers on theſe ſubjects to the Royal Society, he was elected a fellow of that body. He contributed many coins, altars, and other antiquities, together with a great number of valuable natural curioſities, to the Aſhmolean muſeum at Oxford. His various productions having made him well known to the learned in the kingdom, upon the ſolicitation of his friends he removed to London in the year 1684. He was at that time created doctor of phyſic by diploma at Oxford, upon the particular recommendation of the chancellor; and was ſoon afterwards elected a fellow of the College of Phyſicians. In 1698 he accompanied the earl of Portland in his embaſſy from king William to the court of France; when, having obtained introductions to the moſt eminent men of ſcience at Paris, he viewed all the curioſities of that capital. On his return he publiſhed an account of this journey, which contained ſome things of a trifling nature, and gave occaſion to a burleſque imitation, entitled "A Journey to London," by Dr. William King. At that time, indeed, when the ſtudy of natural hiſtory was little attended to, a man who had written on ſnails and ſpiders, and beſtowed his attention on the minuteſt parts of natural knowledge, was particularly liable to incur the ridicule of wits. In conſequence of the illneſs of Dr. Hannes, in 1709, Dr. Liſter was made ſecond phyſician in ordinary to queen Anne; an appointment which he did not hold long; for he died in February 1711-12.

The medical writings of this phyſician are not void of valuable obſervations, deduced from his own experience; but they are marked by a propenſity to hypotheſis, and too ſtrong an attachment to ancient doctrines. Theſe are two works on Engliſh medicinal waters, entitled "De Fontibus Medicatis Angliæ, Exercitatio nova et prior," 1682, "altera," 1684: "Exercitationes ſex Medicinales, de quibuſdam morbis chronicis," 1694, which was republiſhed, with additions, in 1697. The diſeaſes here treated of are dropſy, for which he recommends the uſe of draſtic purgatives; diabetes, hydrophobia, ſyphilis, for which he admits that mercury is a ſpecific, but avers that the mercury itſelf requires an antidote, which is found in the guaiacum; ſcurvy, gout, ſtone, and ſmall-pox, for which laſt he extols the remedial effects of the alexipharmic medicines, and condemns the cooling practice introduced by the ſagacious Sydenham. In general, indeed, he is a keen controverſialiſt, and indulges in ſevere remarks upon ſome of his contemporaries, eſpecially Sydenham. In his "Diſſertatio de Humoribus," 1709, which is full of hypotheſes, he is not leſs ſevere in his treatment of Drake and Ruyſch.

The reputation of Liſter is principally founded on his reſearches in natural hiſtory and comparative anatomy. He publiſhed nearly forty papers in the Philoſophical Tranſactions, Nos. 25 to 585 incluſive, in addition to the following works. "Hiſtoriæ Animalium Angliæ Tractatus tres: unus de Araneis: alter de Cochleis, tum terreſtribus, tum fluviatilibus: tertius de Cochleis marinis," 1678, 4to. "Exercitatio Anatomica de Cochleis maxime terreſtribus et Limacibus," 1694, 8vo. "Exercitatio Anatomica altera de Buccinis fluviatilibus et marinis," 1695, 8vo. "Exercitatio Anatomica tertia Conchyliorum bivalvium," 1696, 4to. In all theſe works Dr. Liſter has diſplayed great accuracy of obſervation, and indefatigable induſtry, in detecting the moſt minute and curious particulars of the economy of theſe creatures. He alſo edited a correct and better arranged copy of Goedart's Treatiſe on Inſects, in 1685; and an edition of Sanctorius's "Medicina Statica," with a commentary, in 1701. His "Journey to Paris," notwithſtanding the efforts of ridicule, was well received, and contains a variety of curious matter. Gen. Biog. Hutchinſon, Biog. Med. Eloy Dict. Hiſt.

LISTERLAND, in *Geography*, a cape on the S. coaſt of Norway; 20 miles N.W. of Lindeſneſs.

LISTING, or INLISTING, in *Military Language*, denotes the retaining and enrolling ſoldiers, as volunteers, for the national ſervice. When any perſon is inliſted as a ſoldier, he ſhall within four days, but not ſooner than twenty-four hours, be taken before the next juſtice of peace, or chief magiſtrate of a town corporate, not being an officer in the army; and before him ſhall be at liberty to declare his diſſent to ſuch inliſting; and on ſuch declaration, and returning the inliſting money, and paying 20*s.* for the charges expended on him, he ſhall be forthwith diſcharged, in preſence of ſuch magiſtrate. But if he ſhall refuſe or neglect in twenty-four hours to return and pay ſuch money, he ſhall be deemed to be inliſted, as if he had given his aſſent before the magiſtrate. If he declare that he voluntarily inliſted himſelf, the magiſtrate ſhall certify under his hand, that ſuch perſon is duly inliſted, ſetting forth the place of his birth, age, and calling, if known; and that the third and fourth articles of the ſecond ſection, and the firſt article of the ſixth ſection of the articles of war againſt mutiny and deſertion were read to him, and that he has taken the oaths mentioned in the ſaid articles of war; *viz.* the oath of fidelity and the oaths in the ſchedules marked A and B; except in the caſe of recruits inliſted either in his majeſty's ſervice or in the Eaſt India company's forces under 39 Geo. III. c. 109, in which caſe each recruit ſhall, inſtead of the ſaid oath of fidelity, and that contained in the ſchedule A or B, take the oath of allegiance directed by the 39th of the king, and contained in ſchedule E, and the juſtice or magiſtrate ſhall certify ſuch inliſtment and ſwearing according to the ſchedule F; and if any perſon ſo certified as duly inliſted ſhall refuſe to take the ſaid oath of fidelity before ſuch magiſtrate, &c. the officer, from whom he hath received ſuch money, may detain and confine him till he ſhall take it; and every military officer that ſhall herein offend, ſhall be caſhiered and diſplaced from their office, and diſabled from holding any military poſt, and forfeit 50*l.* See FOREIGN *ſervice.*

LISTOWHILL, or LISTOWELL, in *Geography*, a poſt-town of Ireland, in the county of Kerry, ſituated on the river Feale. The caſtle, on the ſummit of a ſteep precipice above the river, was the laſt ſtrong hold which held out againſt queen Elizabeth in 1600. It is 131 miles S.W. by W. from Dublin, and 13 N.E. from Tralee.

LISTVENNISCHNA, a town of Ruſſia, in the government of Irkutſk, on the Argun, on the confines of China. N. lat. 51° 44′. E. long. 121° 20′.

LIT, a town of Sweden, in Jamtland; 10 miles N. of Oſterſund.

LITA, in *Botany*, ſo named by Schreber, from λιτος, *ſimple*, *naked*, or *deſtitute*, becauſe the plant conſiſts chiefly of flowers, with a very trifling ſtem, and no leaves, but a few ſmall ſcales. Schreb. 795. Willd. Sp. Pl. v. 1. 1071. Mart. Mill. Dict. v. 3. (Voyria; Aubl. Guian. v. 1. 208. Vohiria; Juſſ. 141. Lamarck Illuſtr. t. 109.—Claſs and order, *Pentandria Monogynia.* Nat. Ord. *Rotaceæ*, Linn. *Gentianæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, tubular, erect, coloured, five-cleft, acute, permanent. *Cor.* of one petal, ſalver ſhaped; tube cylindrical, very long, dilated at the top and bottom; limb in five equal, ovate, ſpreading, deep ſegments. *Stam.* Filaments ſcarcely any; anthers five, roundiſh, two-lobed, nearly ſeſſile, in the throat of the tube. *Piſt.* Germen ſuperior, ovate-oblong; ſtyle thread-ſhaped, the length of the tube; ſtigma capitate, abrupt. *Peric.* Capſule oblong, of one cell and two valves. *Seeds* very numerous, minute, chaffy, attached to the inflexed margins of the valves.

Eſſ. Ch. Corolla ſalver-ſhaped. Anthers ſeſſile, within the tube. Stigma abrupt, undivided. Capſule of one cell and two valves.

1. L. *roſea.* Willd. n. 1. (Voyria roſea; Aubl. Guian. v. 1. 209. t. 83. f. 1.)—Flowers in pairs. Segments of the corolla acute. Root tuberous.—Gathered by Aublet in the foreſts of Guiana, where the natives call it *Voyria,* and eat the roaſted *root,* which is tuberous, reſembling a potatoe in ſhape and flavour, and throws out various ſpreading fibres. The *ſtem* is ſolitary, ſeveral inches long, chiefly concealed under the ground, ſquare, knotty, ſmooth, bearing ſeveral, oppoſite or ternate, little, acute, fleſhy ſcales, inſtead of *leaves,* in the manner of a *Lathræa,* and dividing at the top, where it riſes above the ſurface, into ſeveral branches about an inch long, with more frequent knots, and rather larger ſcales. Each branch bears two large and handſome, roſe-coloured *flowers,* whoſe *tube* is near two inches long, ſwelling at the top as well as at the baſe, but contracted again at the orifice. The *limb* is about half an inch in diameter, ſpreading like a ſtar, with ſharp points. *Calyx* ſhort, bell-ſhaped. Sometimes the *flowers* are ſolitary.

2. L. *cærulea.* Willd. n. 2. (Voyria cærulea; Aubl. Guian. v. 1. 211. t. 83. f. 2.)—Flowers in pairs. Segments of the corolla rounded, obtuſe. Root tuberous.—Native of palm foreſts in Guiana, where it bloſſoms in May. This differs from the preceding in having blue *flowers,* whoſe limb is larger, with round or obovate blunt ſegments, and a more dilated orifice; as well as a more deeply cut calyx. Aublet ſays the flowers are occaſionally ſix-cleft, with ſix *ſtamens.*

3. L. *lutea.* (Gentiana aphylla; Jacq. Amer. 87. t. 60. f. 3. Helleborine aphyllos, flore luteo; Plum. Cat. 9?)—Stems ſimple, ſingle-flowered. Segments of the corolla acute. Root fibrous, faſciculated. Gathered by Jacquin, flowering in May as well as December, in the extenſive damp mountainous foreſts of Martinico. It is a ſmall and tender plant, evidently akin, as Aublet remarks, to his two ſpecies above deſcribed; though the *root* conſiſts only of thick entangled fibres. *Stems* four inches high, of a ſhining ſtraw-colour, jointed, ſingle-flowered, bearing ſeveral pairs of minute, oppoſite, acute ſcales. *Flowers* an inch long, ſlender, yellowiſh, inodorous, with a ſmall, acute, ſtellated border. Their *ſtigma* is deſcribed as ſimple, capitate, and obtuſe, as it ought by analogy to be, though in the figure repreſented cloven.

LITADA, in *Geography,* a town of the iſland of Negroponte, in the Grecian Archipelago; 48 miles N.W. of Negroponte.

LITANY, an old church term, applied to the proceſſions, prayers, and ſupplications uſed for appeaſing the wrath of God, averting his judgments, or procuring his mercies.

The word comes from the Greek λιτανεια, *ſupplication;* of λιτανεύω, *I beſeech.* Pezron would go farther, and derive the λιτομαι, or λισσομαι, of the Greeks, from the Celtic *lit, feaſt, ſolemnity.*

Eccleſiaſtical authors, and the Roman order, by the word litany uſually mean the people who compoſe the proceſſion, and aſſiſt at it; and Du-Cange obſerves, that the word anciently ſignified *proceſſion.*

Simon of Theſſalonica mentions, that, in the ancient litanies, the people went out of the church, to denote the fall of Adam; and returned into it again, to ſhew the return of a pious ſoul to God by repentance.

Litany, in a modern ſenſe, denotes a form of prayer, ſung or ſaid in churches; conſiſting of ſeveral periods, or articles; at the end of each of which is an invocation in the ſame terms.

Before the laſt review of the common prayer, the litany was a diſtinct ſervice by itſelf, and uſed ſome time after the morning prayer was over. At preſent it is made one office with the morning ſervice, being ordered to be read after the third collect for grace, inſtead of the interceſſional prayers in the daily ſervice.

It has been obſerved, that none but thoſe who are avowed Trinitarians can conſcientiouſly join in this part of the church ſervice; it has been alſo obſerved, that in the petition to be delivered from "all deadly ſin," there ſeems to be an intimation of the popiſh doctrine of venial and mortal or deadly ſin, and that the petition in the maſs-book, from which a great part of the litany is taken, for deliverance from "ſudden death," is more guardedly expreſſed, "à ſubitâ et improviſâ morte," *i. e.* from death ſudden and unprovided for.

LITAO, in *Geography,* a town on the N.W. coaſt of the iſland of Timor. S. lat. 9° 2'. E. long. 124° 42'.

LITCHFIELD. See Lichfield.

Litchfield, a townſhip of America, in Lincoln county, Maine, 45 miles from Hallowell; containing 1044 inhabitants.—Alſo, a townſhip in Hillſborough county, New Hampſhire, ſituated on the E. ſide of Merrimack river, about 54 miles W. of Portſmouth: ſettled in 1749 and containing, in 1800, 372 inhabitants.—Alſo, a populous and hilly county of Connecticut, bounded N. by Maſſachuſetts, S. by New Haven and Fairfield counties, E. by Hartford, and W. by New York. It is divided into 20 townſhips, containing 41,214 inhabitants. Although the face of the country is generally mountainous, the ſoil is fertile, yielding large crops of wheat and Indian corn, and affording fine paſture. The inhabitants are almoſt univerſally farmers, and wholly detached from maritime commerce.—Alſo, the chief and poſt-town of the above county, ſeated on an elevated plain, expoſed to the cold winds of winter, but enjoying a large portion of the refreſhing breezes of ſummer. Its ſituation is handſome, and it contains about 60 or 70 compact dwelling-houſes, a court-houſe, a meeting-houſe, and 4285 inhabitants; 32 miles W. of Hartford. N. lat. 41° 46'. W. long. 73° 37'. On ſeveral ſmall ſtreams, ſome of which fall into Great Pond, a beautiful ſheet of water, are three iron-works, an oil-mill, and a number of ſaw and griſt-mills.—Alſo, a townſhip in Herkemer county, New York, taken from German Flats, incorporated in 1796, and containing 1976 inhabitants. Morſe.

LIT-CHI, or Lichi, in *Botany,* Sonnerat Voy. v. 2. 230. t. 129, a valuable Chineſe fruit, which, after being dried in an oven, becomes an object of commerce. It is globoſe, the ſize of a ſmall walnut, conſiſting of a thick tuberculated coat, encloſing a large hard ſeed, enveloped in a quantity of pleaſantly acid pulp. See Euphoria, Scytalia, and Dimocarpus.

LI-TCHUEN, in *Geography,* a town of Corea; 15 miles N.W. of Long-kouang.

LITE, the name of a plaſter much commended by the ancients: it conſiſted of verdigris, wax, and reſin. Whatever virtues this plaſter poſſeſſed, might be probably found in the melilot plaſter of the ſhops in general, till the late reformation made by the London Pharmacopeia, the colour being generally given by our wholeſale dealers with verdigris, not with the juice of the herb from which it took its name.

LITERÆ Communicatoriæ, in *Church Hiſtory*, letters granted by the biſhops to penitents, when the time of their penance was finiſhed, by which they were again received into the communion of the faithful.

LITERAL Algebra. See Algebra.

Literal *Character*. See Character.

Literalis *Calculus*. See Calculus.

LITERARY Property, is that property which an author, or his aſſignee, may be ſuppoſed to have in his own literary compoſitions; ſo that no other perſon without his leave may publiſh or make profit of the copies. The Roman law adjudged, that if one man wrote any thing on the paper or parchment of another, the writing ſhould belong to the owner of the blank materials (Juſt. 2. 1. 33.); meaning thereby the mechanical operation of writing, for which it directed, the ſcribe to receive a ſatisfaction; for, in works of genius and invention, as in painting on another man's canvas, the ſame law gave the canvas to the painter. As to any other property in the works of the underſtanding, the law is ſilent; though the ſale of literary copies, for the purpoſes of recital or multiplication, is certainly as ancient as the times of Terence (Prolog. in Eunuch. 20.), Martial (Epigr. i. 67. iv. 72. xiii. 3. xiv. 194.), and Statius (Juv. vii. 85.) Neither with us in England hath there been, till ſome few years ago, any final determination upon the right of authors at the common law. In caſe of a bargain for a ſingle impreſſion, or a ſale or gift of the copy-right, the reverſion is plainly continued in the original proprietor, or the whole property is transferred to another. It has been a queſtion much agitated in our ſuperior courts of judicature, and at length determined by the houſe of lords againſt authors and their aſſigns, whether the copy-right of a book belongs to the author by common law. But, excluſive of ſuch copy-right as may ſubſiſt by the rules of the common law, the ſtatute 8 Ann. cap. 19, amended by ſtatute 15 Geo. III. c. 53, has protected, by additional penalties, the property of authors and their aſſigns for the term of fourteen years, and hath directed, that if, at the end of that term the author himſelf be living, the right ſhall then return to him for another term of the ſame duration: and this is the ſole right now veſted in the proprietors of copies. By the ſtatute 15 Geo. III. c. 53, ſome additional privileges in this reſpect are granted to the univerſities, and certain other learned ſocieties. A ſimilar privilege is extended to the inventors of prints and engravings, for the term of twenty-eight years, by 8 Geo. II. cap. 13. and 7 Geo. III. cap. 38. beſides an action for damages, with double coſts, by ſtatute 17 Geo. III. c. 57. All which parliamentary protections appear to have been ſuggeſted by the exception in the ſtatute of monopolies, 21 Jac. I. c. 3, which allows a royal patent of privilege to be granted for fourteen years to any inventor of a new manufacture, for the ſole working or making of the ſame; by virtue whereof it is held, that a temporary property therein becomes veſted in the king's patentee. 1 Vern. 62.

Literary *Criticiſm*. See Criticism.

LITERATI, Letrados, lettered, an epithet given to ſuch perſons, among the Chineſe, as are able to read and write their language.

The literati alone are capable of being made mandarins.

The literati form the moſt diſtinguiſhed part of the Chineſe nation. Since the dynaſty of Han, *i. e.* for more than 2000 years, they have conſtantly held the chief rank in the empire; and it is always from among them that maſters are choſen for the education of youth; miniſters, for the adminiſtration of public affairs; and magiſtrates, for judging the people: in a word, the literati are, in ſome meaſure, the ſoul of the Chineſe nation; ſince it is from them that it receives its moral exiſtence, and its civil and political being. The literati muſt therefore be very numerous in a ſtate, where they enjoy every diſtinction attached to pre-eminence, and where every thing favours their increaſe. Since learning is the only means that conduct to honours, it is neceſſary that thoſe who aſpire to them ſhould cultivate letters; and they muſt make it appear, that they have cultivated them with ſucceſs, before they can obtain any civil employment. To guard againſt impoſition, government has fixed for every city of the firſt, ſecond, and third claſs the number of literati who can be legally promoted every year to the firſt degree of literature, which is that of "ſieou-tſai," and which anſwers to bachelor of arts in our univerſities. Every "ſieou-tſai" is accounted noble, and is never enrolled among the taxables. Of theſe there are reckoned to be in China 24,701 individuals, who are annually introduced to the firſt degree of literati; and the number of thoſe admitted before may be ſuppoſed to be at leaſt 20 times as great. According to this eſtimate there are always in China 494,020 literati, who have taken degrees, and who are, conſequently, not included among the taxables. See Mandarins.

Literati is alſo the name of a particular ſect, either in religion, philoſophy, or politics; conſiſting principally of the learned men of that country: among whom it is called *jukiao*, i. e. *learned*.

It had its riſe in the year of Chriſt 1400, when the emperor, to awaken the native affection of the people for knowledge, which had been quite baniſhed by the preceding civil wars among them, and to ſtir up emulation among the mandarins, choſe out forty-two of the ableſt among their doctors, to whom he gave a commiſſion to compoſe a body of doctrine, agreeable to that of the ancients, which was then become the rule, or ſtandard, of the learned. The delegates applied themſelves to the buſineſs with very great attention; but ſome fancied them rather to have wreſted the doctrine of the ancients, to make it conſiſt with their's, than to have built up their's on the model of the ancients.

They ſpeak of the Deity, as if it were no more than mere nature, or the natural power or virtue, that produces, diſpoſes, and preſerves the ſeveral parts of the univerſe. It is, ſay they, a pure, perfect principle, without beginning or end; it is the ſource of all things, the eſſence of every being, and that which determines it to be what it is. They make God the ſoul of the world: they ſay he is diffuſed throughout all matter, and produces all the changes that happen there. In ſhort, it is not eaſy to determine, whether they reſolve God into nature, or lift up nature into God; for they aſcribe to it many of thoſe things which we attribute to God.

This doctrine, in lieu of the idolatry that prevailed before, introduced a refined kind of atheiſm. The work, being compoſed by ſo many perſons of learning and parts, and approved by the emperor himſelf, was received with infinite applauſe by all the people. Many were pleaſed with it, becauſe it ſeemed to ſubvert all religion; others approved it, becauſe the little religion that is left them, could not give them much trouble. And thus was formed the ſect of the Literati; which conſiſts of the maintainers and adherents to this doctrine.

The court, the mandarins, and the perſons of fortune and quality, &c. are generally retainers to it; but a great part of the common people ſtill hold to their worſhip of idols.

The literati freely tolerate the Mahometans, becauſe they adore, with them, the king of heaven, and author of nature; but they bear a perfect averſion to all ſorts of idolaters among them: and it was once reſolved to extirpate them. But the diſorder this would have occaſioned in the empire prevented it: they now content themſelves with condemning them in general, as hereſies; which they do ſolemnly every year at Pekin.

LITERNUM, or Linternum, in *Ancient Geography*, a town of Italy, in Campania, at the mouth of the Clanis, and near the lake called by Statius "Linterna Palus." It was a Roman colony, improved and enlarged by Auguſtus. The ruins of it, conſiſting of ſome heaps of ſtones, may be traced on the edge of a large pond in a dreary flat ſhore, between the mouth of the Vulturnus and the promontory of Miſenum. Hither Scipio Africanus withdrew from the accuſations of his enemies, and here he ſpent his days in retirement. Tradition ſays, that his aſhes were depoſited in this place.

LITHAGOGI, of λιθος, *ſtone*, and αγω, *I bring away*, an epithet given by ſome medical writers to ſuch medicines as work by urine, and are ſuppoſed to have the virtue of expelling the ſtone.

LITHAGROSTIS, in *Botany*, from λιθος, *a ſtone*, and αγρωστις, *graſs*, a name faulty in itſelf, as compoſed of that of another eſtabliſhed genus, and quite unneceſſary. Gærtner contrived it for the *Coix* of Linnæus, Juſſieu, and others, becauſe the κοιξ of Theophraſtus ſeems to be a ſort of palm. But there is no end of ſuch critical alterations, eſpecially when they are not founded on any thing like certainty.

LITHANTHRAX, of λιθος, *ſtone*, and ανθραξ, *coal*, in *Natural Hiſtory*, is uſed as the name of the common pit coal. See Coal.

LITHARGE, compoſed of λιθος, *a ſtone*, and αργυρος, *ſilver*, a metalline ſubſtance, formed of the ſpume of lead; or, it is a calx of lead in an imperfect ſtate of vitrification. When ſilver is refined by cupellation with lead, this latter metal, which is purified, and which cauſes the ſcorification of the imperfect metals alloyed with the ſilver, is transformed into a matter compoſed of ſmall ſemi-tranſparent ſhining plates, reſembling mica, which is *litharge*. See *Alloys of* Lead.

This preparation of lead is of great uſe in roaſting the ſtubborn ores of gold, ſilver, and copper; for it melts all kinds of ſtones and earth into glaſs, ſooner than the metals; and by this means the metal, which is heavier, will fall through the glaſs, which is a thin and light ſubſtance, and will be collected under it into a regulus, with only a few duſty ſcoriæ adhering to it. But if it be copper that is thus ſeparated, a ſmall portion of it is always deſtroyed; and if gold or ſilver, a like ſmall portion is always lodged and detained in the ſcoriæ.

But as the litharge penetrates through all ſorts of veſſels, and while melting riſes into a ſcum, that often runs over their edges, the aſſayers never uſe it alone, but always mix with it ſuch ſubſtances as may give it a clamminefs, ſuch as flints, ſands, clay, or the like: they mix two parts of litharge with one part of any of theſe ſubſtances, and add ſome nitre, or common ſalt, that the whole may run the more eaſily. They ſhut up the veſſels, which muſt be made very thick and ſolid, with a ſmall cover or lid, cut cloſe, and placing this in a wind-furnace, they keep it in fuſion a quarter of an hour, looking at times into the aſh-hole, to ſee if the glaſs have not eſcaped through the veſſel, and run down thither. Very often it is found ſweating through the ſides of the veſſel, like water, and falling in drops into the aſh-hole; and in this caſe, there is no way to preſerve the remainder, but to take the veſſel out of the fire.

When the whole is cool, the veſſel muſt be broke, and at the bottom there will be found a ſmall quantity of a regulus of lead, revived by means of the ſalt; in the middle, the glaſs of lead, which muſt be kept for uſe; and at the top a ſaline cruſt, which is to be thrown away.

Litharge is more or leſs white or red, according to the metals with which the ſilver was alloyed. Accordingly the white is called litharge of ſilver, and the red has been improperly called litharge of gold.

Litharge may be eaſily revived into lead; accordingly, much of that which is produced by refining in great is reduced, by being melted upon burning coals. The part which is leaſt altered by mixture with other metals is thus reduced, and thus good and ſaleable lead is obtained. The reſt of the litharge of theſe refineries is ſold and uſed for various purpoſes.

The potters uſe much of it to give a beautiful gloſs to their wares; it is alſo employed in the compoſition of ſome glaſſes, for it is very fuſible, and aſſiſts the fuſion of other ſubſtances; and it is alſo uſed by painters, dyers, ſkinners, and glaziers. When mixed with wine, it gives it a bright ſprightly colour, but renders it extremely unwholeſome. In general, it has the ſame properties with the other calces of lead. The litharge commonly ſold is obtained from refineries, and the quantity thus procured is more than ſufficient for the demand. It is employed for the preparation of ſome plaſters and other external remedies. See Lead.

Litharge, *Plaſter of.* See Emplastrum *commune.*

Litharge, *Vinegar of.* See Vinegar *of Lead.*

LITHAY, or Litay, in *Geography*, a town of the duchy of Carniola, on the Save; 15 miles E. of Laybach. N. lat. 46° 3'. E. long. 15°.

LITHIASIS, (from λιθος, *a ſtone*,) in *Surgery*, the diſorder in which calculous concretions are formed in the urinary organs, and more eſpecially in the bladder, occaſioning a variety of ſymptoms dependent upon their ſhape, ſize, and ſituation. For further details upon this ſubject, ſee Lithotomy and Stone.

LITHIC, or Uric Acid. See Urinary *Calculus.*

LITHIDIA, a name which, in Hill's Hiſtory of Foſſils, is given to an aſſemblage of ſtones of the ſiliceous claſs, belonging to the quartz and flint tribes.

LITHOBOLIA, Λιθοβολια, in *Antiquity*, a feſtival celebrated by the Træzenians, in memory of Lamia and Auxeſia, two virgins, that coming from Crete to Træzene, in a time of tumult and ſedition, became a ſacrifice to the fury of the people, by whom they were ſtoned to death.

Lithobolia, or *Lapidation*, was alſo a common puniſhment inflicted by the primitive Greeks upon ſuch as were taken in adultery.

LITHOCOLLA, or Lithocollum, formed of the Greek λιθος, *ſtone*, and κολλα, *glue*, a cement uſed by the lapidaries to faſten their precious ſtones, in order for cutting them.

It is compoſed of reſin and brick-duſt. For diamonds, they uſe melted lead, putting them into it before it be quite cold: for other cements, they mix marble-duſt with ſtrong glue; and, to faſten their ſparks, add the white of an egg, and pitch. See Cæment.

LITHODÆMON, or Lapis *Dæmonum*, a name given by ſome authors to jet.

LITHODENDRON, a name by which, according to Dioſcorides, many of the ancients expreſs the common red coral.

LITHOGENESIA, a term uſed by ſome authors to expreſs the formation and original of ſtones.

LITHOLABON, a name given by ſome chirurgical writers to an inſtrument uſed in the operation of lithotomy; it is a forceps intended for taking hold of the ſtone.

LITHOLOGY, the ſyſtematical arrangement of ſtones; which ſee.

LITHOMANTIA, Λιθομαντεια, in *Antiquity*, a ſpecies of divination performed with ſtones. Sometimes the ſtone called *ſiderites* was uſed: this they waſhed in ſpring-water in the night by candle-light; the perſon that conſulted it, was to be purified from all manner of pollution, and to have his face covered: this done, he repeated divers prayers, and placed certain characters in an appointed order; and then the ſtone moved of itſelf, and in a ſoft, gentle murmur (or as ſome ſay) in a voice like that of a child, returned an anſwer. By a ſtone of this nature, Helena is reported to have foretold the deſtruction of Troy.

LITHOMARGE, *Steinmark*, Wern. *Argile lithomarge*, Haüy. *Steinmärg*, or *Sjoſkum*, Swed.

This ſubſtance, which is related to the ſmectic kinds of clay and to ſteatite, occurs friable and compact.

1. *Friable lithomarge. Zerreibliches ſteinmark*, Wern.

Its colour is ſnow-white, oftener yellowiſh, and ſometimes reddiſh-white.

It is found maſſive, diſſeminated, and in cruſts, conſiſting of fine, dull, ſometimes feebly glimmering ſcaly particles, which are either coherent or looſe.

It is light, rather greaſy to the touch, but adheres to the tongue. Streak ſhining.

It occurs in Saxony, on the Hartz, &c. generally in ſmall maſſes, particularly in metalliferous veins.

A variety from the Hartz, where it occurs in grey wacke, ſhews phoſphoreſcence by friction.

2. *Compact or indurated lithomarge. Feſtes ſteinmark*, Wern.

Its colours, beſides thoſe of the friable lithomarge, are pearl-grey, lavender and purpliſh-blue, yellowiſh-grey, ſeveral ſhades of ochre yellow, and alſo fleſh-red; ſeveral of theſe colours frequently occurring together as clouded, veined, ſtriped, and ſpotted delineations.

It is found maſſive.

Internally it is dull. Streak ſhining.

Fracture large and flat conchoidal, paſſing into even and fine earthy; fragments indeterminately angular, blunt-edged.

It is very ſoft and mild, and eaſily frangible; greaſy to the touch, but ſtrongly adhering to the tongue. It is light.

The variegated bluiſh and purpliſh earth, vulgarly called *Wunder-erde* in German, or *Terra miraculoſa Saxonica*, is one of the beſt known and fineſt variety of lithomarge. It is found at Planitz, near Zwickau, in Saxony, in beds of coal. A fine fleſh-red variety occurs at Rochlitz in Saxony, in diſintegrated porphyry. Lithomarge is alſo met with in ſeveral other parts of Saxony, and on the Hartz, in Bohemia, Moravia, Bavaria, and Siberia.

Compact lithomarge is partly found in veins, ſuch as tin ſtone veins, partly, as that of Planitz, on beds of coal; alſo (the yellow variety) in the cryſtalline geodes of the Topaze rock, in baſalt and amygdaloid. At Zöblitz, in Saxony, it occurs in ſerpentine.

This ſubſtance, of which we are ſtill without a good chemical analyſis, appears to paſs into ſteatite, meer-ſchaum, and alſo into variegated clay.

It has been frequently confounded by authors with porcelain earth, fullers' earth, bole, &c.

The variety of lithomarge occurring in ſerpentine, is uſed for poliſhing this latter ſtone. It was alſo formerly employed in medicine, particularly the variegated variety, which was dignified with the appellation of *terra miraculoſa*.

LITHONTRIPTICON Tulpii, the name of a famous diuretic medicine, invented by Tulpius, and given with great ſucceſs in caſes of the ſtone, but requiring great judgment and caution in the adminiſtering of it.

The preparation is this: take a drachm of cantharides without their wings, and a drachm of leſſer cardamoms without their huſks, powder them fine, and pour upon them an ounce of rectified ſpirit of wine, and half an ounce of ſpirit of nitre; ſet them to infuſe, without heat, for five or ſix days, ſtirring them from time to time. The phial muſt not be ſtopped cloſe; becauſe, if it be, the continual fermentation will burſt it. The doſe is from fourteen to fifteen, or twenty drops, in a glaſs of wine and water. It is to be taken in a morning, an hour after eating a meſs of broth, and may be repeated for three or four days.

It is remarkable, that this mixture never ceaſes fermenting for many years; but if it be too faſt corked, will break the glaſs; if it be ſlightly ſtopped, it only throws out the cork with an exploſion. Mem. de l'Acad. Par. 1709. p. 358. edit. Par.

LITHONTRIPTICS, or as it is perhaps more correctly written, Lithonthryptics, in *Medicine*, from the Greek λιθος, a *ſtone*, and θρυπτω, *I break*, ſuch medicines as were ſuppoſed to poſſeſs the property of diſſolving the ſtone in the bladder and kidneys. See Stone.

Various ſimple and compound drugs were believed to be capable of diſſolving the calculous concretions of the urinary paſſages, in ancient times. Theſe medicines, however, had been but too generally found, by modern practitioners, to be deſtitute of any active power of this ſort, when, in the former part of the laſt century, a new ſolvent for the ſtone was announced by a lady, with ſo much evidence in favour of its efficacy, that the Engliſh parliament granted her a large pecuniary reward for divulging the ſecret, and medical practitioners reſorted to it with eagerneſs, and inveſtigated its properties with great care, and in many inſtances had the ſatisfaction to obſerve a temporary removal of the diſtreſſing ſymptoms ſucceed to its uſe. It appeared, however, ultimately, that the ſolvent power of Mrs. Stephens's medicine was a gratuitous ſuppoſition; for on examining, after death, the bodies of the perſons in thoſe very inſtances, on the ſucceſs of which the reward was given, it was diſcovered that the ſtones had all the time remained in the bladders of the patients, though they were ſuppoſed to have been voided by the gradual ſolution of them effected by the medicines.

The principal inſtance of a ſuppoſed cure which was brought forward, was that of Mr. Gardiner. This man was examined in December 1748, by able ſurgeons, and found to have a ſtone in his bladder; after this he took Mrs. Stephens's medicines for eight months without intermiſſion; and at the end of that time he declared himſelf free from all his uſual complaints; and on ſearching him no ſtone was perceived in the bladder. Mr. Gardiner died about three years afterwards, and his body was opened. When the bladder was examined, there were found in it ſix preternatural apertures of different ſizes, the largeſt of which was capable of admitting the end of a finger. Theſe paſſages led to morbidly formed ſacs in the internal coat of the bladder, which ſhielded the calculi from the touch of the ſurgeon's ſounding ſtaff. In a word, though the ſubject was taken up by Dr. Hartley and others, and the medicine believed by ſome to poſſeſs all the powers which had been aſcribed to it; it was not only found, in ſeveral inſtances, that the calculi ſtill remained in the bladder after death; but the diſtreſſing ſymptoms were found to recur, or even to reſiſt the influence of the medicine, in a great many others.

Mrs. Stephens's medicine conſiſted principally of *ſoap*, and *lime*, prepared from ſhells; *i. e.* of lime, a fixed alkali, and a little oil. From theoretical notions, the celebrated Dr. Mead pronounced that a medicine containing ſuch cauſtic materials as *lime*, muſt injure the bladder by its corroſive powers, and therefore condemned the internal adminiſtration of it. Yet he did not know whether the lime could actually reach the bladder through the medium of the circulation with its cauſtic powers unchanged; a circumſtance which the inveſtigations of modern chemiſtry render improbable. And as for the ſubſtitute, ſoap-lees, which had been propoſed for the lime, he thought it ſcarcely leſs ſafe than the former. Dr. Whytt, of Edinburgh, after conſidering the inconveniences of this celebrated ſpecific, reſolved to omit the ſoap, and to try what virtues lime-water might have in diſſolving calculus; and he made many experiments on the qualities of the varieties of lime-water, made with the lime from lime-ſtone, and that from oyſter ſhells, upon fragments of urinary calculi immerſed in it. He concluded by recommending the copious potation of lime-water from ſhells, and adduced ſeveral inſtances of the beneficial effects of this remedy.

Now the truth appears to be, according to the reſult of more accurate obſervation, that all the alkaline and abſorbent medicines, potaſh, ſoda, lime, magneſia, &c. and eſpecially the alkalies, are capable of affording very material relief to the diſtreſſing feelings, connected with the preſence of calculi in the urinary paſſages; that they operate as preventives of a farther increaſe of the bulk and quantity of theſe concretions; but that they do not reach the urinary organs (after having paſſed the organs of the digeſtion, been taken up by the lacteals, and mixed and circulated with the blood) unchanged in their chemical qualities, or in a ſufficient quantity to produce any diminution of the calculi already exiſting there.

They ſeem to poſſeſs this preventive power, however, by their operation in the firſt paſſages. It is now known, that the ordinary calculus of the bladder and kidnies conſiſts of a peculiar animal *acid*, which has been called the *uric* or *lithic* acid, from its abundant exiſtence in the urine and its calculi. Now, although this acid is not formed in the chyle, or any of the fluids in the firſt paſſages; yet its rudiments appear to exiſt there; and experience has determined, that whatever diminiſhes the formation of acidity in the organs of digeſtion, diminiſhes alſo the quantity of the *uric* acid which ſhews itſelf in the urine, and *vice verſâ*. But it is the peculiar property of the alkalies and abſorbent earths, to neutralize acidity of every deſcription; and the alkalies are poſſeſſed of this property in a greater degree than the earths. Whence we may readily perceive how the uſe of theſe medicines, by neutralizing the acids, which are produced by a morbid or imperfect digeſtion of the food, and preventing the formation of that matter, which concretes in the urine into calculi, ſhould give material relief to the patient. It is not, however, very eaſy to underſtand how the prevention of this formation ſhould give ſo much relief, while the original concretion remains in the bladder, undiminiſhed in weight and ſize. Whether its ſurface becomes more uniformly ſmooth and leſs irritating, therefore, to the internal coat of the bladder, under the uſe of theſe medicines, it would be very difficult to aſcertain, ſince we have no opportunity of comparing its previous condition.

It is farther to be obſerved, however, that there is one variety of calculus found in the urinary paſſages, for which the alkalies and abſorbents are incapable of affording any relief; as, from its chemical compoſition, it is altogether inſoluble in theſe ſubſtances, even when directly immerſed in them. It is a triple ſalt formed by combination with the phoſphoric acid, and is, therefore, only to be diſſolved or decompoſed by an agent of a directly oppoſite quality to that of the alkalies; namely, by a mineral acid, which unites with the earthy and alkaline baſe. See NEPHRALGIA and STONE.

Dr. Hartley has publiſhed, in the London Gazette, the following receipt for making a lithontriptic electuary. Take five pounds of Alicant ſoap, ſhaved, and one pound of oyſter-ſhell-lime: put them into a tin veſſel, and pour upon them five quarts of water; make the water boil, till the ſoap be perfectly diſſolved in it, and then ſtrain all into a glazed earthen veſſel. Expoſe the maſs to the air, ſtirring it every day till it becomes both mild to the taſte, and of a proper conſiſtence to be formed into pills, or long pellets, without ſticking to the fingers. This may be expected to happen in two or three months. If it becomes ſufficiently mild before it has acquired a due conſiſtence, it may be brought to this, by being heated over the fire, in a tin veſſel: if it acquires a too hard conſiſtence, before it is ſufficiently mild, it muſt be ſoftened with water. This is what the doctor calls the lithontriptic maſs or electuary; which he orders to be made in a tin veſſel, becauſe a braſs or copper one would make it emetic.

He gives another more expeditious way of making it, which is this; pour two gallons of water upon a pound of oyſter-ſhell-lime; ſtir it two or three times, and when it has fallen to the bottom, pour off the clear part of the water. Repeat this fifteen or twenty times, or till the clear water, which is poured off, be almoſt taſteleſs; leaving about five pints of water upon the lime, after the laſt ablution. Then pour this mixture of water and dulcified lime upon five pounds of Alicant ſoap, ſhaved; and proceed as directed in the firſt receipt. The maſs, prepared in this manner, will be fit for uſe in a few days, or even immediately; but then the doctor prefers the foregoing receipt, where time can be allowed for it.

If the maſs of ſoap, and oyſter-ſhell-lime, dulcified in either of the above-mentioned ways, be made of the conſiſtence of an electuary, it is then called the lithontriptic electuary; which for cure is more convenient than the maſs, for thoſe who deſire to take the medicine diſſolved in a liquid vehicle, as milk, water ſweetened with honey or ſugar, water flavoured with brandy or rum, and ſmall beer.

Where a perſon is ſuppoſed to have a large ſtone in the kidnies or bladder, he ought to take every day as much of the maſs or electuary as contains two ounces of the ſoap, unleſs his pain and provocation to make water be violent; in which caſe it will be proper to begin with about half this quantity, and to increaſe it as he can bear. The medicine ought alſo in this caſe to be dulcified in an extraordinary degree.

By this medicine, the doctor thinks the generation of gravel, and gravel-ſtones, may be entirely prevented. See STONE.

It is likewiſe recommended in diſorders of the ſtomach and bowels, ariſing from, or attended with, acidities there; and in gouty habits. The patient may, in many of theſe caſes, begin with ſuch a quantity every day as contains an ounce of ſoap, and afterwards increaſe or leſſen this quantity, as he finds occaſion.

LITHOPHAGI, of λιθος, *ſtone*, and φαγω, *to eat*, a name given to thoſe who are capable of eating and digeſting ſtones; inſtances of which are given by Boyle, Exp. Phil. p. ii.

eſſ. iii. p. 86. Bulwer, Artificial Changeling, p. 307. and Paulian, Dict. Phyſique, art. *Digeſtion.*

LITHOPHAGUS, or STONE-EATER, in *Natural Hiſtory.* Under this name Deſbois deſcribes a ſmall worm, which deſtroys and feeds upon ſtones. It is covered by a ſmall, very tender, and brittle ſhell, of aſh-grey and greeniſh colour. This ſhell is pierced at both extremities: the worm evacuates its excrements through one of the apertures, while the other ſerves for an outlet to the head and legs. The animal itſelf is blackiſh; its body is compoſed of rings with ſix feet, three at each ſide; each foot with two joints. Traces of this worm are, according to the ſame author, ſometimes ſeen in the layers of ſchiſtus. Its progreſſive motion is effected by its head, with which it works its way, while the remainder of its body reſts on its feet. It has four jaws, which ſerve the purpoſes of teeth; and from its mouth iſſues a thread, of which it conſtructs its ſhell. It is furniſhed with ten ſmall black eyes, five on each ſide, and diſpoſed in a curved line like a creſcent. This worm undergoes a metamorphoſis in its ſhell, but it is not yet known what new form it adopts. Deſbois adds, that more than forty worms have been ſeen to iſſue from out the chryſalis: their heads were black, the feet very diſtinct, and the body partly of a yellow and partly of a red colour. Latreille conjectures this to be the larva of an inſect belonging to the tinea tribe.

LITHOPHILA, in *Botany*, ſo called by Dr. Swartz, being derived from λιθου φιλο, *a lover of rocks*, or *ſtones*, for it is an inhabitant of barren, ſtony places. Swartz. Prod. 14. Ind. Occ. v. 1. 47. Schreb. 784. Willd. Sp. Pl. v. 1. 154. Mart. Mill. Dict. v. 3.—Claſs and order, *Diandria Monogynia.* Nat. Ord. *Caryophyllei*, Linn. *Caryophylleis affine*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of three lanceolate, acute leaves. *Cor.* Petals three, ovate-lanceolate, erect, meeting together, the length of the calyx-leaves. Nectary of two oppoſite leaves, ſmaller than the corolla, carinated, acute, erect, compreſſed. *Stam.* Filaments two, awl-ſhaped, erect, from the baſe of the germen, as long as the nectary; anthers roundiſh. *Piſt.* Germen ſuperior, roundiſh; ſtyle erect, equal in length to the ſtamens; ſtigma obtuſe, emarginate. *Peric.* two-celled? *Seeds* unknown.

Eſſ. Ch. Calyx of three leaves. Corolla of three petals. Nectary of two leaves.

1. L. *muſcoides.** Swartz. Ind. Occ. v. 1. 48. t. 1.—A native of rocks in the deſert iſland of Navaza, in the Weſtern ocean.—*Root* very firmly attached to the rocks. *Stems* numerous, branched, very ſhort, thickiſh. *Branches* ſet with withered, whitiſh ſcales. *Leaves* ſmall, almoſt ſeſſile, narrower and embracing the ſtem at their baſe, linear, obtuſe, channelled, ſpreading. *Flowers* crowded together, whitiſh, on axillary and terminal ſtalks; each flower the ſize of a ſmall pin's head. The whole plant is extremely minute, ſcarcely half an inch high, and the parts of fructification are ſo ſmall as to require a magnifying glaſs for examination. This is the only ſpecies known.

LITHOPHOSPHORUS, the ſtony ſubſtances deſcribed under this name, in the works of ancient mineralogiſts, belong partly to a variety of ſulphate of barytes (Bononian ſtone), partly to ſome varieties of fluor ſpar; the name being derived from the property they poſſeſs of giving out light when ſcratched, or thrown on burning coals.

LITHOPHYTA, in the Linnean ſyſtem of *Natural Hiſtory*, the fourth order of vermes or worms; being compoſite animals, affixed to, and fabricating a fixed calcareous baſe, called coral: this order contains 59 ſpecies under four genera; *viz.* the *tubipora*, or red tubular coral, *madrepora*, or brain-ſtones, *millepora*, and *cellipora*. See GORGONIA.

One of the moſt remarkable ſpecies of the ſmall lithophyta we have any where an account of, is that deſcribed by Mr. Lewenhoeck, though without any particular name, in the Philoſophical Tranſactions, N° 286. p. 1430.

LITHOPTERIS, STONE-FERN, in *Natural Hiſtory*, a name given by Mr. Lhuyd to ſome of the foſſile plants of the fern kind.

LITHOSPERMUM, in *Botany*, from λιθος, *a ſtone*, and σπερμα, *the ſeed*, alluding to the marble-like hardneſs and poliſh of that part. Linn. Gen. 74. Schreb. 99. Willd. Sp. Pl. v. 1. 751. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 213. Ait. Hort. Kew. ed 2. v. 1. 286. Juſſ. 130. Tourn. t. 55. Lamarck Illuſtr. t. 91. Gærtn. t. 67.—Claſs and order, *Pentandria Monogynia.* Nat. Ord. *Aſperifoliæ*, Linn. *Borragineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, oblong, erect, in five deep, awl-ſhaped, acute, keeled, permanent ſegments. *Cor.* of one petal, funnel-ſhaped, as long as the calyx; tube cylindrical; limb obtuſe, erect, cloven half way down into five ſegments; throat pervious. *Stam.* Filaments five, very ſhort; anthers oblong, in the mouth of the corolla. *Piſt.* Germens four; ſtyle central between them, thread-ſhaped, the length of the tube; ſtigma obtuſe, cloven. *Peric.* none, except the calyx become ſpreading, and lodging the ſeeds, which it exceeds in length, in its cavity. *Seeds* four, ovate, pointed, hard and ſmooth.

Obſ. L. *diſpermum* has an inflated calyx, and but two ſeeds, each, as in the others, of a ſingle cell.

Eſſ. Ch. Corolla funnel-ſhaped, its mouth pervious and naked. Calyx in five deep ſegments.

The genera of the order of *Aſperifoliæ* have been thought by ſome to have been diſtinguiſhed with too great minuteneſs by Linnæus. The character of the preſent chiefly differs from *Pulmonaria* in the deep diviſions of its calyx; which part, nevertheleſs, in ſome ſpecies of the latter, is very nearly as much divided. Willdenow has ſixteen ſpecies of *Lithoſpermum*, of which three are Britiſh, *officinale*, *arvenſe*, and *purpuro-cæruleum.* The *flowers* are generally blue or whitiſh, rarely yellow; the *habit* herbaceous, rarely in ſome degree ſhrubby, very hairy or briſtly; *root* often annual; *leaves* ſimple, undivided, entire, alternate, almoſt univerſally ſeſſile. The following examples may ſuffice.

L. *officinale.* Common Gromwell, Grey Mill, or Grey Millet. Linn. Sp. Pl. 189. Engl. Bot. t. 134.—Seeds even. Corolla ſcarce longer than the calyx. Leaves lanceolate, veiny, rather acute.—Native of waſte ground, where the ſoil is dry, gravelly, or chalky, in various parts of Europe, being perennial, and flowering in May. The whole *herb* is of a dull duſky green, hairy, about two feet high; the *leaves* paler beneath, the ſhort and copious hairs of their upper ſurface each ſpringing from a minute white poliſhed tubercle. *Flowers* ſmall, pale buff-coloured, in leafy ſpikes, which are at firſt recurved, then erect. The *ſeeds*, two of which only are uſually perfected in each calyx, are remarkable for their poliſhed pearly whiteneſs, though ſometimes tinged with brown. Their ſtony hardneſs has given occaſion to a report of their effervescing with vinegar, as if really calcareous, but this appears to be without foundation; as well as their ſuppoſed utility in calculous complaints, which ſeems to have ariſen from the ſame circumſtance; juſt as ſpotted or bliſtery vegetables were preſumed good for the lungs.

L. *arvenſe.* Corn Gromwell, or Baſtard Alkanet. Linn. Sp. Pl. 190. Engl. Bot. t. 123. Fl. Dan. t. 456.—

Seeds rugged. Corolla ſcarce longer than the calyx. Leaves obtuſe, without lateral veins.—Native of fields and waſte places, in a dry ſandy ſoil, throughout Europe. The *root* is annual, its bark affording a fine red ſtain, like Alkanet, with which the country girls, in the north of Sweden, are accuſed by Linnæus of ſtaining their cheeks. The *ſtem* is buſhy, ſpreading, hardly a foot high. *Corolla* white. *Seeds* brown, rugoſe.

L. *purpuro-cæruleum*. Creeping Purple Gromwell. Linn. Sp. Pl. 190. Engl. Bot. t. 117. Jacq. Auſtr. t. 14.—Seeds even. Corolla much longer than the calyx. Leaves lanceolate, acute, without lateral veins.—Native of buſhy waſte ground, in the more temperate climes of Europe, eſpecially where the ſoil is calcareous, flowering in May. With us it is eſteemed a rare plant. The *root* is perennial, black and creeping. *Stems* herbaceous, ſcarcely branched, while barren procumbent and rooting, otherwiſe erect, round, leafy, about a foot high, terminating in a forked leafy cluſter, of ſeveral handſome purple *flowers*, with a pale reddiſh tube. The *ſeeds* are often abortive. There are five blunt hairy ſwellings round the orifice of the tube, which, though they do not cloſe that part, render the generic character ſomewhat ambiguous. Such however are found in all the Britiſh ſpecies, and in ſome, though not all, of the exotic ones.

L. *fruticoſum*. Shrubby Gromwell. Linn. Sp. Pl. 190. (Anchuſa lignoſior monſpelienſium, flore violaceo; Barrel. Ic. t. 1168.)—Stem ſhrubby, erect. Leaves linear, hiſpid. Segments of the corolla ſlightly pointed; tube hairy.—This beautiful plant occurs on rocky expoſed hills and cliffs in the ſouth of France, Italy, and the Levant. Its ſhrubby buſhy *ſtem*, and copious roſemary-like leaves, diſtinguiſh the ſpecies. The *flowers* are of a moſt vivid blue.

L. *hiſpidulum*. Briſtly Woody Gromwell. Sm. Prodr. Fl. Græc. Sibth. v. 1. 114. Fl. Græc. ined. t. 162.—Stem ſhrubby, diffuſe. Leaves elliptic-oblong, obtuſe, hiſpid. Branches hoary.—Gathered by the late Profeſſor Sibthorp, on rocks in the iſle of Rhodes. Its *flowers* are nearly as beautiful as the laſt, but their ſegments are more rounded, and the throat more inflated, that part being, in both theſe, deſtitute of any marginal ſwellings or appendages. The preſent is not mentioned by Willdenow.

L. *orientale*. Yellow Perennial Gromwell. Linn. Syſt. Veg. ed. 14. 185. Willd. n. 9. Curt. Mag. t. 515. (Anchuſa orientalis; Linn. Sp. Pl. 191.)—Seeds rough with ſharp points. Spikes long, leafy. Leaves oblong, wavy.—Native of the Levant; hardy and perennial in our gardens, flowering in May and June, and diſtinguiſhed by its full-yellow *corolla*, whoſe ſegments are rounded, and orifice without ſwellings. The floral *leaves* are ſometimes heart-ſhaped, ſometimes ovate or lanceolate; thoſe of the ſtem oblong or lanceolate, wavy at the edges; all hairy.

Several peculiarly briſtly ſpecies of this genus were found and deſcribed by Forſkäll, which have been adopted by Vahl and Willdenow.

LITHOSPERMUM *Officinale*, ſeu *Milium Solis*, *Common Gromwell*, in the *Materia Medica*, is found in various parts of England, on a dry gravelly ſoil, and flowers in May and June. According to Haller, this plant poſſeſſes narcotic powers; but its ſeeds only have been medicinally employed. Theſe ſeeds have long excited the attention of naturaliſts, on account of their exquiſitely poliſhed ſurface, and ſtony hardneſs. The internal ſubſtance is ſofter, and ſeems to conſiſt of a farinaceous, ſweet, and oily matter, which becomes rancid on being long kept. The ſtony appearance of theſe ſeeds formerly ſuggeſted their efficacy in calculous and gravelly diſorders, to perſons whoſe judgment was influenced by ſuperſtitious and abſurd conceits. But though modern writers do not allow the lithontriptic character of the ſem. milii ſolis, yet they generally aſcribe to them a diuretic quality, a power of cleanſing the urinary paſſages, and of obviating ſtrangury, eſpecially when employed in the form of an emulſion; but Woodville obſerves, that the free uſe of any bland diluent would probably anſwer theſe purpoſes equally well. The abſorbent virtue aſcribed to theſe ſeeds is wholly groundleſs, being irreconcileable to the principles of chemiſtry. Woodv. Med. Bot.

LITHOSTROTA, among the *Ancients*, pavements made up of ſmall pieces of cut marble of different kinds and colour. See TESSELATED.

LITHOSTROTION, in *Natural Hiſtory*, the name of a ſpecies of foſſile coral, compoſed of a great number of long and ſlender columns, ſometimes round, ſometimes angular, jointed nicely to one another, and of a ſtarry or radiated ſurface at their tops. Theſe are found in conſiderable quantities in the northern and weſtern parts of this kingdom, ſometimes in ſingle, ſometimes in complex ſpecimens.

LITHOTOME, from λιθος and τεμνω, a name that has been given to a variety of cutting inſtruments, which have been employed for making an opening into the bladder, in order to extract the ſtone. The moſt celebrated of all is the lithotome caché of Frère Côme, of whoſe inſtrument and methods of operating we ſhall have to ſpeak in the following article.

LITHOTOMY, from λιθος, *a ſtone*, and τεμνω, *to cut*, ſignifies, in *Surgery*, the operation by which a ſtone is extracted from the bladder.

Surgical writers inform us, that urinary calculi admit of being extracted from three different ſituations, *viz.* from the kidney, the urethra, and the bladder. The queſtion, whether a ſtone ought ever to be cut out of the kidney, will have due conſideration given to it under the head NEPHROTOMY; and the removal of calculi from the urethra will be treated of in the article URETHRA. Our preſent obſervations will be confined to the ſtone in the bladder, a ſubject of infinite importance, whether we contemplate the ſeverity or frequency of the affliction; its incurableneſs by medicines, or the perils and difficulties of the operation for its relief; the numerous modes of cutting for the ſtone, or the nice judgment requiſite not only in the choice of a method, but alſo in the ſelection of inſtruments; the anatomical knowledge which the operator ought to poſſeſs; or, finally, that happy, though rare, combination of gentleneſs, dexterity, and reſolution, ſo eſſential in conſtituting a diſtinguiſhed and ſucceſsful lithotomiſt. We have heard of a Pott, who would finiſh the operation by four or five movements, and fill every ſpectator with admiration of his ſuperior ſkill. True ſkill, however, rather conſiſts in doing a thing as ſafely as poſſible, than with the utmoſt quickneſs. Now, if it be certain that lithotomy is more likely to be followed by the patient's recovery, when no manual roughneſs is exerciſed, rapid operating muſt be condemned by the judicious and diſcerning, however calculated it may be to excite the applauſe and admiration of the inexperienced ſtudent. Pott, we are informed, was remarkably ſucceſsful in his operations for the ſtone: but, it muſt be aſked, did he not loſe ſome of his patients? If he did,—great as his ſucceſs might be, we are juſtified in thinking that it would have been ſtill greater, had it been his cuſtom to aim at gentleneſs more than expedition. The example of Pott, therefore, is not to be imitated in this reſpect; and that he even acted in oppoſition to his own principles is fully proved by the following paſſage: "I cannot omit this opportunity of adding a few words on a ſubject, which appears to me highly deſerving of ſome notice, as its influence may be very extenſive, and very prejudicial: it is the falſe idea which the by-ſtanders at an operation generally have of chirurgic *dexterity;* to which word they annex no other idea than that of quickneſs. This has produced a moſt abſurd cuſtom of meaſuring the motion of a ſurgeon's hand, as jockeys do that of the feet of a horſe, *viz.* by a ſtop-watch; a practice which, though it may have been encouraged by operators themſelves, muſt have been productive of moſt miſchievous conſequences. *Tuté et celeriter* are both very proper characteriſtics of a good chirurgic operation: but *tuté* ſtands, as it ſhould do, in the firſt place; as the patient, who ſuffers the ſmalleſt injury from the hurry of his operator, has no recompence from the reputation which the latter obtains from the by-ſtanders. In moſt of the capital operations, unforeſeen circumſtances will ſometimes occur, and muſt be attended to; and he who, without giving unneceſſary pain from delay, finiſhes what he has to do in the moſt perfect manner, and the moſt likely to conduce to his patient's ſafety, is the beſt operator." (Pref. to Obſ. on Fiſt. Lachrymalis.) We ſhould not have premiſed theſe remarks, had we not often ſeen ſurgeons guilty of unwarrantable hurry and roughneſs in the performance of lithotomy; and did we not believe that the inflammation of the bladder and peritoneum, of which patients uſually die after the operation, may, in numerous inſtances, be imputed to ſuch a cauſe.

The ſtones, which are met with in the human bladder, are not all originally formed in this viſcus: many deſcend through the ureters from the kidnies; but yet it is not to be denied, that moſt of them are firſt produced in the bladder itſelf, by a ſpontaneous concretion of particular ſalts contained in the urine. It may be inquired, Is the exiſtence of a centre, round which the calculous materials are depoſited and arranged, abſolutely neceſſary to the formation of ſuch concretions? It is well known, that whenever an extraneous ſubſtance lodges in the bladder, it becomes the nucleus of a ſtone; but, on the other hand, the centre of many calculi preſents no particular appearance, nor any mark from which we can infer that they had any central ſubſtance, upon which they increaſed to their preſent ſize. Poſſibly, ſays Richerand, a clot of blood, or a piece of thickened mucus, may ſerve as their baſe, and yet, after a time, diſappear. However this may be, urinary calculi offer numerous differences in reſpect to their ſize, ſhape, number, denſity, compoſition, and the manner of their being contained in the bladder. Noſogr. Chir. tom. iii.

In ſome caſes, the bladder only contains one ſtone; in others, it includes ſeveral. In this laſt circumſtance, the calculi are always ſmaller; their diminiſhed ſize being in proportion to the greatneſs of their number. It has been eſtimated that, on the average, about three-fourths of calculous patients have only one ſtone in their bladder. Our own individual experience would make the proportion much higher, perhaps five or ſix out of every ſeven. Sometimes the bladder contains two calculi; but a larger number may occur from three to ſixty, or more. Their ſize varies from that of a bean to that of a cocoa nut. The muſeums of the Ecole de Médecine at Paris, and that of profeſſor Fourcroy, exhibit ſpecimens of calculi, which filled the whole cavity of the bladder. In the Philoſophical Tranſactions for 1809, ſir James Earle has deſcribed an enormous ſtone, which could not be extracted from the bladder; the attempt having been made in vain by Mr. Cline. Indeed the calculus filled almoſt the whole of the pelvis, and could not be taken out of the dead ſubject without conſiderable difficulty. The weight of this immenſe ſtone was forty-four ounces; its form elliptical, with a long axis of ſixteen, and a ſhorter one of fourteen inches. This, however, was an extraordinary caſe; and the average ſize of calculi, met with in the bladder, is from the bulk of a pigeon's to that of a hen's egg.

The varieties of ſhape are innumerable: moſt of the ſtones, however, which are found in the bladder, are oval, and more or leſs flattened. Their ſurface is ſometimes ſmooth and rounded; very often it is irregular and rough. Stones, ſtudded with aſperities, are frequently termed *mulberry calculi,* and that theſe muſt produce conſiderable irritation of the bladder, and a vaſt deal of pain, is a fact which requires no comment. We ſaw a ſtone extracted a few weeks ago, the outer ſurface of which was quite ſmooth and of a light colour; but on breaking a portion of it away, the inner part of the calculus preſented a granulated and dark brown appearance. The generality of ſtones taken from the human bladder are hard and reſiſting; but ſome are exceedingly friable, giving way to the ſlighteſt preſſure, and breaking into ſmall pieces, or even into a ſort of gritty matter.

The chemical compoſition of urinary calculi is far from being always the ſame. The learned inveſtigations of Wollaſton, Pearſon, Fourcroy, and Vauquelin, have diſcovered, that the materials may conſiſt of uric acid, urate of ammonia, phoſphate of lime, ammoniaco-magneſian phoſphate, oxalate of lime, ſilex, and a peculiar modification of animal matter. The baſis of theſe concretions was aſcertained by Scheele to be the uric acid. Other ſpecies were afterwards detected. Dr. Wollaſton, whoſe diſſertation was publiſhed in the Philoſophical Tranſactions two years before the memoir of Fourcroy and Vauquelin was read to the French National Inſtitute, anticipated nearly every thing which the French chemiſts announced as their own diſcoveries; and it is very remarkable (as profeſſor Murray has noticed), that although the experiments of Pearſon, publiſhed in the Philoſophical Tranſactions the year after Wollaſton's, are referred to in that memoir, not the ſlighteſt mention is made of the diſcoveries of this latter gentleman! As our department is ſurgical, and not chemical, we ſhall quit this ſubject with briefly ſtating, that Dr. Wollaſton has arranged urinary calculi into four ſpecies. 1ſt. The uric acid concretion. 2dly. The fuſible calculus, or phoſphate of ammonia and magneſia. 3dly. The mulberry calculus, or oxalate and phoſphate of lime. 4thly. The bone earth calculus, or that compoſed of the phoſphate of lime.

It will be with regret, that we ſhall preſently have to ſtate the little practical advantage hitherto derived from the knowledge of the chemical compoſition of urinary calculi.

Theſe concretions are uſually quite free and unconnected, ſo that the particular ſituation, which they occupy in the cavity of the bladder, is ſubject to change, being determined entirely by their own weight, or the contractions of the organ containing them. In ſome inſtances, however, they are adherent to the parietes of the bladder, and continue fixed in one place. Such adheſion may happen in three manners. 1. The ſtone may have been formed in a cul-de-ſac appendage, conſiſting of a protruſion of the lining of the bladder between the fibres of its muſcular coat; or, after being originally lodged in the common cavity of the bladder, it may have been forced into a pouch of this kind by ſubſequent contractions of this viſcus. 2. The ſtone may be lodged in that portion of the ureter which runs obliquely between the coats of the bladder. 3. Laſtly, the irregular ſurface of a calculus may be, as it were, implanted in the fungous granulations, which occaſionally ariſe from the inſide of the bladder, and, in this circumſtance, the ſtone can only be extracted by tearing its connection.

The calculi, which lie in a ſort of cul-de-ſac protruſion of the lining of the bladder, are often named *encyſted.* We believe that a ſtone, thus circumſtanced, is not likely to cauſe ſevere pain; the containing pouch becomes habituated to its preſence; and the ſenſible inſide of the bladder is not expoſed to any irritation or injury from it. We conceive it poſſible for ſome of the alleged diſſolutions of ſtones to have been caſes, in which the extraneous body became thus protruded, between the faſciculi of muſcular fibres, into a cyſt formed of the inner membrane of the bladder. A ſtone encyſted in this manner would, in all probability, neither require extraction, nor admit of it.

Blundering and baffled operators are generally eager to lay hold of any excuſe for their miſconduct, or ill ſucceſs. The adheſion of the ſtone has been frequently employed as a defence againſt cenſure, when the attempts to extract the foreign body have failed. Encyſted calculi, generally, cannot be touched with a ſound, and both on this account, and becauſe the ſymptoms are far more lenient than thoſe of a ſtone in the bladder, ſuch caſes do not demand the performance of lithotomy. A ſtone in the lower part of the ureter could not be touched with the ſound, and would be attended with effects different from thoſe of a calculus in the cavity of the bladder. Now, theſe are the only examples where the extraction of the ſtone would be impracticable on the ground of adheſion, and they are certainly inſtances in which an intelligent ſurgeon would never begin the attempt. But we aſſert with confidence, that when a calculus is fairly lodged in the cavity of the bladder, no adheſion can be a juſt excuſe, or reaſon, for its not being extracted. We muſt be convinced, with that eminent ſurgeon Le Dran, that an animated body, which ſubſiſts by a circulation of fluids, and another body, which owes its bulk entirely to an appoſition of matter, can never become one and the ſame by any kind of adherence, let it be ever ſo ſtrong. Le Dran made no doubt, that there were ſuch things as adherent ſtones, becauſe he had ſeen inſtances of them, but theſe adheſions ought not to have hindered the ſtone from being extracted, provided it could be laid hold of with the forceps. In 1730, this ſurgeon cut a lady, and extracted a ſtone, that weighed ſeven ounces and a half. One ſide of it was uneven, and in a manner entirely incruſted upon that part of the bladder which is connected with the rectum. This incruſtation was occaſioned by the inequalities of the ſtone, which had produced an excoriation of that part of the bladder upon which they preſſed, and, in conſequence thereof, a number of fleſhy or fungous excreſcences aroſe from the excoriated ſurface, and had lodged themſelves in the cavities of the ſtone. The adheſion was broken with hardly any pain. Le Dran, at ſubſequent periods, extracted from three patients ſtones, which adhered in the ſame manner. In 1715, he was preſent at an operation, performed by M. Marechal, when a ſtone was extracted, which was ſhaped like a calabaſh, or gourd, and brought out with it a fungus, that encircled the ſtone at its narroweſt part. As this fungous excreſcence paſſed round, and covered the middle of the ſtone, no new ſtrata could be formed in that part, but were made at the two extremities, which was the reaſon of its being ſo ſhaped; and the fungus fixed it ſo completely in the bladder, that it could not poſſibly change its ſituation. Traité des Operations de Chirurgie.

Of all animals, man is ſaid to be the moſt ſubject to urinary calculi. The human urine contains a particular acid, ſo little ſoluble, and ſo diſpoſed to produce concretions, that, frequent as the diſorder is, it is rather a matter of ſurpriſe, that it is not even more common. In warm countries, like Spain and Africa, as well as in nations much to the north, ſuch as Sweden, the diſeaſe is exceedingly rare. In temperate climates, it prevails the moſt in cold damp countries, like England and Holland; and, according to Richerand, it occurs in ſome of the provinces of France much more than in others, patients with the ſtone being more numerous in the northern, than the ſouthern departments of that empire.

Children and old people are more frequently afflicted than adults, and women are leſs expoſed to the diſorder than men.

Symptoms of a ſtone in the bladder.—A ſtone in the bladder occaſions pain, and derangement of the excretion of the urine; and when a ſuſpicion of the diſeaſe is excited by theſe ambiguous ſymptoms, it can only be confirmed by introducing an inſtrument, called a ſound, into the bladder. The pain produced by the preſence of a calculus in the bladder, has the particularity of always affecting, in a very remarkable manner, the extremity of the penis. The glans becomes the ſeat of an itching ſenſation, which daily increaſes in violence; and patients, eſpecially children, often get into the habit of pulling forwards the prepuce, in order to obtain relief. Hence, this part is frequently elongated in an extraordinary degree. This ſympathetic ſort of pain is more acute the larger the ſtone is, and the greater the irregularity of its ſurface. When the bladder is full of urine, the pain is not inſupportable; but juſt at the period when the diſcharge of that fluid is finiſhed, the ſuffering becomes intolerable, becauſe, at this inſtant, the bladder contracts, and embraces the foreign body with conſiderable force. All rough exerciſes augment the pain; but walking over an uneven country, riding on horſeback, and the jolting of a carriage particularly, have ſuch an effect. When the patient is ſubjected to theſe exerciſes, he not unfrequently diſcharges a few drops of blood from the urethra.

The deſire to make water comes on very often, and the urine, as it flows, is attended with a ſenſation of heat, which changes into a burning kind of pain at the extremity of the penis. The ſtream of water is ſometimes interrupted all on a ſudden. The patient vainly endeavours to continue the evacuation; he applies his hand to the perineum; he moves about, lies down, or, in ſome way or another, alters his poſture, and the urine then begins to run again. The moveableneſs of the ſtone makes it every now and then fall againſt the orifice of the neck of the bladder, and thus prevent, for a time, the exit of the urine.

The inceſſant irritation, produced by the preſence of the calculus, extends to the rectum; the patient is continually teazed with an inclination to go to ſtool, and the efforts, which his imaginary want cauſes him to make, bring on, in many inſtances, hemorrhoidal complaints, or even a prolapſus ani.

In the courſe of time, the pain becomes more acute and unremitting. The ſtone increaſes in ſize, and, by continually preſſing upon the inferior part of the bladder, makes the patient experience a moſt painful ſenſe of weight about the rectum. The evacuation of the urine is attended with more and more difficulty. The parietes of the bladder inflame, and are rendered thicker; its inner ſurface ulcerates; the urine becomes blended with matter and blood; a ſlow ſort of fever occurs; and the patient, after lingering a great while in miſery and pain, falls a victim to the diſorder. On opening the body after death, the bladder is found contracted, and its coats thickened, indurated, and more injected with blood, than in the healthy ſtate.

The fatal termination, to which theſe caſes tend, when unrelieved, is ſubject to conſiderable variety. Some patients have been known to live with a ſtone in their bladder ten, twenty, and even thirty years, without the pain being ſo ſevere as to incline them to ſubmit to lithotomy. Richerand moreover aſſures us, that calculi, of very large ſize, and irregular ſurfaces, have ſometimes given riſe to no ſymptoms, by which their preſence could be ſuſpected. This author tells us, that, as he was once practiſing operations on the dead ſubject in the Hôpital de la Charité, he extracted an enormous mulberry calculus from the bladder of a patient who had died of ſome other diſeaſe, and who, while living, had betrayed no complaints, indicating that he was afflicted with the ſtone. This calculus, which was compoſed of the oxalate of lime, was exceedingly heavy, and by its weight, darkneſs of colour, and the manner in which its ſurface was ſtudded with obtuſe points, bore a great reſemblance to a ſcoria of iron. It is preſerved in Fourcroy's muſeum, where it was depoſited by Boyer.

The ſymptoms of a ſtone in the bladder are ſo fallacious and equivocal, that every prudent ſurgeon avoids delivering a poſitive opinion, before he has ſounded the patient. Certain complaints may make him ſuſpect the nature of the caſe; but he muſt never preſume to be certain, until he has actually touched and felt the ſtone, by means of a metallic inſtrument, paſſed through the urethra into the bladder. The general ſymptoms of a ſtone in the bladder are not peculiar to this diſorder; they belong to ſeveral other affections, for which the practitioner may be conſulted. An enlarged proſtate gland produces many effects, like thoſe of a ſtone in the bladder. There is this difference, however, riding in a carriage, or on horſeback, does not increaſe the grievances when the proſtate is affected; but it does ſo, in an intolerable degree, in caſes of ſtone. It alſo generally happens, that the fits of ſtone come on at intervals, whereas the pain from a diſeaſed proſtate is neither ſo unequal, nor ſo acute.

At this preſent time, (September 1811,) there is a man in St. Bartholomew's hoſpital who ſuffers many of the complaints uſually attending a ſtone in the bladder; he has been ſounded, but no calculus can be diſcovered: and it is now aſcertained that his ſymptoms are dependent upon a contraction ſituated ſome diſtance up the rectum. The ſtricture is ſo conſiderable, that the feces can only paſs in a liquid form, and the introduction of bougies above a ſmall ſize is quite obſtructed.

Who would ſuppoſe that ſymptoms, exactly ſimilar to thoſe of a ſtone in the bladder, could proceed from the venereal diſeaſe, and be cured by mercurial treatment? Yet, ſuch a fact have we recorded by Richerand, now an eminent ſurgeon at Paris. See Noſographie Chirurgicale, tom. iii. p. 506, edit. 2.

Nothing, therefore, except ſounding the patient, will give the ſurgeon certain information of the preſence of a calculus in the bladder. The ſymptoms which prevail may excite ſtrong ſuſpicions of the nature of the caſe; but ſince they may proceed from ſo many other different cauſes, they are not alone a ſufficient warrant for venturing on the performance of lithotomy. When the ſurgeon undertakes this important operation, he muſt know with certainty that there is a ſtone in the bladder, and ſuch poſitive knowledge can only be acquired by actually feeling and hearing the ſteel inſtrument, called a ſound, ſtrike againſt the foreign body. Nay, further, as the ſtone may be in the bladder to day, but be protruded to morrow on the outſide of the muſcular coat of this organ, ſo as to become as it were encyſted and incapable of extraction, "it is an invariable maxim among all prudent ſurgeons never to begin the operation of lithotomy unleſs they can clearly and diſtinctly perceive the ſtone with the ſound, or at leaſt with the ſtaff at the time when the patient is brought forth to be operated upon." If the calculus cannot be plainly felt at this period, the operation is not juſtifiable. The importance of this precept cannot be too highly appreciated by every practitioner who values either his patient's welfare or his own reputation; for were a different line of conduct purſued, an opening might be made into the bladder, no ſtone be found, and, unfortunately, the patient loſe his life from the operation, which, however well executed, is never free from a ſerious degree of danger.

The method of ſounding will be deſcribed in a future volume of this Cyclopædia. See SOUNDING.

The ſtone in the bladder is a diſorder that is to be regarded as more grievous the longer it has exiſted, and the older and more debilitated the patient is. The caſe is particularly afflicting when the ſevere pain in the kidnies renders it not unlikely that there may be at the ſame time other calculi in the ſubſtance of theſe organs.

A ſtone is ſeldom known to be in the bladder until it is too large to paſs out through the urethra. Should a very ſmall one be detected, we are recommended to try the effect of introducing a large ſound or bougie, making the patient drink abundantly of ſome diuretic liquor, and deſiring him firſt to retain his urine, and then expel it as forcibly as poſſible, at the ſame time that the ſound or bougie is withdrawn. In this manner, it is conceived, the ſtream of the urine might ſometimes carry the calculus outward. Deſault had it in contemplation to adapt the port-crayon pincers, invented for the urethra by Mr. Hunter, to a common catheter, for the purpoſe of taking ſmall calculi out of the bladder. This project, however, would be attended with much difficulty, and the ſides of the bladder would be liable to laceration in conſequence of becoming pinched. Inſtruments made on this principle, however, are ſometimes ſucceſsfully employed for taking ſmall ſtones out of the urethra.

Diſſolution of ſtones in the bladder.—The poſſibility of diſſolving ſtones in the bladder was a thing believed for a very long ſpace of time, and even at the preſent day is a ſcheme not altogether abandoned. The diſſolution has been attempted both by internal medicines, and by certain fluids injected into the bladder.

The knowledge of the compoſition of urinary calculi at once appriſes us that, as they conſiſt of very different materials in different caſes, the ſame ſolvent cannot be applicable to all of them.

It is obſerved by Murray, one of the learned profeſſors of chemiſtry at Edinburgh, that long experience has ſufficiently eſtabliſhed the advantage derived in calculous affections from the uſe of alkaline remedies; and as the calculi, compoſed of uric acid, are thoſe which appear to be moſt abundant, it is ſuppoſed to be from the chemical action they exert upon it that the benefit is derived. Where the pure alkali is uſed, a real ſolvent power may be exerted; and it has been proved that the alkali is ſecreted by the kidnies, ſo as to render the urine ſenſibly alkaline, and even capable of acting on the calculus out of the body. Yet the ſolvent power is very inconſiderable, and the remedy at the ſame time proves ſo irritating, when taken to any conſiderable extent, that the ſolution of a calculus, even of ſmall ſize, can perhaps be ſcarcely expected. The pain and irritation which attend the diſeaſe, however, are conſiderably alleviated by their habitual uſe, and this even when the alkali is ſaturated, or ſuper-ſaturated with carbonic acid, a circumſtance with regard to which there appears ſome difficulty in giving an explanation, ſince the alkalies in this ſtate have been ſuppoſed not to act on the uric acid. But, from the experiments of Dr. Egan (Philoſ. Magaz. vol. 23 and 24), this appears to be a miſtake; though the relief obtained from the uſe of theſe may alſo be in part derived from the ſaturation of the other acid, whether phoſphoric or acetic, which is likewiſe ſecreted; the urine is thus rendered leſs irritating, and the tendency to a depoſition of uric acid diminiſhed, all acids haſtening the precipitation of this acid from the urine. It has accordingly been found, that under the uſe of alkaline remedies, the ſediment of uric acid from the urine, ſo often abundant in caſes of calculus, rapidly diminiſhes. The increaſe of the concretion is thus prevented, and the principal cauſe of irritation removed.

So far, therefore, profeſſor Murray acknowledges that the alkalies may act as palliatives; but he contends, that it muſt be very doubtful if they can be given to ſuch an extent as to exert an actual ſolvent power. Beſides, there is an effect which may attend their continued uſe, eſpecially in large doſes. It has been remarked by Mr. Brande, that the phoſphates of lime and magneſia are held in ſolution in urine, chiefly by its exceſs of acid; if this be ſaturated, therefore, by the uſe of an alkali, although the depoſit of uric acid may be checked, that of the phoſphates will be favoured, and it appears that it is principally from a depoſition of theſe that a calculus in the bladder increaſes in ſize. Some caſes, adduced by Mr. Home, appear to ſupport this concluſion.

Lime, under the form of lime-water, has been employed as a ſolvent. The experiments of Dr. Egan have ſhewn, that lime-water acts with more energy than an alkaline ſolution of ſimilar ſtrength in deſtroying the aggregation of urinary concretions, and Murray found the ſame thing. The lime probably operates more upon the albumen or animal matter, which appears to ſerve as the cement or connecting ſubſtance, than upon the uric acid; and Murray thinks that in endeavouring to diſcover ſolvents for theſe concretions, our views ought perhaps rather to be directed to this operation than to the effect on the ſaline matter. If, ſays he, lime, when received into the ſtomach under the form of lime-water, can be ſecreted by the kidnies, as the alkalies unqueſtionably are, it would appear to be ſuperior to them as a ſolvent. But when we conſider the ſparing ſolubility of lime, and the ſmall quantity of it therefore that can be brought to the kidnies, the poſſibility of its ſecretion may be doubted. Mr. Brande has even ſuppoſed that, were it ſecreted, it would rather prove hurtful, by forming an inſoluble compound with the phoſphoric or carbonic acids, which are always contained in the urine. Murray owns this to be poſſible; but he argues that if the concretion of theſe ſubſtances into a calculus is owing principally to the action of the animal matter, ſince this muſt be prevented, any depoſit would be diſcharged, and perhaps the aggregation of an exiſting concretion be deſtroyed. Under this view, Murray thinks that the proper practice would be the exhibition of alkali and lime together, the former neutralizing the exceſs of acid in the urine, and allowing the latter to exert its power; and it deſerves to be remarked, that the celebrated Stephens's remedies are a combination of this kind. Calculi, compoſed of oxalate of lime, phoſphate of lime, or phoſphate of magneſia and ammonia, not being ſoluble by alkalies, the object has been attempted by the action of weak acids, like that of lemons. It is queſtionable, however, whether any acid can be given ſo as to communicate to the urine a ſolvent power. Beſides, though an acid were to remove the phoſphates, or at leaſt prevent their depoſition, it might promote the formation of uric acid concretions. If, however, the lime-water and alkalies, by operating on the animal matter of calculi, tend to deſtroy their aggregation, theſe remedies may prove ſomewhat uſeful in all the varieties of ſtone.' See Murray's Syſtem of Chemiſtry, vol. iv. p. 651, et ſeq.

Setting aſide all chemical reaſoning, we are ſorry to be obliged to confeſs that practice does not juſtify any ſtrong hopes of the ſufficient efficacy of internal medicines to diſſolve ſtones in the bladder. But though lithontriptics are not equal to this effect, they certainly aſſuage the ſeverity of the ſymptoms, which is a benefit of infinite importance to the afflicted.

Medicines conveyed into the ſtomach having failed to diſſolve urinary calculi, various practitioners have placed conſiderable expectation in the plan of introducing a ſolvent injection through a catheter directly into the bladder. It will be ſeen, from the article CATHETER in this work, that the ancients knew how to introduce fluids into the bladder many centuries before Mr. J. Foot publiſhed upon the "Veſicæ Lotura." Fourcroy and Vauquelin aſcertained, that a ley of potaſſa or ſoda, not too ſtrong to be ſwallowed, ſoftens and diſſolves ſmall calculi, compoſed of the uric acid and urate of ammonia, when they are left in the liquid a few days. They have proved that a beverage, merely acidulated with nitric or muriatic acid, diſſolves with ſtill greater quickneſs calculi formed of the phoſphate of lime, and of the ammoniaco-magneſian phoſphate. They have made out that calculi compoſed of the oxalate of lime, which are the moſt difficult of ſolution, may be ſoftened and almoſt quite diſſolved in nitric acid, greatly diluted, provided they are kept in the mixture a ſufficient time. We know then liquids that will diſſolve calculi of various compoſitions; but much difficulty occurs in employing them effectually in practice. For although we can eaſily inject them into the cavity of the bladder, this organ is ſo extremely tender and irritable, that it cannot bear the contact of any fluid, except that which it is deſtined by nature to contain, and the action of ſuch liquids upon it as would be neceſſary to diſſolve a ſtone in its cavity would not fail to produce ſufferings which no man could endure, and the moſt dangerous and fatal effects on the bladder itſelf. Another objection to this experiment is the ignorance in which the practitioner is with regard to the chemical compoſition of calculi before their extraction, and of courſe the impoſſibility of knowing what ſolvent ought to be injected. Upon this reaſon, however, it is unneceſſary to lay much ſtreſs; for were the previous more weighty objection done away, the latter difficulty might perhaps be obviated.

Deſirable, therefore, as an effectual lithontriptic is, as it would be the means of freeing the afflicted from the terrible ſufferings occaſioned by a ſtone in the bladder, and of removing all occaſion for a painful and hazardous operation, it is a melancholy truth that, notwithſtanding every expectation, ariſing either from chemical reaſoning, from quackiſh boaſtings, or from the palliation and temporary relief really obtained, we have no practicable means of diſſolving a ſtone in the living bladder. Until this grand diſcovery is made, lithotomy will ever be an indiſpenſable operation, and the views of enlightened ſurgeons ſhould ſtill be directed to render it as free as poſſible from pain and dangerous conſequences.

We ſhall now endeavour to give an impartial deſcription of the principal methods of cutting for the ſtone, beginning with ſuch as are moſt ancient, and concluding with thoſe which have been very recently ſuggeſted.

Of the Apparatus minor, Methodus Celſiana ; or cutting on the gripe.—The operation which we are about to explain is by far the oldeſt ſpecies of lithotomy, its antiquity extending back to time immemorial. Although we are indebted to the immortal Celſus for the firſt deſcription of it, he was in all probability not the original inventor. We learn from hiſtory, that Hippocrates made his pupils take an oath that they would never attempt to cut for the ſtone ; and, according to Florus, the Latin hiſtorian, the ſon of Alexander, king of Syria, periſhed, when about ten years of age, in conſequence of this operation, which had been villainouſly undertaken, though there was no ſtone in the bladder. It is plain then, that, long before the time of Celſus, the ancients were acquainted with ſome mode of lithotomy, which we may infer was what is now called the apparatus minor. This laſt appellation, deduced from the ſmall number of inſtruments required, was not employed till the commencement of the ſixteenth century, the period when another method, named the apparatus major, had its riſe. The phraſe of "cutting on the gripe," came into uſe in conſequence of the ſurgeon having to cut upon the ſtone, while he graſped it, with his fingers introduced within the rectum.

The manner of doing the operation is this. You firſt introduce the fore finger and middle finger of the left hand, dipped in oil, up the anus, and preſſing ſoftly with your right hand above the os pubis, endeavour to bring the ſtone towards the neck of the bladder ; then making an inciſion on the left ſide of the perineum, above the anus, directly upon the ſtone, you turn it out through the wound, either with your fingers or a ſcoop. Sharp on the Operations, chap. 18.

Many objections have been urged againſt this method by ſurgical authors.

1. In the firſt place it is not applicable to adults, as, in ſuch patients, it would ſeldom be found poſſible to fix the ſtone by the fingers introduced within the rectum. Celſus confined the operation to ſubjects between the ages of nine and fourteen, which is rather extraordinary, as it is more eaſy of performance the younger the child is, though certainly it hardly admits of being done at all after the patient is more than fourteen.

2. The ſame parts are not always cut, as this depends very much upon the degree of force with which the ſtone is made to project in the perineum, and the leaſt inclination to one ſide or the other muſt alſo make a conſiderable difference. When the inciſion is favourably executed, the parts cut are nearly the ſame as thoſe divided in the modern and moſt approved mode of operating. But as the operator always cuts directly on the projecting ſtone, the parts expoſed to the knife muſt vary in different caſes for the reaſons already alleged ; and the records of ſurgery prove, that in performing the apparatus minor, the urethra may be quite detached from the proſtate, or the veſicula ſeminalis and vas deferens be injured.

3. The neck of the bladder muſt ſuffer very much from rough ſtones, when conſiderable force is exerted in preſſing them towards the perineum. That this is not mere conjecture, is confirmed by the obſervations of Celſus, from whoſe account it plainly appears that, in his time, many actually died from the violence done to the bladder, in endeavouring to bring the ſtone forwards, though the operators failed in their attempt, and the patients were not cut. Fabricius Hildanus was well acquainted with all the uncertainty of cutting on the gripe, and he endeavoured to improve the method by introducing a ſtaff through the urethra into the bladder, ſo that the operator might avail himſelf of the guidance of this inſtrument in making the requiſite opening for the extraction of the ſtone. Fabricius brought the ſtone into the neck of the bladder with his fingers, which were paſſed up the rectum, juſt as Celſus deſcribes, and then, guided by the ſtaff, made ſuch a diviſion of the proſtate and neck of the bladder, as ſufficed for the paſſage of the calculus outward. The extraction was accompliſhed with a ſort of hook.

The apparatus minor, done in this manner, is by no means an ineligible operation for young male children, when the ſurgeon can eaſily graſp the ſtone with his fingers, from within the rectum. We do not mean to ſay it is raſh to make an inciſion into the bladder with a common ſcalpel, guided by a ſtaff, even though the ſtone cannot be fixed with the fingers, only the operation would then not be that of "cutting on the gripe," to which, at preſent, our remarks are limited. We agree entirely with Mr. John Bell, who, in commending the improved Celſian method, as practiſed by Fabricius, takes occaſion to remark, that you cut upon the ſtone, and of courſe make, with perfect ſecurity, an inciſion exactly proportioned to its ſize. There is no difficult nor dangerous diſſection ; no gorget, nor other dangerous inſtrument, thruſt into the bladder, with the riſk of its paſſing between that and the rectum ; you are performing, expreſsly, the lateral inciſion of Raw and Cheſelden in the moſt ſimple and favourable way. John Bell's Principles of Surgery, vol. ii.

Of the Apparatus major, or *Sectio Mariana*.—This method of cutting for the ſtone was named *Apparatus major*, from the great number of inſtruments uſed in the operation ; and *Sectio Mariana* from one Marianus, who publiſhed the firſt deſcription of it. Johannis de Romanis, a ſurgeon at Cremona, was the inventor about the year 1523, or 1525, though the exact period is very uncertain. Marianus was the ſcholar of Romanis, and having learned his maſter's art of operating, printed an account of it in Latin. The date of this treatiſe ſeems rather undetermined, Douglas making it 1522, Sharp 1524, and Sabatier a period ſubſequent to 1540.

Experience has repeatedly proved, that, in conſequence of the ſhortneſs and dilatable nature of the female urethra, calculi of conſiderable ſize may be extracted from women without employing any cutting inſtruments at all. The paſſage may be gradually dilated, ſo as to allow the forceps to be introduced into the bladder, and the ſtone taken hold of, and extracted. The adaptation of this plan to male patients was the principal object of the Marian operation. With this view, an inciſion was made into the urethra at the bulb. That part of the canal which was ſituated between the wound and the neck of the bladder, being ſhort and ſomewhat ſtraight, was thought to bear a reſemblance to the female urethra. Inſtruments were therefore paſſed into the opening, for the purpoſe of dilating ſuch portion of the urethra, ſufficiently to let the forceps be introduced, and the ſtone extracted. It was never recollected that the male urethra, where it is ſurrounded by the proſtate gland, could not rightly be compared with the meatus urinarius of the female, ſince it was totally incapable of being dilated in a degree at all adequate to the objects in view. Hence moſt dreadful injury was done to the parts, which, inſtead of yielding, were torn and contuſed in a manner ſhocking to relate.

There were various modes of executing this barbarous operation ; the following particulars, we preſume, will at once ſatiſfy the curioſity of the profeſſional reader, and make him for ever abhor a method that is ſo repugnant to the principles of good ſurgery, and the dictates of humanity and common ſenſe.

The patient was bound in the poſition uſually adopted in the more modern methods of cutting for the ſtone. After an opening had been made into the urethra, cloſe behind the bulb, much in the ſame way as is practiſed in the performance of the lateral operation, the ſurgeon uſed to introduce into the bladder, along the groove of the ſtaff, an inſtrument reſembling a ſtrong iron probe, and called a male conductor. The ſtaff was then taken out of the urethra, and the female, or grooved conductor, guided along the male one into the bladder. By means of theſe two implements, endeavours were next made to dilate the undivided portion of the urethra, and the neck of the bladder, ſufficiently to enable the operator to introduce the forceps. After much time ſpent in ſtretching the parts, the forceps were paſſed into the cavity of the bladder, and the ſtone was drawn out, though, in general, not without conſiderable force and violence. Sometimes the dilatation was attempted with a blunt gorget; ſometimes by expanding the blades of the forceps. Many operators uſed different inſtruments for the purpoſe, called dilators. Franco, Tollet, the Collots, and Alghiſi, employed them.

When we reflect that, in this method, the proſtatic portion of the urethra was left undivided, a part which is very incapable of much dilatation, we muſt know that the opening through which the forceps was introduced, and the ſtone taken out, was not formed by the elaſtic yielding of the parts; but by an actual laceration of them, attended with an immenſe deal of contuſion and violence. In what a degree ſuch miſchief muſt have taken place in caſes where the ſtone was of large ſize, is eaſily conceivable. We cannot wonder, therefore, at the ſevere, and frequently fatal, conſequences of ſo barbarous an operation. The patients very often periſhed of inflammation of the bladder and abdominal viſcera. An extenſive effuſion of blood in the ſcrotum, abſceſſes and fiſtulæ in perineo, incontinence of urine, and impotency, were alſo common conſequences. With theſe facts before us, we muſt feel ſurpriſe that the operation of Marianus ſhould have been practiſed for the ſpace of two hundred years, by ſome of the moſt diſtinguiſhed ſurgeons in Europe, as Paré, Le Dran, Le Cat, Mery, Morand, Maréchal, Raw, &c.

The foregoing account will ſerve to convey a general notion of the apparatus major, ſo famous a ſubject in the hiſtory of lithotomy; but ſuch readers as wiſh to be acquainted with all the different modes in which it was practiſed by the old ſurgeons, ought to conſult De la Médecine Opératoire, par Sabatier, tom. ii.; and the Principles of Surgery, by Mr. John Bell, vol. ii. Very clear and more conciſe deſcriptions of the apparatus major may be found in Sharp's Treatiſe on the Operations, or in Bertrandi's Traité des Opérations.

Apparatus altus.—This is the technical name given to the method in which the ſtone is extracted from the bladder, through an inciſion practiſed in the fundus of this organ from above the pubes. The inventor of this mode of cutting for the ſtone was Pierre Franco, a ſurgeon at Tourrières, in Provence. He was led to attempt the operation, from having under his care a child with a calculus, that could not be brought towards the perineum on account of its magnitude. Although the little patient ſuffered much indiſpoſition afterwards, the wound healed, and a perfect recovery followed. The proſperous event of this caſe, it ſeems, was not enough to convince Franco, that wounds of the bladder were leſs perilous than he apprehended them to be, and at the ſame time that he details the particulars of the plan he purſued, he cautions us not to imitate him. See Traité des Hernies, Lyon, 1561.

Doubtleſs, the advice delivered by Franco intimidated his contemporaries; for we find no notice taken of the apparatus altus again till 1597, when this plan of operating was recommended by Roſſetti, a well-informed and judicious phyſician, in a work entitled "Partus Cæſarius." This author repreſents it as the beſt and ſafeſt mode of cutting for the ſtone; but though he had clear ideas of the poſſibility of the method, his obſervations are not ſupported by any actual experience of his own. Afterwards, the operation was at firſt reprobated, and then adopted by Fabricius Hildanus, in caſes where the ſtone was of conſiderable ſize. It was commended by Riolan in his remarks upon the anatomy of Veſlingius; and Simon Pietre, a phyſician at Paris, wrote a memoir in favour of the operation in the year 1635. Since this period, the apparatus altus is mentioned by numerous writers, though few ſurgeons ventured to perform it. However, it is ſaid to have been practiſed by Bonnet, an old ſurgeon of the Hôtel-Dieu. At length the faculty of Paris recommended the parliament to authoriſe ſome additional experiments in regard to the apparatus altus, and Francis Collet was appointed to make the requiſite trials of the operation. The reſult was, that, in his opinion, the method was attended with great danger, and, conſequently, the practice in France was prohibited.

The apparatus altus, however, was not every where abandoned. Proby, a ſurgeon at Dublin, practiſed it for the purpoſe of extracting from the bladder of a young woman a long pin, covered with a ſtony incruſtation, which he was unable to get out through the urethra. (See Phil. Tranſ. for 1700.) Groenvelt, a Dutchman, who, in 1710, publiſhed a treatiſe on lithotomy in Engliſh, ſays, that he was under the neceſſity of removing a ſtone from the bladder by cutting above the os pubis. At length, in 1718, Dr. Douglas wrote a diſſertation in praiſe of this method of operating, which was ſoon afterwards put to the teſt of experiment by his brother, the ſurgeon, who was imitated by ſeveral Engliſh and German practitioners. In conſequence of theſe proceedings, the operation was again revived in France, and it was practiſed at St. Germain-en-Laye by Berryer, a ſurgeon of that town, and by S. F. Morand, at the Hôtel des Invalides. The latter attempt proved unſucceſsful. An account of both theſe caſes was publiſhed by Morand in 1727. The operation was afterwards much on the decline in France, and probably would have been totally given up, had not a new method of performing it been propoſed by Frère Côme. See Nouvelle Methode d'extraire la Pierre de la Veſſie Urinaire par deſſus le Pubis, à Paris, 1779.

In the apparatus altus, the deſign of the ſurgeon is to make an opening into the anterior part of the bladder above the os pubis. The patient is to be placed upon a table, or bed of ſuitable height, with his legs reaching over the edge and reſting upon a ſtool. Two aſſiſtants are to keep the patient's body and arms ſteady, while two others take hold of his thighs. The patient's trunk ſhould be ſomewhat bent forwards, in order to relax the abdominal muſcles; but it is highly neceſſary for the pelvis to be rather more raiſed than the cheſt, ſo that the inteſtines may not gravitate towards the bladder, and by depreſſing this viſcus, make it more difficult to be got at. Beſides, raiſing the pelvis above the level of the thorax prevents the ſtone from falling towards the neck of the bladder, from which ſituation the extraction would be leſs eaſy.

The operation has been executed in ſeveral ways.

The moſt ancient mode was that of cutting directly upon the ſtone, which was puſhed upwards and forwards, towards the lower and front part of the abdomen, by two fingers introduced into the rectum. Franco operated in this manner, and he was imitated by Bonnet, Heiſter, &c. While an aſſiſtant puſhes the ſtone upward, the ſurgeon is to make an inciſion through the ſkin juſt above the os pubis, and through the lower portion of the linea alba: he is then to puncture the bladder, enlarge the opening from above downwards with a probe-pointed crooked biſtoury, and, laſtly, take out the ſtone with a pair of forceps.

Roſſetti was the inventor of a particular method. In the apparatus altus, it is an object of the greateſt conſequence to make an opening into the bladder without wounding the peritoneum. Hence Roſſetti adopted the plan of diſtending the bladder with warm water, which was injected through a catheter placed in the urethra, and thus made the viſcus riſe to a convenient height above the pubes. The fluid was injected in the moſt ſlow and gradual manner, in order that it might give as little pain and uneaſineſs as poſſible. The quantity introduced was, in general, from eight to ſixteen ounces. Some authors object to an injection, and recommend the patient to retain his water till the requiſite diſtention of the bladder has taken place. When this receptacle had been filled, the catheter was withdrawn, and the fluid kept from eſcaping by an aſſiſtant, who compreſſed the urethra. The integuments and linea alba were then cut, as in Franco's method. A puncture was next made in the bladder with a biſtoury, having its edge turned towards the pubes; and the ſurgeon with his left index finger, which was directly paſſed into the opening, kept the bladder from deſcending, while he finiſhed the inciſion of that viſcus, by cutting from above downwards below the os pubis. The bladder was ſtill kept up with the index finger, until the ſtone was extracted with the forceps. In order to be ſure of having the bladder diſtended, and to be able to introduce more injection if neceſſary, Mr. Middleton uſed to keep the catheter in the urethra till the inciſions were completed. On the other hand, Douglas was in the habit of cutting down to the bladder before he introduced the catheter.

The apparatus altus has been objected to as unadapted to perſons who are either inclined to be fat, or whoſe bladders are not capacious. Unfortunately, in the generality of ſtone-patients, the bladder is much contracted. The introduction of the injection has likewiſe been found a painful and uncertain proceeding; for, very often, a ſufficient quantity could not be got into the bladder, ſo that in operating there was ſome riſk of wounding the peritoneum. The method has alſo been accuſed of frequently giving riſe to an extravaſation of urine, and ſloughing and abſceſſes in the pelvis, in conſequence of the greater facility with which that fluid eſcapes through the wound of the bladder than through the urethra. Theſe unpleaſant events have been ſaid to take place the more eaſily, as when the bladder contracts, it deſcends behind the os pubis, and the wound in it no longer continues oppoſite to that in the linea alba and integuments. Keeping a catheter in the bladder, or the patient in an horizontal poſture, has not, it is ſaid, availed in preventing the frequency or fatality of ſuch miſchief.

However, Frère Côme's method of performing the apparatus altus, which we ſhall hereafter notice, is repreſented by the French ſurgeons as being free from the preceding inconveniences. When the account of this form of the apparatus altus has been read, we entertain little doubt that the operation will appear, to all good judges, to have merit. Frère Côme is ſaid to have cut nearly a hundred patients, in the manner alluded to, with almoſt uninterrupted ſucceſs. The plan has the advantage of enabling a ſurgeon to extract larger ſtones than can be taken out of the bladder by any other method, as the inciſion may be enlarged in proportion to their ſize, and the bladder is here more yielding than in the vicinity of the proſtate gland. Nor is the paſſage of a large ſtone here reſiſted by any bony obſtacles, as in other modes of operating. See Sabatier's Médécine Operatoire, tom. ii. p. 51.

It muſt be confeſſed, that ſome difficulty might ariſe in caſe the ſtone were to break, as the fragments could not be ſo eaſily taken out as in other methods. We are to remember, however, that this accident is leſs likely to happen, becauſe the parts through which the calculus has to paſs are all ſoft and yielding. Were it to take place, the larger pieces of the calculus might be extracted by means of proper forceps, and the ſmaller ones would be carried out with the urine through the tube in the perineum.

This method, againſt which the records of ſurgery appear to adduce no ſerious objections, founded on as poſitive experience, has been entirely abandoned. Want of ſimplicity is alleged againſt it; but we think without much reaſon, for the operation, as will be ſeen from the deſcription, is not difficult; nor is the number of inſtruments immoderate. If, what Richter mentions be true, that Frère Côme cut nearly a hundred patients in this way with almoſt invariable ſucceſs, the juſtification of further trials cannot be doubted. The method, as modified by Deſchamps, who, inſtead of cutting the perineum, perforated the bladder from the rectum, has received the high ſanction of Dr. Thomſon of Edinburgh. See Edinburgh Surg. Journ. N° 13.

Lateral operation.—Since the ill conſequences of the apparatus major were chiefly owing to the diſtention, contuſion, and laceration which the membranous and proſtatic portions of the urethra, and the neck of the bladder itſelf ſuffered, the idea of preventing ſuch miſchief, by cutting theſe parts to a ſufficient extent, ſeemed almoſt a certain and natural effect of any reflection beſtowed on the ſubject. The making of ſuch an inciſion conſtitutes all the particularity of the lateral operation; but as the lower ſide of the urethra cannot be divided far enough without the rectum being wounded, the cut is directed ſideways, from which circumſtance the name of the method is derived.

The lateral operation being that which, under various modifications, has now taken the place of every other method of cutting for the ſtone, it ſeems proper to give ſome account of its origin and progreſſive improvement, and of the different modes of executing it, with gorgets and a variety of lithotomes and knives.

In September, 1697, a ſort of monk, named Frère Jacques de Beaulieu, went to Paris, taking with him numerous certificates of the many cures which he had accompliſhed in ſundry places, and announcing his deſire to teach the ſurgeons of that city a new method of cutting for the ſtone. He paid his reſpects to Maréchal, then principal ſurgeon to La Charité, and requeſted leave to operate upon ſome of the patients in that hoſpital. Maréchal, however, did not think proper to truſt the living to a man, of whoſe qualifications he was entirely ignorant, and all that Frère Jacques could get granted, was permiſſion to exhibit his mode of operating upon a dead body. The reſult was, that his plan was not conſidered advantageous, and, diſſatisfied with the reception he had experienced, he quitted Paris in October, and repaired to Fontainbleau, the ſeat of the court. Here he cut for the ſtone a lad, who, in three weeks after the operation, was ſeen walking quite well about the ſtreets.

Frère Jacques put his patients under no preparatory treatment before the operation ; he placed them on the edge of a table, with a pillow under their heads, and with their legs and thighs bent and ſeparated from each other, in ſuch a way, that their heels approached their buttocks. He did not bind his patients in this poſture ; but made ſome ſtrong aſſiſtants hold them. Then, having introduced into the bladder a round, ſolid, ungrooved ſtaff, he took a long narrow knife, and made an oblique inciſion in the perineum, along the internal part of the tuberoſity and ramus of the iſchium, cutting from below upwards. In this way, he cut all the parts which preſented themſelves, without taking out the ſtaff. He now introduced his finger into the wound, in order to aſcertain the ſituation of the ſtone, and enlarged the internal opening with an inſtrument much like a ſcratching knife, but which only had one cutting edge. On this inſtrument, which he called his conductor, he paſſed the forceps into the bladder. The ſolid ſtaff was then withdrawn from the urethra, and the calculus extracted. Laſtly, ſome linen dipped in a mixture of oil and wine was applied to the wound, and the operator took final leave of his patients, telling them, that the operation was done, and that God would complete the cure.

Frère Jacques' ſucceſs at Fontainbleau changed the public opinion ſo much in his favour, that it was determined to let him operate, in the enſuing ſpring, on the patients in the Hôtel Dieu and La Charité. He was directed, however, to make ſome previous trials of his method upon the dead ſubject in the preſence of Méry, who was ordered to furniſh a report on the matter. Méry's firſt declaration was quite favourable to Frère Jacques, as it ſtated, that the neck and body of the bladder were cut inſtead of being dilated, as they were in the ordinary method at that time ; that as the ſtone was extracted at the wideſt part of the arch of the pubes, the ſymptoms were likely to be milder ; and, among other circumſtances, that the internal parts were leſs expoſed to be torn and bruiſed. Méry thought Frère Jacques' inſtruments not ſo eligible as thoſe in previous uſe, and particularly objected to the ſtaff, which, having no groove, ſerved as a very indifferent guide to the knife.

Under Méry's inſpection, Frère Jacques made further trials of the new method on dead bodies, and a ſecond report, drawn up by the former, was much leſs propitious than that which had been previouſly delivered. But neither this circumſtance, nor ſome unfortunate operations which Frère Jacques had lately performed at Verſailles and Paris, led to a rejection of the new plan ; for forty-two ſtone patients, in the Hôtel Dieu, and eighteen in La Charité, were now put under his care. Nothing could ſurpaſs the general eagerneſs to ſee him operate. There was not a phyſician, nor a ſurgeon, who was not proud of being his aſſiſtant. In ſhort, ſo vaſt was the concourſe of ſpectators, or rather, of thoſe who wiſhed to be ſuch, that guards were found neceſſary to preſerve order. Of the above ſixty patients, twenty-three died. Only thirteen were perfectly cured, and even in ſome of theſe the wound is ſaid to have afterwards broken out again. The other twenty-four remained in the hoſpitals ; ſome with an incontinence of urine ; others with fiſtulæ ; and all in a reduced ſtate, from which they are ſaid to have never recovered. On examining the bodies of the deceaſed, it appeared that, in ſome inſtances, the fundus of the bladder was wounded, while in others, the neck of this viſcus was entirely ſeparated from the urethra ; that, in women, the vagina was conſtantly pierced in two oppoſite places ; that, in both ſexes, the rectum was frequently opened ; and that, in all caſes, the parts were terribly hacked, in conſequence of no guide for the knife, and no conductor having been employed.

The ill ſucceſs of Frère Jacques' operations did not produce ſimilar ſentiments in every mind. Felix and Fagon, in France, thought that his method had merit, and that, when improved in particular points, which they ſuggeſted, it might be made far ſuperior to any other mode of cutting for the ſtone. Frère Jacques profited ſo much by their advice, that, in 1699, he operated on about ſixty perſons, moſt of whom got quite well. He ſpent the enſuing winter at Verſailles, as an inmate with Fagon, and there repeatedly practiſed lithotomy on the dead ſubject. Duverney diſſected the bodies, and though he found Frère Jacques' method far preferable to the apparatus major, which was then the only other plan in uſe, he was of opinion with Méry, " that the ſtaff would be better with a groove, as its round and ſolid form was ill ſuited for the guidance of the knife." Frère Jacques, ever ready to receive inſtruction, loſt no time in adopting the improvement. He had new ſtaffs conſtructed, and continued to employ them the reſt of his life.

In the ſpring of 1701, this celebrated lithotomiſt cut thirty-eight patients for the ſtone at Verſailles. Theſe all recovered. Fagon, who was afflicted with the diſorder, could not reſolve to put himſelf under the care of the new operator ; but was operated upon and cured by Maréchal. Frère Jacques, ſomewhat piqued at this circumſtance, quitted Verſailles, with the intention of never returning thither ; but, in 1702, he was induced to re-viſit the place at the inſtance of the Marſhal de Lorges, who was afflicted with the ſtone, and under whoſe roof were lodged twenty-two poor patients with calculi. Theſe were all operated upon with ſucceſs ; but the Marſhal, whoſe bladder contained fungous excreſcences, and ſeven ſmall ſtones, the extraction of which was tedious, died the day after ſubmitting to the operation. In conſequence of this accident, Frère Jacques determined to go into Holland. Here his ſucceſs muſt have been very conſiderable ; for he was thrice engraved ; and at Bruſſels, whither he was ſent by the magiſtrates of Amſterdam, a medal was ſtruck in honour of him, with this inſcription : *Pro ſervatis civibus.* The motto of one of the engravings is the following paſſage from Cicero : *Ægri, quia non omnes convaleſcunt, non idcirco ars nulla medicina eſt.* This alludes to the many hoſtile criticiſms which had been iſſued againſt him.

In 1712, Frère Jacques, being ſixty years of age, returned to Beſançon, his native place, where he ſoon afterwards died.

While he was at Amſterdam, his mode of operating had been obſerved by the famous Raw, who at once perceived, that the method was infinitely preferable to the apparatus major, and who, after ſome trials on the dead ſubject, put it in practice on the living. Raw's ſucceſs exceeded every thing heard of before : beſides extracting the ſtone with the utmoſt eaſe, he cured all his patients without exception. His reputation ſpread every where. Surgeons flocked from all parts to Amſterdam, in order to ſee him operate and receive his inſtructions. He cared not how many ſpectators he had ; but no one could prevail on him to divulge the particulars of his plan. To every ſolicitation on this point, his uſual reply was, " Celſum legitote," which ſeems to hint, that he was in the habit of cutting the ſame parts as were divided in the ancient operation of the apparatus minor. It is aſſerted, that he cut for the ſtone 1540 patients, and (what is almoſt incredible) they are all ſtated to have recovered, ſo that there was never any opportunity of diſſecting the bodies of any of his patients.

It was for a long while preſumed, that Raw made an opening into the bladder, without touching the neck of this viſcus, or cutting the proſtate gland. This, at leaſt, was the ſentiment of Albinus the father; but, in latter times, the general concluſion has been, that Raw muſt have divided theſe parts.

After Raw's death in 1719, experiments were made, in order to aſcertain his mode of performing lithotomy. Among others engaged in this object was Cheſelden, who, when the bladder was diſtended with an injection, ſucceeded in making an opening into this viſcus, without injuring its neck. Having tried this plan, however, on ſome of his patients, he ſoon found, that it was very liable to be followed by a fatal extravaſation of urine in the pelvis, and, conſequently, he renounced it for ever. His experiments were ſtill carried on, and at length he was convinced, that in operating with the inſtruments, and in the manner of Raw, as deſcribed by Albinus, it was impoſſible to make an opening into the bladder, without cutting the membranous part of the urethra, and the proſtate gland. Cheſelden now ſtopped his inveſtigations, and directed all his abilities to the eaſy accompliſhment of ſuch an operation. The knife, commonly employed on other occaſions, ſeemed to Cheſelden much more convenient than the pointed lithotome uſed by the Dutch ſurgeons. Inſtead of the male and female conductor in uſe with Raw, Cheſelden preferred a blunt gorget for guiding the forceps into the bladder; but he altered the handle, which, inſtead of repreſenting a ſort of croſs, was now oval, and made to incline to the left.

Having abandoned the method imputed to Raw by Albinus, Cheſelden tried a ſecond plan, which was as follows: the patient being placed in the poſture uſually choſen for lithotomy by modern operators, a grooved ſtaff was introduced into the bladder. The handle of this inſtrument was inclined towards the right groin, and firmly held by an aſſiſtant with one hand, while, with the other, the ſcrotum was ſupported. The ſkin of the perineum having been made tenſe with the operator's left thumb, a free oblique inciſion was made with a convex edged ſcalpel, much in the ſame way as is commonly done at the preſent day. The fat was next deeply cut through. The left index finger was then introduced into the upper angle of the wound, and the groove of the ſtaff being felt through the parietes of the urethra, a cut was made into this canal. The aſſiſtant that had the care of the ſtaff, was now directed to draw its concavity upward as cloſely as poſſible under the arch of the pubes, away from the rectum. All that remained to be done, was to divide the membranous part of the urethra and the neck of the bladder. This was executed by puſhing the point of the knife along the groove of the ſtaff, under the guidance of the left index finger, which, in this ſtep of the operation, was kept on the back of the ſcalpel. Having reached the proſtate gland, the inciſion was completed by the knife being moved downwards and outwards, with its edge turned towards the tuberoſity of the iſchium.

The left index finger, remaining in the wound, ſerved to guide the beak of the blunt gorget into the groove of the ſtaff. The operator now took hold of the handle of this laſt inſtrument, and, after bringing it downwards and forwards, conducted the gorget into the bladder. The ſtaff was withdrawn, the forceps introduced along the concavity of the gorget, and the ſtone extracted. Such was Cheſelden's ſecond method. It was this operation which Morand gave an account of to the French ſurgeons, after ſeeing it performed during his viſit to England at the expence of the Royal Academy of Sciences; and it is particularly worthy of notice, that foreign ſurgical writers ſeem unaware, that Cheſelden afterwards gave the preference to a third plan of operating, which has been deſcribed by Douglas in his ſecond Hiſtory of the Lateral Operation, publiſhed 1731.

We are not very well acquainted with the reaſons which led Cheſelden to abandon his ſecond method. He had, however, candidly confeſſed to Morand, that in puſhing the knife backwards along the groove of the ſtaff, he had in two inſtances wounded the rectum. Beſides, it is conjectured, that the inciſion of the proſtate gland was often too ſmall for the free tranſmiſſion of the ſtone.

Cheſelden's third, and what he conſidered as his beſt method of cutting for the ſtone, did not differ in point of principle from his ſecond plan. The ſame parts were cut, namely, the membranous part of the urethra, and the proſtate gland. The change conſiſted in a different mode of executing the inciſion, "which was now performed by moving the knife from behind forwards," inſtead of from before backwards, as in the ſecond method.

The following is the deſcription of Cheſelden's laſt and moſt improved plan, as given to us by Douglas. "In performing the lateral operation, he makes the firſt, or outward inciſion, from above downwards; beginning on the left ſide of the raphe, or ſeam, betwixt the ſcrotum and the verge of the anus, almoſt as high as where the ſkin of the perineum begins to dilate and form the bag that contains the teſticles, and from thence he continues the wound obliquely outwards, as low down as the middle of the margin of the anus, at about half an inch diſtant from it near the ſkin, and, conſequently, beyond the great protuberance of the os iſchium.

"The firſt or upper part of this inciſion is cut ſuperficial; after that, 'he plunges his knife much deeper by the ſide of the rectum, and finiſhes it by drawing his knife obliquely towards himſelf.' Theſe three motions may always be obſerved in his external inciſion; but the laſt is performed pretty much at random; his knife firſt enters the groove of the 'roſtrated or ſtraight part of the catheter, through the ſide of the bladder, immediately above the proſtate;' and afterwards, the point of it continuing to run in the ſame groove, in a direction downwards and forwards, or towards himſelf, he divides that part of the ſphincter of the bladder that lies upon the gland; and then he cuts the outſide of one-half of it obliquely, according to the direction of the whole length of the urethra that runs within it, and finiſhes his internal inciſion by dividing the muſcular portion of the urethra on the convex part of the ſtaff."

The ſecond and third of Cheſelden's methods, then, reſembled each other in the parts cut; but the firſt and third were eſſentially different, notwithſtanding the knife was in each of them plunged at once into the body of the bladder behind the proſtate gland. Cheſelden, in his firſt operation, only imitated Frère Jacques and Raw, and paſſed his knife into the bladder betwixt the veſiculæ ſeminales and tuber iſchii. He ſtopped at the back part of the proſtate gland. All his inciſion lay behind this gland. "He cut the body of the bladder only." But, in his laſt operation, he cut no part of the body of the bladder; "he introduced his knife cloſe behind the proſtate gland, and in drawing it towards him, he of courſe cut only the neck of the bladder where it is ſurrounded by that gland." John Bell's Principles, vol. ii. p. 153.

In operating after the manner aſcribed to Raw, Cheſelden loſt four patients out of ten; but in purſuing his own improved method, his ſucceſs was moſt brilliant, for, of fifty-two patients whom he ſucceſſively cut for the ſtone, all were ſaved excepting two; and it is well known, that out of two hundred and thirteen perſons, of all ages, conſtitutions, &c. on whom he operated, only twenty died. What lithotomiſt of the preſent day can boaſt of equal ſucceſs? We have ſeen lithotomy performed rather frequently with cutting gorgets of different deſcriptions, in the manner that has been of late years moſt prevalent. Out of every ſeven or eight operations, at leaſt one has had a fatal termination. We make this ſtatement with ſome degree of confidence, as we know it might be confirmed by the moſt reſpectable and impartial evidence. To what then are we to refer the few failures which Cheſelden experienced, and the vaſt number of deaths conſequent to the preſent common plan of cutting for the ſtone. The reply, in our opinion, is obvious. Cheſelden made an ample and direct inciſion into the bladder with a ſharp knife, the inſtrument, of all others, the beſt calculated for effecting a clean ſmooth diviſion of the parts, without any laceration, contuſion, or other additional injury. The moderns often make their external inciſion too ſmall, and too high up, while the internal cut, which is executed with a gorget, is almoſt always too diminutive for the eaſy paſſage of any calculi above a very moderate ſize. The difficulty of extraction muſt evidently be increaſed by the external wound being conſiderably higher up, than the internal diviſion of the proſtate gland and neck of the bladder, ſince the paſſage through which the ſtone muſt be drawn out, beſides being too ſmall, does not lead directly into the cavity of the bladder. Cheſelden, in uſing the knife, had occaſion to exert no force nor roughneſs. The moderns, whoſe gorgets are ſometimes very badly conſtructed, are often under the neceſſity of puſhing ſuch inſtruments moſt forcibly, ere the opening into the bladder can be made. The violence and injury which the parts muſt thus ſuffer, in addition to their ſimple diviſion, require from us no comment. Cheſelden, having the advantage of a free and direct opening into the bladder, never bruiſed and injured the interior of this viſcus by tedious ſearches after the ſtone with the forceps; nor when he had graſped the foreign body, did he ever bruiſe and lacerate the parts in drawing it out. His conſtant plan, on firſt introducing the forceps, was to ſearch *gently* for the ſtone *with their blades ſhut*. When he had got hold of the ſtone, he uſed to extract it "with a very ſlow motion, in order to let the parts yield as much as poſſible." On the contrary, the moderns, generally having too ſmall an opening, are often obliged to introduce and withdraw the forceps twenty or thirty times before they can accompliſh the extraction of the ſtone. Deſirous of ſhortening the buſineſs, they are guilty of manual roughneſs and violence; and not only the bladder, but the parts through which the ſtone has to paſs, are dreadfully bruiſed and injured. Some operations which we have witneſſed have been ſo long, and executed with ſuch awkwardneſs and want of gentleneſs, that we cannot help ſuſpecting, that the bladder muſt actually have been in a ſtate of inflammation before the poor patients were removed from the operating table.

Cheſelden undoubtedly was one of the moſt expert and ſucceſsful lithotomiſts that ever lived in any country, and his mode of operating, which is fully explained to us, ought, in our opinion, never to have been abandoned for the employment of cutting gorgets.

Of the beſt way of executing the lateral operation with cutting gorgets.—We ſuppoſe it muſt have been ignorance of anatomy, joined with timidity and want of judgment, that could induce ſurgeons to give up ſo excellent a plan of operating as that which was invented and practiſed by Cheſelden; for, admitting that it is ſomewhat eaſier to make the lateral inciſion with a cutting gorget, there is yet a more intereſting and weighty matter for conſideration, namely, whether the recoveries after the latter operation are, upon the whole, as numerous as thoſe which followed Cheſelden's method. This eminent ſurgeon, as we have already noticed, cut for the ſtone fifty-two patients in ſucceſſion, of whom only two died. No ſurgeon of the preſent day, in the habit of uſing a cutting gorget, can boaſt of ſucceſs at all equal to this. Our obſervation tends to the concluſion, that about one out of every ſeven or eight patients cut for the ſtone, with ſome kind of ſharp gorget, falls a victim to the operation. According to our ſentiments, a ſurgeon ſhould not regulate his conduct ſo much by the facility, as the ſucceſs of any plan; and a little more trouble and difficulty ought to be no objections, where they ſerve to give the patient a greater chance of preſervation. We know that a man cannot imitate Cheſelden, without having a requiſite knowledge of the anatomy of the parts in the perineum, and about the neck of the bladder. We can conceive at the ſame time, that a perſon might learn to operate mechanically with a gorget, and yet be totally unacquainted with the ſtructure and ſituation of the parts intereſted in the operation. It is this removal of all occaſion for ſtudy and application, that has had more effect, than any thing elſe, in keeping up the preſent ſyſtem of doing the office of the knife, with that very objectionable inſtrument a cutting gorget.

The patient is to be placed at the edge of a firm table, and the ſtaff is to be introduced into the bladder.

Then two garters, each about two yards long, are to be doubled, and put, by means of a nooſe, round the patient's wriſts. The patient is now to be deſired to take hold of the outſide of his feet with his hands, in ſuch a manner, that the fingers are applied to the ſoles, and the palms to the inſteps. The two ends of the ligature are then to be carried round the ankle, next over the back of the hand, and under the foot. Laſtly, they are to be tied. In this manner, each hand and foot may be ſecurely connected together, and the patient is fixed in the poſition the beſt ſuited for the operation.

The ſtaff, the firſt inſtrument with which the ſurgeon has any concern, is in fact nothing more than a director, adapted in ſhape to the courſe of the urethra, and furniſhed with a groove for guiding a cutting inſtrument into the bladder. (See *Surgical Plates.*) It is ſhaped very much like a ſound, or catheter. However, it is generally ſomewhat longer and more curved, and while the handle of a ſound is as ſmooth and highly poliſhed as poſſible, that of a ſtaff ought to have a rough ſurface, in order that it may be held with greater ſteadineſs and firmneſs. Two advantages ariſe from having the ſtaff ſufficiently curved; *viz.* its convexity is more plainly diſtinguiſhable in the perineum; and on depreſſing the handle of the inſtrument, that part of the groove which is at the neck and within the cavity of the bladder, may be more readily made to aſſume a direction correſponding to the axis of this viſcus. The utility of the length of the inſtrument is very obvious, as the operator is thereby leſs liable to ſuppoſe the extremity of the ſtaff to be within the bladder, when it is not ſo; and it is plain, that the groove ſhould always extend beyond the beak of the gorget, even when the latter inſtrument has been puſhed as far as the operator judges requiſite.

An aſſiſtant is to hold the ſtaff, making its convexity prominent in the perineum, by preſſing the whole inſtrument downwards, and inclining its handle towards the patient's abdomen. The perſon who has charge of the ſtaff, ſhould alſo turn the groove a little towards the left ſide of the perineum,

neum, and raiſe the ſcrotum with his left hand, in order to expoſe the perineum completely to the ſurgeon's view.

The next conſideration is the manner of making the external inciſion. A moſt common error is that of beginning the cut too high up. Nearly all the old ſurgeons commit this fault, by commencing the inciſion over the bulb of the urethra. This practice is above all things diſadvantageous, eſpecially when the operator makes the outward wound rather too ſmall. Suppoſe, for inſtance, that the ſurgeon begins the inciſion as high as the bulb of the urethra, and does not carry it ſufficiently far downwards; and that he next divides the proſtate gland and neck of the bladder with the gorget. Now, on attempting to take out the ſtone, the external part of the wound is too high, in regard to the internal portion; and the paſſage, through which the ſtone is to be extracted, not being ſtraight and direct, as much impediment to the extraction is thereby occaſioned as from the circumſtance of the wound being too ſmall. We are decidedly of opinion, that "a free and direct opening for the paſſage of the ſtone ought always to be made in the operation of lithotomy;" and that the fatal termination of numerous caſes is entirely owing to the wound not being ſufficiently ample and direct. The laceration of the parts, which muſt happen under ſuch circumſtances, is too frequently productive of peritoneal inflammation, the moſt alarming conſequence of the operation. Nothing has a greater tendency to render the wound indirect, than making the inciſion through the ſkin too high up; or, in other words, ſo high as to intereſt the bulb of the urethra.

On the contrary, the wound ſhould commence over the membranous part of the urethra, at the place where the operator means to make his firſt cut into the groove of the ſtaff; and the inciſion is to extend about three inches obliquely downwards, to the left of the raphe of the perineum. The point to which it ought to be directed, is the centre of a line drawn from the anus to the tuberoſity of the iſchium.

The requiſite diviſion of the integuments being made, the next object is to divide the tranſverſales perinæi muſcles, and to make an opening into the membranous part of the urethra, ſo as to be able to feel diſtinctly with the finger the groove and edges of the ſtaff.

The operator has now to accompliſh a very important object, and one that is for the moſt part ſadly neglected: we allude to cutting the left ſide of the urethra with the knife, as far as poſſible along the groove of the ſtaff towards the bladder. In doing this, the point of the ſcalpel ſhould be placed in the groove of the ſtaff, and the edge be turned to the left, while the operator's left fore-finger, applied to the back of the blade, ſerves to guide its courſe with greater ſteadineſs and ſecurity. When this part of the operation is carefully done, very little remains to be effected by the gorget.

Were the ſurgeon, with too much boldneſs, to lay open the lower part of the urethra onward to the bladder, he would inevitably wound the rectum; "becauſe," as an excellent writer has obſerved, "the inciſion being carried on from the urethra, it will neceſſarily lead to that part of the neck of the bladder that lies upon, and is contiguous to, the rectum." (Sharp in Critical Inquiry, &c. p. 212. edit. 4.) But when the urethra is divided in the manner above recommended, with the edge of the ſcalpel turned ſideways, no riſk of cutting the inteſtine is encountered.

The next important ſtep is to divide the proſtate gland and neck of the bladder; for which purpoſe, the gorget, that diſgraceful inſtrument, which we ſhould like to ſee expelled from ſurgery, is deſigned.

Mr. Serjeant Hawkins has made his name exceedingly famous, by his having been the inventor of cutting gorgets. We have already related how the ancient ſurgeons ſometimes employed blunt gorgets for dilating the parts, in the performance of the apparatus major. A reference to the ſurgical plates of this work will more readily convey an idea of what a gorget is, than any verbal deſcription. There we have given repreſentations of the blunt gorget, as well as of ſharp gorgets, deviſed by Hawkins, Cline, and Abernethy. The gorget of Mr. Cline appears to us the moſt eligible, as it will make the freeſt opening into the bladder, and cut in the moſt deſirable direction. Its edge, being quite ſtraight, may be readily ground very ſharp, and is beſt ſuited for making an even clean inciſion. By cutting laterally, inſtead of more or leſs obliquely upwards, a larger inciſion may be ſafely made with it than with moſt other gorgets, which, having their edges turned upwards, cut in a direction where the rami of the oſſa iſchium converge, and leave inſufficient room for the eaſy paſſage of a large ſtone; and where alſo the trunk of the pudendal artery is liable to be injured, in making a wound even of moderate extent. We are firmly perſuaded of the truth of Ponteau's opinion, that the ſtone ought always to be extracted where the arch of the pubes is wideſt. Cline's gorget, beſides having the material advantages of making the freeſt opening, and cutting in the moſt deſirable direction, alſo poſſeſſes the excellence of being diveſted of that very uſeleſs and objectionable part, the blunt prominence on the left hand of the beak, ſometimes termed the ſhoulder of the gorget. This ſhould always be filed away, as it can only ſerve to render the introduction of the inſtrument more difficult.

We ſhould like Mr. Abernethy's gorget very well, if its edge were ſomewhat more extenſive, and had a more horizontal direction. But the firſt improvement would be improper without the laſt; ſince a freer cut ſo much upwards muſt endanger the pudendal artery.

Every ſurgeon, before undertaking lithotomy, ſhould be careful that the beak of the gorget and the groove of the ſtaff fit each other with preciſion. The embarraſſment and riſk of doing miſchief, into which the operator would fall, could he not make the beak ſlide along the groove, muſt be plain to every underſtanding.

Having divided the urethra a conſiderable way towards the neck of the bladder, in the manner explained above, the operator is to place the beak of the gorget in the groove of the ſtaff; and, being ſure that this is accompliſhed, he is to riſe from his chair, and take hold of the handle of the ſtaff with his left hand, while with his right he holds the gorget with its beak carefully maintained in the groove of the ſtaff, along which it is to glide into the bladder. But, before puſhing the gorget onward, a moſt important thing is to be obſerved: this is "to bring forward the handle of the ſtaff, ſo as to elevate the extremity of the inſtrument in the bladder; by which means, the gorget can be introduced along the groove of the ſtaff, in the direction of the axis of the above viſcus. In fact, the gorget ſhould always be introduced nearly in a direction correſponding to a line drawn from the os coccygis to the umbilicus." By following this plan, the gorget can hardly ever wound the rectum, or inſinuate itſelf into the cellular ſubſtance between this inteſtine and the bladder. It is evident, however, that there can be no ſafety, if the beak of the gorget ſhould happen to ſlip out of the groove, which is deſigned to guide it.

Immediately the gorget has been introduced, the ſtaff is to be withdrawn, and a ſuitable pair of forceps is to be paſſed, along the upper ſurface of the gorget, into the bladder, for the purpoſe of ſeizing and extracting the ſtone.

While the operator is paſſing the forceps along the gorget, the latter inſtrument muſt be kept quite motionleſs, leſt its ſharp edge ſhould do miſchief; and as ſoon as the forceps is in the bladder, the cutting gorget is alſo to be taken away.

Delineations of the forceps, uſed in lithotomy, will be found in the ſurgical plates of this work. We ſhall only obſerve, reſpecting this inſtrument, that the operator ſhould be provided with at leaſt three or four pairs of different ſizes; and that they are commonly made of too thick and clumſy a conſtruction, whereby they of themſelves almoſt occupy the whole of the paſſage through which the ſtone is to be drawn.

Our deſcription has now advanced to that point of the operation, when the ſtaff and gorget have been withdrawn, leaving the forceps introduced. The next object is to get hold of the ſtone with the forceps. In doing this, the ſurgeon will do well to remember the judicious mode purſued by Cheſelden, as detailed in our account of this gentleman's improvements. He ſhould not unmeaningly expand the inſtrument, as ſoon as it is in the bladder; neither ſhould he awkwardly thruſt it about at random, without any determinate ſcheme. The moſt adviſable method at firſt is not to open the forceps, but uſe the inſtrument as a kind of probe, for aſcertaining the exact ſituation of the ſtone. If this body ſhould be lodged at the lower part of the bladder, juſt behind the neck of this viſcus, as is moſtly the caſe, and be diſtinctly felt below the blades of the forceps, the operator is to open the inſtrument immediately over the ſtone, and, after depreſſing the blades a little, is to ſhut them, ſo as to graſp it. Great care, however, muſt be taken not to ſhut the inſtrument in any other than a gentle manner, as breaking the ſtone is an exceedingly unpleaſant and troubleſome occurrence. Cheſelden, we are informed, uſed, when the ſtone was found ſoft, to interpoſe his finger between the blades of the forceps, in order to keep them from making too much preſſure. Certainly it is far more ſcientific to uſe the forceps at firſt, merely to aſcertain the poſition of the ſtone; for, when this is known, the operator can much more eaſily graſp the extraneous body in a ſkilful manner, than if he were to open the blades of the inſtrument immediately, without knowing where they ought next to be placed, or when ſhut. No man can doubt, that the injury which the bladder frequently ſuffers, from reiterated and awkward movements of the forceps, has a conſiderable ſhare in giving riſe to ſuch inflammation of the viſcus, as often ſpreads to the peritoneum and bowels, and occaſions death.

When the ſtone is found to be ſo large, that it cannot be extracted without violence and laceration, the ſurgeon may either break the ſtone with a ſtrong pair of forceps, conſtructed with teeth for that purpoſe; or by means of Mr. H. Earle's inſtrument; or elſe he may enlarge the wound with a common ſcalpel, or a probe-pointed biſtoury, introduced under the guidance of the fore-finger of the left hand.

To the employment of the knife, in this circumſtance, we have to expreſs our decided preference. Breaking the ſtone in the bladder ſhould always be avoided, if poſſible; as it creates ſuch a chance of calculous fragments being left behind, and obliges the ſurgeon to diſturb and hurt the bladder too much by the repeated introductions of the forceps. We wiſh it, however, to be well underſtood, that when the ſtone is exceſſively large, and cannot be brought through as free an opening as can be prudently made, without the employment of unwarrantable force, it is the duty of the operator to try to break it.

When this has been done, and as many of the broken pieces have been taken out as can be diſcovered with the forceps, the ſurgeon ſhould introduce his finger, in order to feel whether any fragments ſtill remain behind. If they ſhould do ſo, his beſt plan, provided they are very ſmall, is to inject lukewarm water, with moderate force, through the wound into the bladder, for the purpoſe of waſhing them out. A ſort of ſcoop, uſually contained in every caſe of inſtruments for lithotomy, may ſometimes be uſeful in extracting pieces of broken calculi. See the ſurgical plates.

The operator ought always to examine a ſtone as ſoon as it is extracted; if its whole ſurface be rough, it is a preſumptive ſign that there is no other calculus preſent; if its outſide ſhould be ſmooth on one ſide and rough on the other, it is not improbable that there are other ſtones. But in every inſtance, the ſurgeon ſhould introduce his fore-finger, in order to obtain deciſive information on this point; for it would be unpardonable to put the patient to bed while another ſtone remains in his bladder.

Sometimes ſtones cannot be graſped with the forceps, unleſs raiſed by the index and middle finger of the left hand, introduced into the rectum. Firſt Lines of the Practice of Surgery, p. 532—537. edit. ii.

Of the objections to cutting gorgets.—Mr. John Bell of Edinburgh, in his Principles of Surgery, vol. ii. has freely delivered his ſentiments on the dangers and diſadvantages of the cutting gorget, and as we think there is much reaſon and truth in what he has ſaid, his obſervations appear to us well worthy of the moſt ſerious conſideration. They tend to ſhew that there is no method of performing lithotomy ſo excellent as that with only a ſtaff and a ſcalpel, and that if ſurgeons would take the trouble to qualify themſelves for this laſt mode of operating, a thing by no means difficult, all cutting gorgets might be for ever laid aſide, to the great benefit of mankind, and the real improvement of ſurgery. Mr. John Bell reminds us that "*the gorget ſlips!* and all the ſurgeons of Europe confeſs it! it ſlips in the hands of the moſt ſkilful ſurgeons, and no one can be reſponſible for the conſequences of a thruſt ſo deſperate, and requiring ſo much force. It ſlips ſo frequently, and is avowedly ſo little under the controul of the operator, that no man ventures to blame his brother for a misfortune which may happen in his own hand. So imperfect is the inſtrument, and ſo dangerous this plunge, that to prevent the gorget being driven through the fundus of the bladder, is a point of ſo much importance as to occupy, to this day, the genius of inventors, who have thought to guard the edge by a double, or ſlipping gorget! and ſo far is the inciſion, after it is ſafely made, from being adequate to the extraction of the ſtone, that the ſize and form of the gorget, and eſpecially the expanſion of its blade, and the broadneſs of its cutting edge, varies every day. The inſtrument was once conical, but is now cylindrical; it was once narrow, but is now broad; it was once double, with the beak in the centre; it is now ſingle, with the beak on one ſide; when firſt ſharpened by ſir Cæſar Hawkins, it was round, becauſe it had been immediately before a mere dilator; it is now flat, and entirely reſembles a knife.

"It is not without reluctance, (proceeds Mr. John Bell,) that I rank this among the inventions, where mechaniſm is ſubſtituted for ſkill. If this form of inſtrument were found ſafe in practice, I ſhould be as little apt as any man to be infected by ſpeculative fears; but it is a murderous weapon! When the daſh is made with the gorget, either it is at once ſucceſsful, or, if wrong, is irretrievably ſo; for though in operating with the knife, you can make a ſecond inciſion, in operating with the gorget, if you fail in the firſt, you can make no ſecond plunge. The beſt operators in this country, among whom I have no doubt I may reckon Mr.

Earle, acknowledge the dangers of this operation in the fulleſt and moſt unqualified terms: ‘I have more than once known a gorget, though paſſed in the right direction, puſhed on ſo far, and with ſuch violence, as to go through the oppoſite ſide of the bladder.’ (Earle on the Stone, p. 33.) I have myſelf, (ſays Mr. John Bell,) ſeen it driven, God knows where, deep out of ſight, up to the hilt, without one drop of urine iſſuing, without the operator ever reaching the ſtone. Obſerve but the force with which the operator drives in the gorget; mark the ſtruggle with which he diſengages the beak of the gorget from the groove of the ſtaff; hearken to the audible clack with which the beak of the gorget ſhoots off from the groove of the ſtaff; and if this moment of violence do not conſpire with the outcries of the unhappy patient to perſuade you of the dangers of this operation, you can have but little pretenſion to either feeling or knowledge. Such is the rude violence with which the gorget is driven inwards, that Bromfield, even when operating with a blunt gorget, a mere dilator burſt through the bladder and peritoneum; his gorget went almoſt beyond his reach into the abdomen, while the bowels of the boy fell down into his hands.

“But, (ſays Mr. J. Bell,) there is one paramount objection, independent of the many dangers which attend this puſh of the gorget; ‘the inſtrument, guide it how you will, makes an inciſion inadequate to the eaſy extraction of the ſtone!’ I have often compared the inciſions I have made with the knife and with the gorget, upon the dead body. I have obſerved alſo, in the time of operating, how difficultly the opening of the proſtate admits even the forceps, how impoſſible that ſuch an imperfect inciſion ſhould eaſily allow the extraction of the ſtone. In all caſes of particular difficulty, where, uſing the privilege of an aſſiſtant, I have introduced my finger, I have felt diſtinctly the ſtricture of the gland, the greater part of it being left entire. The inciſion in the gland often admits the forceps ſo difficultly, that I am well aſſured the gland itſelf has ſometimes, by the mere puſhing of the forceps againſt this firm and narrow opening, been entirely ſeparated from the urethra! and after the forceps are puſhed ſucceſsfully through this narrow opening, and the ſtone caught betwixt their blades, all that remains of the gland is inevitably lacerated with much danger and pain. But I would more willingly quote any authority than that of my own diſſections, or experience. Camper, who has ſtudied this ſubject, ſays “incredibile eſt, quàm parva plaga ab omnibus etiam dexterrimis infligatur; nunquam forcipem robuſtam exciperet niſi dilataretur. Hawkenſius ſolo conductore, cujus margo dexter in aciem aſſurgit, idem præſtat; *omnes plagam dilatant, ut calculum extrahant; dilaceretur igitur ſemper veſicæ oſtium et proſtata.*” P. 14.

“But, (continues Mr. J. Bell,) higher and better authority remains behind. Deaſe was, if I judged rightly of his talents, a ſtern and rude ſurgeon, but perfect in all the theory and practice of his art; he was not very explicit in his communications with me, but from the manner and the movement of his hand, in demonſtrating to me, rather than from what he ſaid, I conclude that he cut after the manner of Raw, making the inciſion with the right hand, while he held the ſtaff with his left. “In all the trials, (ſays Deaſe,) that I have made with the gorget on the dead ſubject, I have never found the opening into the bladder ſufficiently large for the extraction of a ſtone of a middling ſize, without a conſiderable laceration of the parts. I have frequently taken the largeſt ſized gorget, and could not find, that in the adult ſubject, I ever entirely divided the proſtate gland, if it was any way large; and in the operations that were performed here on the living ſubject, the extraction was painfully tedious, and effected with great difficulty, and in ſome caſes not at all.” See John Bell's Principles of Surgery, vol. ii. p. 173—176.

We coincide entirely with Mr. J. Bell reſpecting the dangers and diſadvantages of the cutting gorget, and could adduce ſeveral caſes where operators have committed, with this inſtrument, the moſt fatal blunders. It is alſo our conviction that many deaths, after the operation, are owing to the conſequences of the opening being, in general, too ſmall, ſo that the forceps are ſometimes introduced and withdrawn twenty times before the ſtone can be extracted, and when this is accompliſhed, it is with immenſe violence and laceration. The moſt perfect lithotomy appears to us only to admit of being done with a ſcalpel and a ſtaff; and the more we reflect on the ſubject, the more we are convinced of the excellency of Cheſelden's practice

Of ſome particular methods and inſtruments.—The ſubject of lithotomy is almoſt an endleſs one, and many ſheets of this work would be taken up by a full explanation of all the various methods. Such readers as wiſh for ſo minute and long an account, are particularly referred to Sabatier's Médecine Opératoire, tom. ii. and to Mr. John Bell's Principles of Surgery, vol. ii. May it be ſufficient in this publication to make mention of ſome of the moſt intereſting of theſe numerous propoſals, in doing which, we ſhall avail ourſelves of ſome remarks contained in an inſtructive paper inſerted in the Edinb. Med. and Surg. Journal, vol. iv. by Mr. Allan Burns, lecturer on anatomy and ſurgery, Glaſgow.

Frère Côme's method with the lithotome caché.—John de Saint Côme, of the order of Feuillans at Paris, was the inventor of a knife, concealed in a ſheath, out of which the blade ſprings, on touching a kind of lever at the ſide of the handle of the inſtrument. The diſtance to which the blade ſtarts out, may be regulated by the ſurgeon before the operation, according to the extent of the wound that he may be deſirous of making. The patient being placed as in the lateral operation with the gorget, and a ſtaff introduced, the ſurgeon, with a ſcalpel, is to begin the firſt inciſion on the left ſide of the raphe of the perineum, about ten lines in front of the anus. This cut is to be continued obliquely downwards and outwards, as far as the centre of a line extending from the anus to the inſide of the tuberoſity of the iſchium. The external inciſion is to divide the integuments of the left ſide of the perineum, the accelerator urinæ, the erector penis, the tranſverſus, and the front fibres of the levator ani. Theſe parts having been cut, the index finger of the left hand is to be introduced into the left angle of the wound, with its radial ſide downwards. The right edge of the groove of the ſtaff is to be placed between the nail and ſkin at the end of the finger. The point of the ſcalpel is to be conducted into the groove of the ſtaff along the nail, which faces the left. The index finger is now to be turned, in order that its extremity may preſs upon the point of the knife, which all along is to be held with the right hand, like a writing pen. The urethra is thus to be ſlit open to the extent of five or ſix lines. The nail of the left index finger is next to be placed in the groove of the ſtaff, and is to ſerve as a means of guiding the end of the lithotome into that groove. As ſoon as the latter object has been accompliſhed, the finger is to be withdrawn; the ſurgeon, with his left hand, is to take hold of the handle of the ſtaff; and by one ſimultaneous movement, he is to raiſe the two ends of the inſtruments together towards the ſymphiſis of the pubes, by which means the lithotome will be eaſily conducted into the bladder. The entrance of the lithotome into the cavity of this viſcus will be indicated by ceſſation of reſiſtance, and the freer iſſue of the urine. The end of this inſtrument, being in contact with the cul-de-ſac extremity of the groove of the ſtaff, muſt be diſengaged by a ſlight lateral movement. The ſtaff is now to be withdrawn. The operator, with his left thumb and index finger, is then to take hold of the lithotome, about the place where its ſheath and handle meet. He is to conduct the inſtrument under the ſymphiſis pubis, turning the edge downwards and towards the left ſide of the perineum, in the direction of the external inciſion. On preſſing a lever, the blade of the lithotome quits the ſheath, when the inſtrument is to be drawn out horizontally. Thus the proſtate and neck of the bladder are divided. The forceps are then introduced, and the operation finiſhed in the ordinary way.

The lithotome caché of Frère Côme is yet employed at the Weſtminſter hoſpital, and has been lately tried by Mr. A. Cooper. It is ſtill more commonly uſed in France. The objections, however, which have thrown diſcredit upon it, are, that from its mechaniſm, and the ſtructure of the parts about the pelvis, it is likely to wound the pudendal artery; that the bladder, if collapſed, may be injured in more than one place; and that if the knife be directed downwards too obliquely, the rectum is apt to be cut.

Apparatus altus as modified by Frère Côme and Deſchamps.—Abſolute neceſſity led to the introduction of the high operation by Franco in 1561; and the ſame cauſe occaſioned its revival, in 1658, by Frère Côme. The operation, as performed by Franco, was defective: a high inciſion was alone made into the bladder; this viſcus was opened above the pubes, below the point where the peritoneum is reflected over the abdominal muſcles: the ſtone was eaſily extracted; but as there was no dependent opening from the bladder, the urine was apt to inſinuate itſelf into the cellular membrane about the pubes, to irritate and inflame the parts, and to produce either gangrene or ſuppuration, and the formation of ſinuſes. Theſe diſadvantages led to the diſuſe of the apparatus altus, till revived and new-modelled by Frère Côme, who propoſed to open the bladder in perineo, and then, through an opening made juſt above the pubes, he introduced a ſcalpel with a button point, with which he ſlit up, for an inch or two, the linea alba; the knob on the end of the knife puſhing aſide the peritoneum. After this, he introduced, by the aperture in perineo, a ſtaff, with which he made the bladder project through the opening between the recti muſcles. This done, he cut into the front of the bladder, and either with his finger and thumb, or with a pair of forceps, he took out the ſtone. In this way he extracted from the bladder a calculus, that weighed twenty-four ounces. On this method Mr. Allan Burns remarks, that it might with propriety be adopted, were it not for the danger attendant on the double inciſion into the bladder, and the protraction of the operation by the diſſection about the perineum. Indeed, as modified by Deſchamps, who, in place of the puncture in perineo, perforates the bladder from the rectum, it has met with the approbation of Mr. Thomſon of Edinburgh, who conſiders this, on particular occaſions, to be the moſt adviſable method of operating. Mr. A. Burns thinks, however, that if the bladder be thickened and indurated, it will be impoſſible to raiſe it with the cannula above the pubes. Hence, this plan is only admiſſible, when we have reaſon to ſuppoſe that the ſtone is too large to be removed by the perineum, and that the bladder is healthy. Here the puncture from the rectum is ſimple, attended with no increaſe of the danger, allows the bladder to be elevated with the cannula, and ſecures a dependent outlet for the urine. Thus we avoid the neceſſity of any diſcharge by the wound above the pubes; we run no riſk of the urine inſinuating itſelf into the cellular membrane, no inflammation is excited, no ſinuſes are formed; conſequently, the perſon ought ſpeedily to recover. Edin. Med. and Surg. Journ. vol. iv.

Invention of ſtaffs, from which the gorget cannot ſlip.—The danger of the gorget ſlipping out of the groove of the ſtaff has been already ſufficiently commented on. Le Cat, in 1747, and ſir C. Blicke, more lately, endeavoured to obviate ſuch riſk, by propoſing to uſe ſtaffs with contracted grooves. The beak of the gorget is locked and fixed in the groove of the ſtaff, till it has arrived near the end of this latter inſtrument, where the groove has a wider conſtruction. Notwithſtanding the plauſibility of this contrivance, there are reaſons which have deterred practitioners from employing it. Few ſurgeons have been inclined to truſt to the ſort of gorget that muſt be uſed; the point of contact of the beak and body of the inſtrument being neceſſarily ſo ſmall, that on the ſlighteſt deviation from the direct line, in puſhing ſuch a gorget into the bladder, the beak breaks off, the gorget ſeparates from the ſtaff, and the ſeminal veſſels and rectum are expoſed to injury. Beſides, another objection is, that the gorget is frequently ſtopped in the groove of this kind of ſtaff, at the moſt critical period of the operation.

Methods of Le Dran, Deaſe, and Muir.—Le Dran, in 1741, publiſhed his Operations of Surgery. In this work, the author deſcribes an operation, the introduction of which has been claimed by ſeveral ſince his time. The principle of the plan alluded to was to reduce the male into the ſtate of the female urethra.

The late Mr. Deaſe of Dublin, and Mr. Muir of Glaſgow, reflecting that the great cauſe of the gorget ſlipping from the ſtaff depends upon the former being puſhed along a curved ſurface; and obſerving, that ſuch an accident ſeldom or never happens on females; have propoſed, like Le Dran, to make the male urethra reſemble the female. To accompliſh this, they introduce, as uſual, a curved grooved ſtaff into the urethra, and make the common inciſion in perineo: they then open the membranous part of the urethra; but, inſtead of now introducing the gorget, they conduct along the groove a female ſtaff, and immediately withdraw the curved one. With the left hand they take hold of the handle of the ſtraight ſtaff, and with the right introduce the gorget.

Double ſtaffs.—It is ſaid that ſome operators have experienced conſiderable difficulty in finding the groove of the ſtaff in the perineum. To facilitate this buſineſs is the principal deſign of the double ſtaff, an inſtrument which is now quite laid aſide. In fact, the trouble of cutting into the ſtaff is not great enough, to render any invention of this ſort at all important.

The firſt inſtrument for this purpoſe we find deſcribed by Deſchamps, as the invention of Jarda, a ſurgeon at Montpellier. According to Mr. A. Burns, it reſembles Earle's double ſtaff; but is more complex. It conſiſts of a curved ſtaff, intended to be introduced along the urethra into the bladder, and having connected to its handle, by means of a hinge, another ſtaff, ſhorter than the former, and ſharp at its end. When Jarda had applied the ſhort ſtaff to the perineum, he puſhed its point through the ſkin, behind the bulb of the urethra, into the groove of the long ſtaff already paſſed through this canal. This ſupplementary ſtaff, in both Jarda and Earle's inſtrument, is intended to conduct the knife into the groove of the ſtaff. But Jarda aimed at more: he wiſhed to ſecure the rectum from injury, by introducing into the anus a limb of the inſtrument, which he expected would puſh the gut aſide. By machinery, he alſo contrived to ſupport the ſcrotum. Edinb. Med. and Surg. Journal, vol. iv.

Mr. Allan Burns' method. — The plan introduced by Cheſelden, and revived by Mr. John Bell, is that which Mr. A. Burns would aſſume as the baſis of the operation; but with it he propoſes to blend Mr. Deaſe's mode.

" For more than twelve months," ſays Mr. Burns, " I have been in the habit of ſhewing ſuch an operation, which is as ſimple in its performance as the one in general uſe, is attended with leſs danger to the patient, permits of an inciſion varying in ſize according to the wiſh of the operator, and completely prevents injury of the rectum or pudic artery. To perform this operation, I introduce into the urethra a common curved ſtaff, then make the uſual inciſion into the perineum, divide fully and freely the levator ani, ſo as to expoſe the whole extent of the membranous part of the urethra, the complete extent of the proſtate gland, and a portion of the ſide of the neck of the bladder. When this part of the operation is finiſhed, I open the membranous part of the urethra, and introduce, through the ſlit, a ſtraight or female ſtaff, with which I feel the ſtone, and then withdraw the curved ſtaff. Next I feel beyond the proſtate for the inſtrument, and then perforate the coats of the bladder with a curved knife, the point of which is to be inſerted in the groove of the ſtaff. This done, I graſp the handle of the ſtaff firmly in my left hand, and with the right lay hold of the handle of the knife. Having aſcertained that the two inſtruments are in fair contact, I reſt the one hand upon the other, preſſing them together, and then, by a ſteady extraction, I pull out the knife and ſtaff together, which is preferable to drawing the knife along the ſtaff: it prevents the riſk of the one ſlipping from the other; it guards the bulb of the urethra, and every other part from injury; for, between them and the cutting inſtrument the ſtaff is interpoſed. In the introduction of the knife, however, ſome caution is neceſſary, and a clear knowledge of the relative ſituation of the parts in the pelvis is requiſite; but this information is equally neceſſary in operating with the gorget. When introducing the knife, the ſide of the blade muſt be laid flat along the fore-finger of the right hand, which is to project a little beyond the point. In this ſtate, the finger and knife are to be entered into the wound, oppoſite the tuber iſchii; but, in proportion as they paſs along, they are to be inclined forward, till at laſt, with the point of the finger, the ſtaff be felt through the coats of the bladder, a little beyond the proſtate, and rather higher than the orifice of the urethra. Here the knife is, with the finger, to be puſhed through the bladder; and when the point is fairly fixed in the groove of the ſtaff, the operation is to be finiſhed by the ſteady extraction of both inſtruments. In operating with the gorget, it is neceſſary that the bladder be more or leſs diſtended; a circumſtance, in ſome caſes, with difficulty accompliſhed, from the irritability of this viſcus. In operating with the knife, the parts can be as ſafely cut when the bladder is empty as when full; indeed, perhaps, with greater ſafety: for, when not dilated, the ſhoulder of this viſcus can more eaſily be puſhed in, ſo as to permit the finger to reach the ſtaff. Some have imagined, that the introduction of the point of the knife into the cavity of the bladder muſt be dangerous, inaſmuch as we are liable to wound the ſides, in ſearching for the groove of the ſtaff. This objection is the reſult of an inaccurate knowledge of the ſtate of the parts: for, in fact, we never grope in the bladder with the point of the knife; but, with the finger, puſh in the ſide of this viſcus into cloſe contact with the ſtaff, into the groove of which the knife enters, as ſoon as it has paſſed through the coats of the bladder. Others again have objected to this mode of operating, on the idea of its being more tedious in performance than with the gorget. This is alſo founded on a miſtaken notion. True it is, indeed, that were a ſurgeon, who has been much in the habit of operating with the gorget, to exchange it for the knife, he would undoubtedly be longer of performing the operation in the latter way: but the ſame does not hold good reſpecting thoſe who have never before operated in either mode. From all that I have ſeen, I would ſay, that the one operation may be as expeditiouſly performed as the other: but even admitting that the operation with the knife uniformly required a little longer time, ſtill I think that, if ſafer, it ought to have the preference." Edinb. Med. and Surg. Journal, vol. iv. p. 65—67.

The inſtruments, uſed by Mr. Burns, are repreſented in the ſurgical plates of this Cyclopædia.

We ſhall merely ſay, that we think that the above plan of operating is much better then the common mode of cutting for the ſtone with a gorget; nor can it be found fault with on the ground of difficulty. Notwithſtanding its merit, however, few ſeem diſpoſed to give it a fair trial; but continue the employment of that dangerous and inſufficient inſtrument, the gorget, as much as ever.

Of lithotomy, as performed with common ſcalpels, and ſome other kinds of knives.—The fact of Cheſelden having cut for the ſtone fifty-two patients in ſucceſſion, of whom all recovered, excepting two, is an invincible argument in favour of his method of operating. It may be expected, that we ſhould deſcribe the mode of executing the operation with a ſcalpel; but after the full account which we have delivered of Cheſelden's plan, this duty in reality becomes ſuperfluous. The few judicious ſurgeons of the preſent day, who have given the preference to the common ſcalpel, have all operated either after Cheſelden's ſecond or third manner. The laſt has been choſen by Mr. John Bell, and is that which was crowned with ſuch matchleſs ſucceſs in the practice of its inventor. The lateral operation, as thus executed by Cheſelden, was truly once the pride of Engliſh ſurgery, to uſe an expreſſion of that able profeſſor, Dr. J. Thomſon of Edinburgh. Other operators have preferred operating after the manner of Cheſelden's ſecond method, *viz.* by cutting from the urethra towards the bladder.

Mr. Charles Bell has propoſed the employment of a ſtaff, the groove of which, towards the extremity of the inſtrument, runs along its right ſide or edge. Operative Surgery, vol. i.

It would be a tedious and endleſs buſineſs to deſcribe all the various knives which different ſurgeons have ſuggeſted for lithotomy. The late Mr. Hunter had a particular one. Mr. Aſtley Cooper has uſed a knife, much reſembling a common diſſecting ſcalpel, but having a beak, by which it may be guided along the groove of the ſtaff. We hear that this diſtinguiſhed ſurgeon is now trying Frère Côme's lithotome caché. A much approved knife for lithotomy was ſome time ſince invented by Mr. Gibſon, and another by Mr. T. Blizard. Engravings of all theſe will be found in the ſurgical plates of this work. Our objection to theſe beaked knives is, that they are in reality gorgets.

Of lithotomy on Women.—Women ſuffer much leſs from the ſtone than men, and far leſs frequently ſtand in need of this operation. It is not, however, that their urine will not ſo eaſily produce the concretions, which are termed urinary calculi. The reaſon is altogether owing to the ſhortneſs, largeneſs, and very dilatable nature of the female urethra; circumſtances, which in general render the expulſion of the ſtone with the urine almoſt a matter of certainty. The records of ſurgery preſent us with numerous inſtances, where calculi of vaſt ſize have been ſpontaneouſly voided through the meatus urinarius, either ſuddenly without pain, or after more or leſs time and ſuffering. Heiſter mentions ſeveral well authenticated examples of this kind. Middleton has alſo related a caſe, where a ſtone, weighing four ounces, was expelled in a fit of coughing, after lodging in the paſſage a week. Collot ſpeaks of another inſtance, where a ſtone, about as large as a gooſe's egg, after lying in the meatus urinarius ſeven or eight days, and cauſing a retention of urine, was voided in a paroxyſm of pain. A remarkable caſe is related by Dr. Molineux in the early part of the Philoſophical Tranſactions: a woman voided a ſtone, "the circumference of which meaſured, the longeſt way, $7\frac{6}{15}$ inches, and round about, where it was thickeſt, $5\frac{3}{4}$ inches, its weight near $2\frac{1}{2}$ ounces troy."

Sometimes, after the paſſage of large calculi, the patient has been afflicted with an incontinence of urine; but this grievance, in general, laſts only a ſhort time.

The naturally large ſize, and dilatable nature of the female urethra, have ſuggeſted the plan of endeavouring to expand this paſſage by various means, ſo that a ſtone in the bladder may be taken out with a pair of forceps, without uſing any cutting inſtrument at all. This method was propoſed by Douglas nearly a century ago, who not only recommended ſponge for the purpoſe, but alſo dried gentian root, as being more gradual in its expanſion, and better adapted to the object.

Mr. Bromfield has given the caſe of a young girl, where he effected the dilatation by introducing into the meatus urinarius the appendicula cæci of a ſmall animal in a collapſed ſtate, and then filling it with warm water, by means of a ſyringe. The piece of gut, thus diſtended, was drawn out, in proportion as the cervix veſicæ opened, and in a few hours the dilatation was ſo far accompliſhed, that the calculus had room to paſs out. See Chirurgical Obſ. and Caſes, vol. ii. p. 276.

Mr. Thomas lately met with a caſe, where, after dilating the meatus urinarius with ſponge tent, he ſucceeded in extracting an ear-picker, which lay acroſs the neck of the bladder. The paſſage was ſo much enlarged, that the left fore-finger was moſt eaſily introduced, and, (ſays this gentleman,) "I believe, had the caſe required it, both thumb and finger would have paſſed into the bladder without the ſmalleſt difficulty."

After adverting to this caſe, and other facts proving the eaſe with which the female urethra can be dilated, Mr. Thomas remarks; "If theſe relations can be credited, and there is no reaſon why they ſhould not, I can hardly conceive any caſe, in a young and healthy female ſubject, and where the bladder is free from diſeaſe, where a very large ſtone may not be extracted, without the uſe of any other inſtrument than the forceps, the urethra having firſt been ſufficiently dilated by means of the ſponge tents. For this purpoſe, the blades of the forceps need not be ſo thick and ſtrong as thoſe commonly employed." See Medico-Chirurgical Tranſactions, vol. i. p. 123—129.

Some ſurgeons have extracted ſtones from the female bladder as follows: the patient being placed in the poſition commonly adopted in the lateral operation, a ſtraight ſtaff, with a blunt end, is introduced into the bladder through the meatus urinarius. The ſurgeon then paſſes along the groove of the inſtrument the beak of a blunt gorget, which, becoming wider towards the handle, effects a part of the neceſſary dilatation. The ſtaff being withdrawn, and the handle of the gorget taken hold of with the left hand, the right fore-finger, with the nail turned downwards, is now introduced ſlowly along the concavity of the inſtrument. When the urethra and neck of the bladder have thus been ſufficiently dilated, the finger is withdrawn, and a ſmall pair of forceps paſſed into the bladder. The gorget is now removed, and the ſtone taken hold of and extracted. See Sabatier's Med. Opératoire, tom. ii. p. 103.

Notwithſtanding theſe favourable accounts of the practice of dilating the female urethra, for the purpoſe of removing calculi from the bladder, the generality of ſurgeons prefer an inciſion. It is certain, that ſome patients have found the method inſufferably painful and tedious. But the ſtrongeſt objection to the practice has ariſen from the incontinence of urine, which occaſionally follows any great diſtenſion of the urethra and neck of the bladder. Mr. Thomas believes, however, that this unpleaſant ſymptom is quite as often a conſequence of the operation of lithotomy, as now uſually performed. Medico-Chirurgical Tranſ. vol. i. p. 127.

Lithotomy on females is much more eaſy of execution, and leſs dangerous, than the ſame operation on the male ſex. It may be done in various ways; but the ſurgeons of the preſent time conſtantly follow the mode of making the requiſite opening by dividing the urethra and neck of the bladder. A ſtraight ſtaff, or director, is introduced through the meatus urinarius; the groove is turned obliquely downwards and outwards, in a direction parallel to the ramus of the left os pubis; and a gorget, or knife, is thus conducted into the bladder, and makes the neceſſary inciſion. Some operators prefer the lithotome caché, which, after being introduced, is opened as far as is deemed proper, and then drawn out with its edge turned obliquely outwards and downwards.

The French ſurgeons Louis and Flurant were the inventors of particular biſtouries for dividing both ſides of the female urethra at once; the inſtrument of the former effected this purpoſe, in paſſing from without inwards; that of the latter in paſſing from within outwards. Flurant's biſtoury bears ſome reſemblance in principle to Frère Côme's lithotome caché, or to the cutting forceps with which Franco uſed to divide the neck of the bladder. The reaſon aſſigned for theſe biſtouries is, that they will ſerve to make a freer opening for the paſſage of large ſtones, than can be ſafely made by cutting only in one direction. At preſent, however, they are never uſed. Were the ſtone known to be very large, Sabatier ſeems to prefer the apparatus altus.

A caſe may preſent itſelf, where the poſterior part of the bladder, drawn downwards by the weight of the ſtone, might diſplace a portion of the vagina, and make it protrude at the vulva, in the form of a ſwelling. Here, there would be no doubt of the propriety of cutting into the tumour, and taking out the foreign body contained in it. Rouſſet performed ſuch an operation, and Fabricius Hildanus, in a caſe where the ſtone had partly made its way into the vagina by ulceration, enlarged the opening, and ſucceſsfully extracted the extraneous body.

M. Méry once propoſed the method of making an opening into the poſterior part of the bladder, through the vagina, after introducing a common curved ſtaff; but the apprehenſion of urinary fiſtulæ made him abandon the project.

The exiſtence of extraordinary circumſtances may always render a deviation from the common modes of operating not only juſtifiable, but abſolutely neceſſary. Thus, Tolet met with a caſe, where a woman had a prolapſus of the uterus, with which the bladder was alſo diſplaced. In the latter viſcus, ſeveral calculi were perceived. An inciſion was made into it, and the ſtones extracted, after which operation

tion the diſplaced parts were reduced, and a cure ſpeedily enſued. Sabatier's Med. Opératoire, tom. ii. p. 107.

Treatment after the operation.—Whatever method of performing lithotomy has been ſelected, the great danger afterwards is the acceſs of inflammation of the bladder, peritoneum, and parts within the pelvis and abdomen in general. This alarming diſorder is the common cauſe of the numerous deaths which follow the ordinary modes of operating. The beſt method of preventing it is, as we have repeatedly explained, to make a free and ample opening for the paſſage of the ſtone, and to avoid all manual roughneſs and violence in the operation. But ſuppoſing tenderneſs and tenſion to have begun about the hypogaſtric region, attended with a ſmall frequent pulſe, pain over the abdomen, ſickneſs, thirſt, &c. not a moment muſt be loſt; as nothing will ſave the patient but the prompt and deciſive employment of antiphlogiſtic meaſures.

This much dreaded and fatal diſorder is particularly to be expected, when the patient is of a full ſanguineous habit, when the operation has been long and difficult, when much violence has been uſed in drawing out the ſtone, or when the bladder has been bruiſed by the reiterated introduction of the forceps, whether for the purpoſe of taking out one calculus, or ſeveral, or the fragment of one that has been broken. The perilous inflammation within the abdomen, however, may come on, even when the operation has been executed in the moſt expert and eaſy manner. The moſt effectual means againſt the complaint, are copious veneſection, and placing the patient for ſome hours in a warm bath. Theſe meaſures ſhould be taken immediately when the complaint is indicated by the leaſt pain and tenſion about the lower part of the abdomen. But, beſides bleeding and the warm bath, an endeavour ſhould be made to procure ſtools by giving the oleum ricini. When the patient is removed from the bath, a bliſter, or elſe leeches and fomentations, may be applied to the hypogaſtric region.

Were we to judge from the obſervations derived from the practice which it has fallen to our lot to ſee, we ſhould ſuppoſe, that the danger of hemorrhage after lithotomy has been generally exaggerated; for out of a vaſt many operations which we have been ſpectators of, there has not been one death from loſs of blood. But as wounding the pudendal artery may happen more frequently with ſome operators, whom we have had no opportunities of noticing, we are inclined to believe, not that the danger is unjuſtly magnified, but that the particular ſurgeons whom we have ſeen operate have generally eluded it.

In order to ſtop the bleeding from the trunk of the pudendal or pudic artery, authors adviſe us to introduce into the wound a cannula wrapt round with lint, for the purpoſe of making preſſure on the wounded part of the veſſel. Boyer is ſaid to have ſuppreſſed the hemorrhage in ſeveral inſtances, by introducing deeply into the wound a large doſſil, round which is tied a ligature, the ends of which, being ſeparated, are to be forcibly tied over a ſecond doſſil. The conſtriction tends to draw outwards the firſt doſſil, at the ſame time that it propels inwards that which is more external. Richerand, Noſographie Chir. t. iii. p. 533, edit. 2.

Secondary hemorrhages ſometimes occur in old debilitated ſubjects ſeveral days after the operation, and may prove fatal. They require the ſame treatment as the foregoing bleeding, though, notwithſtanding the moſt ſkilful compreſſion, the blood will often continue to ooze from day to day, till the patient falls a victim.

Were a patient to bleed profuſely from a wound of the pudendal artery, the veſſel might be taken up and tied by a good ſurgeon, which would be a much ſafer method than compreſſion. It ſeems, that in one example, Mr. Abernethy tied the trunk of this artery, where it paſſes along the inner ſurface of the tuberoſity and ramus of the iſchium. See Medical and Phyſical Journal, vol. ix. p. 393.

The dreſſings after the lateral operation are ſuperficial, and kept on with a T bandage. As ſeparating the thighs pulls aſunder the edges of the wound in the perineum, it is alſo cuſtomary to confine them together, when the patient is put to bed by means of a garter applied juſt above the knees.

LITHOXOS. See COLAPTICE.

LITHOXYLON, in *Mineralogy*, *Woodſtone*, *Holzſtein* of Werner, a ſpecies of ſiliceous genus in the arrangement of Kirwan. Its colour is generally blackiſh, or blueiſh-grey; the former frequently paſſing into the greyiſh-black, and the latter into the greyiſh white; and this from the light reddiſh-grey, into the blood or cochenille red. Seldom ochre yellow or mountain green; ſometimes reddiſh or yellowiſh-brown. Theſe colours commonly appear together in ſpots, blotches, or ſtripes, in the ſame ſpecimen. It always manifeſts its priſtine ſtate, either by its branchy form, or its knots or roots. Its ſurface, like that of the wood from which it originates, is ſometimes rough, ſometimes uneven, ſometimes coarſely ſtreaked in the direction of its length. Its internal luſtre, 1; its tranſparency, 1.2. Its fracture conchoidal; ſometimes imperfectly, or approaching to the fine ſplintery, ſometimes ſlaty; and generally, by its interlaced fibrous ſtructure, diſcovers its origin. Its fragments 3. Often ſplintery; its hardneſs, 10; the ſpecific gravity of different ſpecimens extended, upon Mr. Kirwan's trials, from 2.045 to 2.675. It is commonly, but not always, the ſubſtance of petrified wood. It often withers by expoſure to the atmoſphere. Its tranſitions are into quartz, calcedony, and, as ſome ſay, into pitch-ſtone or opal. Kirwan's El. of Min. vol. i.

LITHOXYLUM, in *Botany*, a term uſed by Linnæus to expreſs a heterogeneous ſubſtance on marine productions, which has fructifications in impreſſed points. See GORGONIA.

LITHOZUGIA, in *Natural Hiſtory*, the name of a genus of foſſils, of the claſs of the ſcrupi, compoſed of a cryſtalline matter a little debaſed, and containing within them various extraneous bodies, as pebbles, &c.

Dr. Woodward has ranked this genus among the pebbles, becauſe of the pebbles they contain; which is by no means a ſufficient reaſon for confounding two ſuch different foſſils; the lithozugia approaching to the nature of flint.

Mercatus and other naturaliſts have called the lithozugia, *oculati lapides*; and among Engliſh lapidaries they are known by the name of *pudding-ſtones*; which ſee.

LITHUANIA, in *Geography*, a country of Europe of conſiderable extent, anciently a ſeparate duchy, and afterwards united to Poland. Its capital was Vilna or Wilna, but its principal town was Grodno. When it was governed by its own ſovereigns under the title of Great-Dukes, a rivalry ſubſiſted between this duchy and the contiguous ſtates of Ruſſia and Poland, which was the occaſion of frequent conteſts. At ſo early a period as the 11th century, the Lithuanians, deſcended from the ancient ſtock of the *Slavonians* (ſee the article LETTES,) are enumerated by Neſtor in his chronicle, under the appellative Litva, among the nations tributary to the Ruſſian monarchy; nor could they find means to render themſelves an independent nation, till the time when dangerous inteſtine diviſions ſprang up in Ruſſia, under the ſucceſſors of Vladimir the Great, who died in the year 1015. At this time they were freed from the Ruſſian ſupremacy, enlarged their borders at the expence of their former maſters, and at length grew to be formidable to all their neighbours. In the year 1386, the great duke Ladiſlaus Jaghellon, or Yaghello, having eſpouſed the Poliſh queen Hadevige, and embraced the Chriſtian religion, was raiſed to the Poliſh throne, and reigned over both Poland and Lithuania. In conſequence of the union of the two countries, the conquered Ruſſian provinces devolved to this united kingdom. Ladiſlaus manifeſted the reality of his converſion, by endeavouring to propagate the Chriſtian doctrines among his idolatrous ſubjects in Lithuania; accordingly he cut down the hallowed groves, deſtroyed the oracular ſhrine, extinguiſhed the ſacred fire, and ſlew the ſerpents that were worſhipped as gods by his ſuperſtitious ſubjects. A belief univerſally prevailed among the people, that whoever profanely attempted to deſtroy theſe objects of their worſhip, would be ſtruck with inſtantaneous death; but the falſity of this tradition was evinced by the impunity of thoſe who were concerned in the ſuppoſed ſacrilege. The Lithuanians flocked in ſuch crowds to be converted, that the prieſts could only confer ſeparate baptiſm on perſons of diſtinction; but diſtributed the multitude in ranks, and ſprinkling them with water, gave one Chriſtian name to each rank without diſtinction of ſex. Ladiſlaus, having thus introduced the Chriſtian religion into Lithuania, nominated his brother Caſimir Skirgello governor of the duchy, and returned to Poland; but a civil war being excited by the ambition of Alexander, ſurnamed Vitoldus, and by the diſcontents of the people, ſtill attached to their Pagan rites, Lithuania was for ſome time a ſcene of tumult and hoſtility. At length, by a compromiſe in 1392, Vitoldus was appointed great duke, and Ladiſlaus contented himſelf with a nominal ſovereignty. In 1401 the nobles of Lithuania aſſembled at Vilna, and entered into an offenſive and defenſive alliance with the king and republic of Poland. In 1413, it was ſtipulated in a diet of Poles and Lithuanians, held in the town of Hrodlo, that, upon the demiſe of Vitoldus, the Lithuanians ſhould acknowledge no other great duke but the perſon who ſhould be appointed by the king, and with the agreement of the two nations; that if Ladiſlaus died without iſſue, the Poles ſhould elect no king without the conſent of Vitoldus and the Lithuanians, and that a diet, compoſed of repreſentatives from both nations, ſhould meet at Lublin or Panzow. From the demiſe of Vitoldus, who expired in 1439, in the 80th year of his age, the great dukes were ſometimes, in conformity to this compact, nominated by the kings of Poland, at other times in violation of it by the Lithuanians. At length Sigiſmund I. fortunately united in his perſon the two ſovereignties, and was ſucceeded in both by his ſon Sigiſmund Auguſtus. The connection between the two nations was, however, more an alliance than an union; but Sigiſmund Auguſtus having no children, and being the only ſurviving male heir of the Jaghellon family, planned the union of Poland and Lithuania, leſt upon his deceaſe the two nations ſhould again be governed by different princes. For this purpoſe a general diet was held at Lublin in 1569; and upon the ratification of the union, Sigiſmund Auguſtus renounced all hereditary right to Lithuania. From this time the ſame perſon was uniformly elected king of Poland and great duke of Lithuania, and the two nations were incorporated into one republic. Since this period, Lithuania has ſhared the fortunes of Poland; and with the gradual extinction of it, has likewiſe fallen a prey to her ſtronger and more powerful neighbours. At the partition of the year 1773, Lithuania furniſhed the whole ſhare which Ruſſia at that time obtained, and out of which the preſent vice-royalties of Mohilef and Polotſk are formed. In the ſubſequent partition of the year 1793, this grand duchy again loſt 1731 ſquare miles, and 850,000 ſouls, which now belong to the vice-royalty of Minſk; and in the final partition of the year 1795, the laſt remains of Lithuania alſo fell to the Ruſſian empire, of which at preſent the vice-royalties of Vilna and Slonimſk are formed. Theſe provinces of the Ruſſian empire are therefore thoſe in which Lithuanians reſide; but the number of people of which this nation conſiſts, can hardly be given with any degree of accuracy, as they are every where mingled with Ruſſians and Poles.

Lithuania was formerly a very woody country, but the greateſt part of it was uncultivated. However, under the tranquil reigns of Sigiſmund I. and his ſucceſſors, the woods were cleared in a great degree, and agriculture was encouraged. Pot-aſhes and wood-aſhes are made here in great abundance, and the country produces much corn. It alſo yields a great quantity of honey, from which are made the liquors called Lippitz, Mallinieck, and Mead. Its meadows and paſtures are fertile, and ſupply food for numerous flocks and herds. The wool is very fine. The lakes abound with fiſh; and the foreſts are the haunts of bears, wolves, wild boars, buffaloes, deer, and large flights of woodcocks. All ſorts of proviſions are cheap, but caſh is ſo ſcarce, that 10 *per cent.* is the common intereſt for money. The common people are generally vaſſals, and the nobility are numerous, but poor; ſome of the principal of them excepted, who poſſeſs princely revenues, occupy the chief poſts in the country, and live in great pomp and ſplendour.

LITHUANIA, *Little*, or *Pruſſian*, a province of Pruſſia, about 100 miles in length and half as much in breadth. This country was anciently over-run with thickets and woods; and in the year 1710, it was almoſt depopulated by a peſtilence. In 1720, Frederick William, at a great expence, induced many Switzers, French Proteſtants, Palatines and Franconians to ſettle here, and in 1732, 350,000 dollars were diſtributed among a freſh colony of 12,500 Saltzburgers. Theſe emigrants changed the face of the almoſt deſolated country, and its fertility appeared in the multitude and variety of its productions; ſuch as corn, horned cattle, numerous flocks of ſheep, excellent horſes, butter, cheeſe, &c. It afforded likewiſe plenty of fiſh and game. Several manufactures are alſo eſtabliſhed here, for coarſe and fine cloth, leather, &c. The ancient inhabitants of this country have a language peculiar to themſelves, into which the bible and ſome religious books have been lately tranſlated. The coloniſts of this country are engaged in various employments, to which their diſpoſition and habits incline them; and with reſpect to religion, the Switzers, French, and Franconians, are Calviniſts; ſo that there are 10 German and French reformed pariſhes, as they are denominated, in Little Lithuania. The reſt are Lutherans, intermixed with a few Papiſts. The principal towns are Memel, Tilſit, Ragnit, and Iſterburg.

LITIZ, or LEDITZ, a town, or rather village, of America, in Lancaſter county, Pennſylvania; ſituated in the townſhip of Warwick, containing about 50 houſes, and an elegant church with a ſteeple and bell, ſettled in 1757, and inhabited by the United Brethren, amounting, in 1787, to upwards of 300; eight miles N. of Lancaſter.

LITMUS, or LACMUS, in the *Arts*, is a blue pigment, or violet red paſte, formed from *archil*, which ſee. It is brought from Holland at a cheap rate; but may be prepared by adding quick-lime, and purified urine, or ſpirit of urine diſtilled from lime, to the archil previouſly bruiſed by grinding. The mixture, having cooled, and the fluid ſuffered to evaporate, becomes a maſs of the conſiſtence of a paſte, a paſte, which is laid on boards to dry, in ſquare lumps. The following is given as the exact proceſs for preparing it. (Nicholſon's Journal, 4to. vol. ii.) The lichen is firſt dried, cleanſed, and pulveriſed, in a mill like the oil-mill. The powder is then thrown into a trough, with one-half its weight of pearl-aſh, and moiſtened with a little human urine, and allowed to ferment. This fermentation is kept up for ſome time, by ſucceſſive additions of urine, till the colour of the materials changes firſt to red, then to blue. In this ſtate it is mixed with a third its weight of very good potaſh, and ſpread upon deep wooden trays till dry. A quantity of chalk is added at laſt, apparently for the mere purpoſe of increaſing the weight. It is only uſed in miniature paintings, and cannot be well depended on, becauſe the leaſt approach of acid changes it inſtantly from blue to red. This property renders the colour a valuable tint to the chemiſt, in detecting the preſence of uncombined acids. But when reddened by an acid, the blue is reſtored by an alkali: ſo that litmus may thus become a teſt both of acid and of alkali. The beſt litmus is very apt to change and fly. It is much employed for the purpoſe of giving a gloſs or finiſh to the more deep and permanent colours, by the dyers of ſilk, ſtuffs, and ribbons. Marble ſoaked with litmus-liquor imbibes it in ſome days, and becomes beautifully tinged with a colour, which will remain for a conſiderable time unimpaired.

LITOTES, Διτοτης, in *Rhetoric*. See LIPTOTES.

LITOWISCH, in *Geography*, a town of Poland, in Volhynia; 56 miles S.W. of Lucko.

LITRA, in *Ancient Coinage*. See LIBRA.

LITRE, or *Cubic Decimetre*, a French meaſure of capacity, equal to 60.02800 Engliſh cubic inches, or nearly $2\frac{1}{8}$ wine pints. See MEASURE.

LITRON, a meaſure for corn and dry commodities, in the old ſyſtem of France; 16 litrons being equal to a boiſſeau, each boiſſeau being = 780 Engliſh cubic inches, and 11 boiſſeaux = 4 Engliſh buſhels.

LITROTOND, in *Geography*, a town of Aſiatic Turkey, on the ſouth-weſt coaſt of Natolia. N. lat. 36° 51′. E. long. 27° 35′.

LITSCHAU, a town of Auſtria; 70 miles N.W. of Vienna. N. lat. 49° 48′. E. long. 14° 55′.

LITTAU, a town of Moravia, in the circle of Olmutz; 8 miles N.N.E. of Olmutz. N. lat. 49° 28′. E. long. 16° 59′.

LITTER, LECTICA, a kind of vehicle borne upon ſhafts, anciently eſteemed the moſt eaſy and genteel way of carriage.

Du Cange derives the word from the barbarous Latin, *lecteria*, *ſtraw* or *bedding for beaſts*. Others will rather have it come from *lectus*, *bed*, there being ordinarily a quilt and a pillow to a litter; in the ſame manner as to a bed.

Pliny calls the litter the traveller's chamber; it was much in uſe among the the Romans, among whom it was borne by ſlaves kept for that purpoſe; as it ſtill continues to be in the Eaſt, where it is called a *palanquin*.

The Roman *lectica*, made to be borne by four men, was called *tetraphorum*; that borne by ſix, *hexaphorum*; and that borne by eight, *octophorum*.

The invention of litters, according to Cicero, was owing to the kings of Bithynia: in the time of Tiberius they were become very frequent at Rome, as appears from Seneca; and even ſlaves themſelves were borne in them, though never by more than two perſons, whereas men of quality had ſix or eight.

LITTER, in *Agriculture*, a name applied to ſtraw, fern, or other dry ſubſtances, that are placed under horſes, cattle, &c. in the ſtables, cow-houſes, farm-yards, or other places for the purpoſe of keeping the animals clean, and the providing a large ſupply of manure. In this laſt view, all ſorts of dry materials ſhould be carefully collected, and ſtacked up for winter uſe. And it is of vaſt importance, in different views, to have it properly employed in foddering the cattle, as well as in littering them down in the ſtall and yards; as, without proper economy, much diſadvantage may ariſe to the farmer in the way of converting it into manure. See SOILING and FARM-YARD.

Merely as litter, wheat-ſtraw is always to be preferred for horſes; but for cattle and other animals, the other ſort of ſtraw, fern, &c. may anſwer equally well.

LITTERMORE, in *Geography*, an iſland on the coaſt of the county of Galway, Ireland. It is on the ſouth-eaſt of Kilkerran bay, and is about four miles long by two wide. N. lat. 53° 17′. W. long. 9° 40′.

LITTLE ALGONQUINS, Indians who inhabit near the Three Rivers, and can raiſe about 100 warriors.

LITTLE *Bairam*. See BAIRAM.

LITTLE *Britain*, a poſt-town of America, in Orange county, New York; 294 miles from Waſhington.—Alſo, a townſhip in Lancaſter county, Pennſylvania, containing 1365 inhabitants.—Alſo, a townſhip in Cheſter county, in the ſame ſtate,

LITTLE *Capſtan*. See CAPSTAN.

LITTLE *Compton*, in *Geography*, a townſhip in Newport county, Rhode iſland, containing 1577 inhabitants, and affording greater quantities of meat, butter, cheeſe, vegetables, &c. than any other town of its ſize. The inhabitants, who are induſtrious, manufacture linen and tow cloth, flannels, &c. of an excellent quality, and in conſiderable quantities for ſale.

LITTLE *Creek*, a town of America, in Kent county, Delaware, containing 1908 inhabitants.—Alſo, a town in Suſſex county, Delaware, containing 2164 inhabitants.

LITTLE *Harbour*. See PISCATAQUA.—Alſo, a bay in the ſtraits of Magellan, on the coaſt of Patagonia; 5 miles N.W. of Bachelor's river.

LITTLE *Iſland*, or *Little Salvador*, one of the ſmaller Bahama iſlands. N. lat. 23° 46′. W. long. 75° 26′.—Alſo, an iſland in the river Lee, in Ireland, about three miles in circumference; 6 miles E. of Cork.

LITTLE *Maſs*. See MASS.

LITTLE *River*, in *Geography*, a beautiful and rapid river of America, in Georgia, which, at its confluence with Savannah river, is about 50 yards wide.—Alſo, a river which partly ſeparates North and South Carolina.—Alſo, a plantation in Kennebeck county, Maine.

LITTLE *Sodus*, a harbour of lake Ontario; 15 miles S. of Oſwego.

LITTLEBOROUGH, a town on the weſt coaſt of the iſland of Nevis; 2 miles N. of Charleſtown.

LITTLETON, ADAM, in *Biography*, a learned philologiſt, was born in 1627 at Hales-Owen, in Shropſhire, of which place his father was vicar. He was educated at Weſtminſter, under Dr. Buſby; and in 1644 was admitted a ſtudent of Chriſt's college, Oxford. He was, on account of his principles, ejected by the parliamentary viſitors in 1648, and was under the neceſſity of obtaining a living as uſher at different ſchools. At the reſtoration, he was appointed ſecond maſter of Weſtminſter ſchool, king's chaplain in ordinary; and in 1674, having already obtained his doctor's degree, he was inducted to the rectory of Chelſea. This preferment was followed by being appointed a prebendary of Weſtminſter, and afterwards ſub-dean. He died on the 30th of June 1694, leaving behind him the character of an amiable man, and very conſiderable ſcholar. He was converſant in the Hebrew, Chaldaic, and Arabic languages; and was converſant with the higher parts of mathematics. He publiſhed many works in divinity and philology, but is chiefly known for his "Latin Dictionary," which was in general uſe in our ſchools till that of Ainſworth was publiſhed. He had received a grant of king Charles II. to ſucceed Dr. Buſby, as head meaſter of Weſtminſter ſchool; but death prevented the execution of the king's intention.

Littleton, *Sir* **Thomas**, an Engliſh lawyer and judge, who flouriſhed in the fifteenth century, was eldeſt ſon of Thomas Weſtcote, eſq. of Devonſhire, by the heireſs of Littleton, of Frankley in Worceſterſhire, whoſe name he aſſumed. He was regularly educated for the law; and, in the reign of Henry VI., he was made judge of the marſhalſea court and king's ſerjeant, and in 1455 went the northern circuit as judge of the aſſiſe. In 1466 he was appointed one of the judges of the common pleas, and, a ſhort time after, was created a knight of the Bath. He died in 1481, leaving three ſons, from whom many conſiderable families are deſcended. He was author of a valuable work, entitled "Tenures and Titles by which Eſtates were anciently held in England." It was written in French, and a tranſlation of it, with a commentary, forms the firſt book of Coke's "Inſtitutes." Sir Thomas, during the troubles and confuſions of the times, ſo comported himſelf, as to enjoy the favour of both the contending ſovereigns; and, at the ſame time, acquired the eſteem of all, for his great ſkill in the laws of England.

Littleton, Edward, diſtinguiſhed for his great knowledge in the common law, ſon of ſir Edward, a Welſh judge, was born in 1589, and purſued his college exerciſes in Chriſt church, Oxford, from whence he removed to the Inner Temple, to purſue the ſtudy of the law. He was an active member of parliament in the year 1628, and, together with ſir Edward Coke and ſir Dudley Digges, carried up the Petition of Right from the Commons to the Lords. He was alſo a leading manager in the accuſation againſt the duke of Buckingham, in which his judicious conduct obtained for him the good opinion of the prince and people. He ſucceeded his father as Welſh judge, and was choſen recorder of London. In 1634 he was made by Charles I. ſolicitor-general, and knighted; in 1639 he was ſworn lord chief juſtice of the common pleas; and, in the following year, he was advanced to be lord keeper of the great ſeal of England, and called to the houſe of peers by the title of lord Littleton. He afterwards loſt the favour of the king, though it is believed without reaſon, which he could never after regain. He died in Auguſt 1645, at Oxford, where he was buried on the north ſide of the choir in the cathedral of Chriſt church, and had a funeral oration pronounced over him by Dr. Henry Hammond. He publiſhed a book of Reports of Caſes in the Courts of Common Pleas and Exchequer, from the ſecond to the eighth of Charles I.; ſome ſpeeches in parliament, ſeveral arguments and diſcourſes. Biog. Brit.

Littleton, in *Geography*, a poſt-town of America, in Middleſex county, Maſſachuſetts, 28 miles N.W. of Boſton; containing 904 inhabitants.—Alſo, a poſt-town in Grafton county, New Hampſhire, incorporated in 1784, and containing 381 inhabitants.—Alſo, a townſhip, now called *Waterford*, in Caledonia county, Vermont, on the weſt ſide of Connecticut river, containing 565 inhabitants.

Littleton's *Iſland*, a ſmall iſland in the Florida ſtream. N. lat. 24° 42′. W. long. 81° 40′.

LITTORAL Shells, among writers of *Natural Hiſtory*, are ſuch ſea-ſhells as are always found near the ſhores, and never far off in the deep.

Thoſe which are found in the bottom of the ſea, remote from the ſhore, are called *pelagian*.

LITTORELLA, in *Botany*, the diminutive of *littus*, a ſhore, this plant being generally found in the neighbourhood of lakes or pools. Indeed its Engliſh name, Shore-weed, is alſo expreſſive of its place of growth. Linn. Mant. 160. Schreb. 629. Willd. Sp. Pl. v. 4. 330. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1011. Ait. Hort. Kew. ed. 1. v. 3. 335. Juſſ. 90. Lamarck Illuſtr. t. 758.—Claſs and order, *Monoecia Tetrandria*. Nat. Ord. *Plantagines*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth of four leaves, erect. *Cor.* of one petal; tube the length of the calyx; limb four-cleft, erect, permanent. *Stam.* Filaments four, thread-ſhaped, very long, inſerted into the receptacle; anthers heart-ſhaped.

Female on the ſame plant. *Cal.* none. *Cor.* of one petal, conical, permanent, its mouth unequally three-cleft. *Piſt.* Germen oblong; ſtyle thread-ſhaped, very long; ſtigma acute. *Peric.* none, except the permanent corolla. *Seed* a nut of one cell.

Eſſ. Ch. Male, Calyx four-leaved. Corolla of one petal, four-cleft. Stamens very long.

Female, Calyx none. Corolla of one petal, unequally three-cleft. Style thread-like, very long. Nut of one cell.

1. L. *lacuſtris*. Plantain Shore-weed. Linn. Mant. 295. Sm. Fl. Brit. 1011. Engl. Bot. t. 468. (Plantago uniflora; Linn. Sp. Pl. 167. Fl. Dan. t. 170.)—A native of the ſhores of lakes in various parts of Europe, and of marſhy ſandy ſpots in Great Britain, but not very common. It flowers in June. *Root* perennial, ſpindle-ſhaped. *Herb* ſmooth, ſtemleſs. *Leaves* linear, entire, convex underneath. *Male flowers* on ſtalks, ſolitary, erect, whitiſh, reſembling thoſe of Plantain: *female ones* radical, ſeſſile, having an erect, prominent, thread-ſhaped ſtyle.

The whole habit of this curious genus is that of a *Plantago*, from which however it is ſufficiently diſtinct on account of its fruit being a ſingle ſeed or nut. It was originally ſeparated from that genus, by Bergius, in the Stockholm Tranſactions for 1768. The Rev. Mr. Williams of Shropſhire has found this plant occaſionally to vary with hairy leaves.

LITURGY, denotes all the ceremonies in general belonging to divine ſervice.

The word comes from the Greek λειτουργια, *ſervice, public miniſtry*, formed of λειτος, *public*, and εργον, *work*.

In a more reſtrained ſignification, liturgy is uſed among the Romaniſts to ſignify the maſs; and among us the common-prayer.

All who have written on liturgies agree, that in the primitive days, divine ſervice was extremely ſimple, only clogged with very few ceremonies, and conſiſting of but a ſmall number of prayers; but, by degrees, they increaſed the number of external ceremonies, and added new prayers, to make the office look more awful and venerable to the people. At length things were carried to ſuch a pitch, that regulation became neceſſary; and it was found proper to put the ſervice, and the manner of performing it, into writing; and this was what they called a liturgy.

Liturgies have been different at different times, and in different countries. We have the liturgy of St. Chryſoſtom, that of St. Peter, of St. James, the liturgy of St. Baſil, the Armenian liturgy, the liturgy of the Maronites, of the Cophtæ, the Roman liturgy, the Gallican liturgy, the

Engliſh liturgy, the Ambroſian liturgy, the Spaniſh and African liturgies, &c.

In the more early ages of the church, every biſhop had a power to form a liturgy for his own dioceſe; and if he kept to the analogy of faith and doctrine, all circumſtances were left to his own diſcretion. Afterwards the practice was for the whole province to follow the ſervice of the metropolitan church, which alſo became the general rule of the church: and this Lindwood acknowledges to be the common law of the church; intimating, that the uſe of ſeveral ſervices in the ſame province, which was the caſe in England, was not to be warranted but by long cuſtom. Gibſ. 259.

The liturgy of the church of England was compoſed in the year 1547, and eſtabliſhed in the 2d year of king Edward VI. by ſtat. 2 & 3 Edw. VI. cap. 1.

In the fifth year of this king it was reviewed; becauſe ſome things were contained in that liturgy, which ſhewed a compliance with the ſuperſtition of thoſe times, and ſome exceptions were taken againſt it by ſome learned men at home, and by Calvin abroad. Martin Bucer was conſulted, and ſome alterations were made in it, which conſiſted in adding the general confeſſion and abſolution, and the communion to begin with the ten commandments. The uſe of oil in confirmation, and extreme unction were left out, and alſo prayers for ſouls departed, and what tended to a belief of Chriſt's real preſence in the euchariſt. This liturgy, ſo reformed, was eſtabliſhed by the act of 5 & 6 Edw. VI. cap. 1. However, it was aboliſhed by queen Mary, who enacted that the ſervice ſhould ſtand as it was moſt commonly uſed in the laſt year of the reign of king Henry VIII. The liturgy of 5 & 6 Edw. VI. was re-eſtabliſhed with ſome few alterations and additions, by 1 Eliz. cap. 2. All the biſhops preſent diſſented both in this and the former acts; and, therefore, the expreſſion "lords ſpiritual" doth not occur in either of them. (Gibſ. 268.) Some farther alterations were introduced, in conſequence of the review of the Common Prayer Book, by order of king James, in the firſt year of his reign; particularly in the office of private baptiſm, in ſeveral rubricks and other paſſages, with the addition of five or ſix new prayers and thankſgivings, and all that part of the catechiſm which contains the doctrine of the ſacraments. The book of Common Prayer, ſo altered, remained in force from the firſt year of king James to the fourteenth of Charles II. But the laſt review of the liturgy was in the year 1661, and the laſt act of uniformity enjoining the obſervance of it, is 13 & 14 Car. II. cap. 4. (See Common *Prayer*.) Many applications have been ſince made for a review, but hitherto without ſucceſs. See Free and Candid Diſquiſitions relating to the Church of England, &c. 8vo. Lond. 1749.

We ſhall here ſubjoin ſome pertinent remarks on liturgies by archdeacon Paley, together with ſome additional reflections. Liturgies, or preconcerted forms of public devotion, being neither enjoined in ſcripture, nor forbidden, there can be no good reaſon for receiving or rejecting them, but that of expediency; which expediency is to be deduced from a compariſon of the advantages and diſadvantages attending this mode of worſhip with thoſe which uſually accompany extemporary prayer. The advantages of a liturgy are theſe: 1. That it prevents abſurd, extravagant, or impious addreſſes to God, which, in an order of men ſo numerous as the ſacerdotal, the folly and enthuſiaſm of many muſt always be in danger of producing, where the conduct of the public worſhip is entruſted, without reſtraint or aſſiſtance, to the diſcretion and abilities of the officiating miniſter. On the other hand, the advocate for free prayer might allege, that the caſes to which the ingenious author refers are of the extreme kind, that are not likely often to occur; that a miniſter who is capable of addreſſing a congregation acceptably and uſefully, would not be in danger of offending in the manner here ſuppoſed, when he conducted their ſocial devotion, more eſpecially as he would conceive it to be his duty to make previous preparation for the one ſervice as well as the other; that the mode of performing public worſhip muſt be left to the choice and approbation of thoſe who concur in it; that the occaſional perverſion and abuſe of a privilege cannot be juſtly pleaded againſt the uſe of it; and that if the evil were greater than it is, there is no method of avoiding it, but by the impoſition of preconcerted liturgies, which would encroach on liberty in the province of religion. Eſtabliſhed liturgies, it might be ſaid, are not eaſily accommodated to the ſentiments of the worſhipper, who diſbelieves the creed on which they are founded; and they muſt lead him to the avowal of principles, and to the uſe of language, which his judgment diſapproves. If every officiating miniſter be allowed to adopt his own mode of conducting ſocial worſhip, whether it be by extempore prayer, or by forms, for each of which he has made previous preparation, he is not likely to give offence to thoſe who join with him.

Our author further obſerves, 2. That a liturgy prevents the *confuſion* of extempore prayer, in which the congregation being ignorant of each petition before they hear it, and having little or no time to join in it after they have heard it, are confounded by their attention to the miniſter, and to their own devotion. The devotion of the hearer is neceſſarily ſuſpended, until a petition be concluded; and before he can aſſent to it, or properly adopt it, that is, before he can addreſs the ſame requeſt to God for himſelf, and from himſelf, his attention is called off to keep pace with what ſucceeds. But the advocate for free prayer will naturally enquire, if this be not the caſe, in a greater or leſs degree, in every continued ſervice? If he has the words before him, which he uſes in his devotion, does he dwell on a ſingle ſentence as ſoon as the officiating miniſter utters it? Is not his attention drawn on to ſucceeding parts of the prayer that is pronounced, as ſoon as they are delivered? But in neither caſe is his mind kept long in a ſtate of ſuſpence; and he has this advantage, that whilſt he is joining in exerciſes of devotion with the miniſter of his choice, he is not likely to heſitate in concurring with him. As to the novelty with which he expects to be gratified, this may probably be more likely to excite his attention and impreſs his heart, than a recurrence of ſentiments and expreſſions that are familiar to him, and which long-continued uſe will prevent from intereſting and fixing the (perhaps) wandering mind. *Joint* prayer, it is further ſaid by the learned archdeacon, which, among all denominations of Chriſtians, is the declared deſign of "coming together," is prayer in which all *join*; and not that which one alone in the congregation conceives and delivers, and of which the reſt are merely hearers. This objection, ſays our author, ſeems fundamental, and holds even where the miniſter's office is diſcharged with every poſſible advantage and accompliſhment. But in the uſe of preconcerted and eſtabliſhed liturgies, are not all beſides the officiating miniſter hearers, unleſs they concur in thoſe reſponſes, which have been obſerved in many inſtances to produce confuſion, and to render devotion a kind of mechanical buſineſs? The advocate for extempore prayer will allege, that he is not leſs capable of joining in a worſhip, conducted by a miniſter who uſes words, ſuggeſted at the moment, than in that which is performed by a recital of words previouſly written or printed. The objection to this mode of public worſhip, founded on the labouring recollection, and embarraſſed or tumultuous delivery of many extempore ſpeakers, evinces the neceſſity of talents for the diſcharge of this part of public duty, and of previous preparation, but does not prove that the adoption of a liturgy is either moſt expedient or moſt uſeful when extempore prayer is properly performed ; and it is preſumed, that perſons who are accuſtomed to exerciſes of devotion will acquire a facility in the performance of them, which will, in a great degree, obviate the objection now ſtated, and prevent the pain that would be given to the ſerious part of a congregation, or the profane diverſion which might be occaſioned by the levity of the other part.

The advantages of a liturgy, our author candidly allows, are connected with two principal inconveniences ; *firſt*, that forms of prayer compoſed in one age become unfit for another by the unavoidable change of language, circumſtances and opinions : *ſecondly*, that the perpetual repetition of the ſame form of words produces wearineſs and inattentiveneſs in the congregation. Both theſe inconveniences, however, are in their nature vincible. Occaſional reviſions of a liturgy may obviate the firſt, and devotion will ſupply a remedy for the ſecond ; or, as our author thinks, they may both ſubſiſt in a conſiderable degree, and yet be outweighed by the objections which are inſeparable from extemporary prayer. Nevertheleſs, this is a conceſſion, which will not be admitted by the advocates of the latter mode of worſhip ; nor adverting to paſt experience, ſince the year 1661, will they lay much ſtreſs on occaſional reviews of the liturgy.

How far the Lord's prayer is a precedent, as well as a pattern, for forms of prayer, is a queſtion, concerning which writers, who have directed their attention to this ſubject, are not agreed.

Archdeacon Paley ſpecifies the following properties as requiſite in a public liturgy ; *viz.* that it be compendious ; that it expreſs juſt conceptions of the divine attributes ; that it recite ſuch wants as a congregation are likely to feel, and no other ; and that it contain as few controverted propoſitions as poſſible. As to the firſt property, he obſerves, that it would be no difficult taſk to contract the liturgies of moſt churches into half their preſent compaſs ; and yet retain every diſtinct petition, as well as the ſubſtance of every ſentiment, which can be found in them. Although our author does not admit the propriety of ſtudying brevity too much, he is of opinion, that the too great length of church ſervices is unfavourable to piety. It begets in many an early and unconquerable diſlike to the public worſhip of their country or communion. They come to church ſeldom ; and enter the doors when they do come under the apprehenſion of a tedious attendance, which they prepare for at firſt, or ſoon after relieve, by compoſing themſelves to a drowſy forgetfulneſs of the place and duty, or by ſending abroad their thoughts in ſearch of more amuſing occupation. Although there may be ſome few of a diſpoſition not to be wearied with religious exerciſes, yet, where a ritual is prolix, and the celebration of divine ſervice long, no effect is in general to be looked for, but that indolence will find in it an excuſe, and piety be diſconcerted by impatience. It might further be obſerved, that the extent of our eſtabliſhed liturgy does not leave time ſufficient for public inſtruction ; that the attention is fatigued before this part of our public ſervice commences ; and that exceſs in our public diſcourſes, which admit of variety, is more excuſable than the ſame fault in our devotional exerciſes, during which the attention ought to be kept alive, and the underſtanding and heart properly engaged. Our author remarks, that the length and repetitions complained of in our liturgy are not ſo much the fault of the compilers, as the effect of uniting into *one* ſervice, what was originally, but with very little regard to the conveniency of the people, diſtributed into *three*. Accordingly we obſerve, with the authors of the "Free and candid Diſquiſitions," that the Lord's prayer in particular is enjoined to be publicly uſed every Lord's day in our ordinary ſervice, when there is no communion, no leſs than ſeven times, *viz.* five times in the morning and twice in the afternoon : and when there is a communion, and alſo afternoon ſermon or lecture, then nine times : and if the office of infant baptiſm (to ſay nothing of that of adults), and the other of churching of women, happen to come in, as they may and do ſometimes, both morning and afternoon, then thirteen times. The "Gloria Patri" is introduced commonly, and moſt uſually, ſeven or eight times ; not unfrequently nine or ten ; and may alſo occur eleven times, in the courſe of our morning ſervice only. Notwithſtanding that dread of innovation, in religion, which, ſays archdeacon Paley, ſeems to have become the *panic* of the age, few, as he ſuppoſes, would be diſpleaſed with ſuch omiſſions, abridgments, or change in the arrangement, as the combination of ſeparate ſervices muſt neceſſarily require, even ſuppoſing each to have been faultleſs in itſelf. If, together with theſe alterations, the epiſtles and goſpels, and collects which precede them, were compoſed and ſelected with more regard to unity of ſubject and deſign ; and the pſalms and leſſons either left to the choice of the miniſter, or better accommodated to the capacity of the audience, and the edification of modern life ; the church of England would be in poſſeſſion of a liturgy, in which thoſe who aſſent to her doctrines would have little to blame, and the diſſatisfied muſt acknowledge many beauties. The ſtyle throughout is excellent ; calm, without coldneſs ; and, though every where ſedate, oftentimes affecting. The pauſes in the ſervice are diſpoſed at proper intervals ; the tranſitions from one office of devotion to another, from confeſſion to prayer, from prayer to thankſgiving, from thankſgiving to "hearing of the word," are contrived, like ſcenes in the drama, to ſupply the mind with a ſucceſſion of diverſified engagements. As much variety is introduced alſo in the form of praying as this kind of compoſition ſeems capable of admitting.

The *ſecond* property of a liturgy, *viz.* that it ſhould expreſs juſt conceptions of the divine attributes, is an article deſerving particular care. The popular notions of God are formed, in a great meaſure, from the accounts which the people receive of his nature and character in their religious aſſemblies. An error here becomes the error of multitudes : and as it is a ſubject in which almoſt every opinion leads the way to ſome practical conſequence, the purity or depravation of public manners will be affected, among other cauſes, by the truth or corruption of the public forms of worſhip. The *third* requiſite of a liturgy is that it recite ſuch wants as the congregation are likely to feel, and no other. It were therefore to be wiſhed that every part of a liturgy were perſonally applicable to every individual in the congregation ; and that nothing were introduced to interrupt the paſſion, or damp a flame which it is not eaſy to rekindle. Upon this principle, the *ſtate-prayers* in our liturgy ſhould be fewer and ſhorter. The *ſtate-ſtyle* likewiſe ſeems unſeaſonably introduced into theſe prayers, as ill according with the annihilation of human greatneſs, of which every act that carries the mind to God preſents the idea. It is required, *fourthly*, that a liturgy contain as few controverted propoſitions as poſſible. Why, ſays our author, ſhould every poſition which a church maintains be woven with ſo much induſtry into her forms of public worſhip ? Some are offended, and ſome are excluded ; this is an evil in itſelf, at leaſt to *them* : and what advantage or ſatisfaction can be derived to the *reſt* from the ſeparation of their brethren, it is difficult to imagine: unleſs it were a duty to publiſh our ſyſtem of polemic divinity, under the name of making confeſſion of our faith every time we worſhip God; or a ſin, to agree in religious exerciſes with thoſe from whom we differ in ſome religious opinions: indeed, where one man thinks it his duty conſtantly to worſhip a being whom another cannot, with the aſſent of his conſcience, permit himſelf to worſhip at all, there ſeems to be no place for comprehenſion, nor any expedient left but a quiet ſeceſſion. All other differences may be compromiſed by ſilence. If ſects and ſchiſms be an evil, they are as much to be avoided by one ſide as the other. If ſectaries are blamed for taking unneceſſary offence, eſtabliſhed churches are no leſs culpable for unneceſſarily giving it: they are bound at leaſt to produce a command, or a reaſon of equivalent utility, for ſhutting out any from their communion, by mixing with divine worſhip, doctrines which, whether true or falſe, are unconnected, in their nature, with devotion. Paley's Principles of Moral and Political Philoſophy, vol. ii. chap. 5. See Prayer.

Of all the forms which Chriſtianity has taken in different parts of the world, of all the ſects which refuſe communion, with regular eſtabliſhments, muſic, or rather chanting, has been the language of devotion. It has been ſarcaſtically aſked, whence this impulſe to *cry aloud* originated; was it from the thundering muſic of the ſingers of Joſhua round Jericho, the ſweet ſtrains of the harp of David, the pompous and proud clangor and vociferating of the myriads of muſicians at the temple of Solomon, or the pious chant of the canticle which Jeſus Chriſt and his apoſtles ſung at the firſt inſtitution of prayer, that we derive our choirs, hymns, pſalms, and ſpiritual ſongs, which in every communion of Chriſtians conſtitute, and always have conſtituted, a conſiderable part of the public worſhip regulated by liturgies? We have no doubt but that the primitive Chriſtians, when their religion was founded on that of the Jews, (at leaſt as far as the belief and worſhip of one God,) in oppoſition to Paganiſm and idolatry, ſung the Pſalms of David, which they had adopted, in imitation of the royal pſalmiſt and his nation.

But there was no Pagan temple, or ſacrifice at an altar, without muſic, and at preſent, even the ſavages of America honour their divinities with ſinging. Indeed ſongs, of which the ſubject and poetry correſpond with the rites and ceremonies of the Pagans, conſtituted all their liturgies, to the exact celebration of which it is well known they were ſcrupulouſly attached. It is true that the Chriſtians differ very much in their muſical taſtes. The Quakers have no liturgy; they wait till the ſpirit moves them to ſpeak, and never ſing; they only ſigh and groan. Calvin ſtript muſic of harmony and meaſure, and allowed of nothing but uniſonous and ſyllabic ſinging in the conventicles, without the aſſiſtance of that *box of whiſtles*, as the Scotch reformers uſed to ſtyle the organ. The modern methodiſts like light, airy, and familiar muſic ſo much better than ſolemn ſtrains of ſupplication, that they admit ballad and barrel-organ tunes out of the ſtreet to be adapted to their hymns. The muſic à cappella, in the cathedral ſervice of the Roman Catholics and Proteſtants of the ſixteenth and ſeventeenth centuries, ſeems the moſt ſolemn and reverend ſpecies of muſic with which to addreſs the divinity; at leaſt it is the moſt grateful to cultivated ears. In pariſh churches, under the guidance of a powerful organ, or a judicious chantor, pſalmody in parts, provided ſome reſpect were paid to accent, and diſtinction were made between long and ſhort ſyllables, as in the 104th pſalm and other melodies in triple-time, would ceaſe to be abſurd and ridiculous to lovers of muſic, and rendered a gratification, inſtead of a torture, to cultivated ears.

LITVINTZOVA, in *Geography*, a town of Ruſſia, in the government of Irkutſk; 36 miles S. of Ilimſk.

LITUS, in the *Materia Medica*, the ſame as *liniment*; which ſee.

LITUUS, among *Medaliſts*, the ſtaff or wand twiſted round at the top, uſed by the augurs, made in the form of a crozier, and the badge of the augurſhip.

We frequently ſee it on medals, along with other pontifical inſtruments. Aulus Gellius ſays, it was bigger in the place where it was crooked than elſewhere. In ſome coins of Nero the lituus appears at his breaſt; and from badly preſerved coins has been taken by ſome medallic writers for a ſerpent.

Lituus, in *Natural Hiſtory*, a name given to a genus of ſhells of the claſs of the polythalamii, or thoſe which conſiſt of ſeveral concamerations or chambers, parted from one another by ſhelly diaphragms, and communicating with one another by means of a ſiphunculus, which runs through the whole length of the ſhell. To this general character of the claſs, it is to be added, that the lituus is always a conic ſhell, running in a ſtraight line from the mouth, through a great part of the length, and from the end of this ſtraight part to the extremity, twiſting into the ſhape of a cornu ammonis, or ſpiral ſhell of that kind.

It is thus named from its reſembling the inſtrument called lituus among the ancients. The ſtony matter often found caſt in this ſhell, and reſembling all its lineaments, is called by authors *lituites*, as thoſe ſtones formed in the pecten, pectinites, and thoſe in the echini marini echinitæ. See Conchology.

Lituus, in *Roman Antiquity*. The Romans had a crooked military muſical inſtrument called a *lituus*, in the form of the augural ſtaff, whence it had its name. It was a ſpecies of clarion, or octave trumpet, made of metal, and extremely loud and ſhrill, uſed for the cavalry, as the ſtraight trumpet was for the foot. Horace diſtinguiſhes it from the *tuba*, or trumpet.

> "Multos caſtra juvant, et lituo tubæ
> Permiſtus ſonitus, ——— Od. i. 23.

as Claudian does from the flute:

> "Tibia *pro* lituis, et pro clangore tubarum
> Molle lyræ, fuſtumque canant."

On our muſic plates are engraved a double lituus and a ſtraight trumpet, from an ancient bas-relief in the Vitaleſchi palace at Rome, repreſenting a ſacrifice: as is a genuine ancient metalline lituus, now in the poſſeſſion of the right honourable ſir Joſeph Banks, K.B. and preſident of the Royal Society. It was found with many other antiquities, both Roman and Anglo Saxon, in clearing the bed of the river Witham, near Tatterſhall, in Lincolnſhire, 1761, and is perhaps the only inſtrument of the kind that is now extant. It is a long narrow tube, with a ſwelling curve at the end, like the double lituus, but reſembling ſtill more an inſtrument ſculptured on the baſe of Trajan's pillar at Rome. It is neatly made of very thin braſs, with three joints or pieces, like German flutes, and has been well gilt. Its length is upwards of four feet, though the upper end has been evidently broken off.

An inſtrument of this kind, made of caſt braſs, was found in digging a well, near Battle in Suſſex, and was then filled with ſmall ſhells. We have an engraving of it in Groſe's

Military Antiquities, vol. ii. A ſimilar trumpet is engraved in Montfaucon's Roman Antiquities.

This inſtrument frequently appears on ancient medals as a ſymbol of war, and is terminated with the head of a boar, and ſometimes with that of a ſnake, as on an ancient family medal of Albinus, ſtruck during the time of the republic, between the firſt Punic war and the reign of Auguſtus.

LITYERSA, the ſong of the reapers, in the *Ancient Muſic*. Theocritus, Apollodorus, Julius Pollux, Suidas, and others, mention this ſong, and call it Lityerſa, from Lytiurſas, the natural ſon of Midas; a rude and ferocious prince, who obliged ſtrangers to work with him in the fields at harveſt-time, and thoſe who were too feeble and unable to work, he put to death. Hercules killed him in the life-time of his father.

Julius Pollux ſays that this ſong was mournful, and ſung round the ſhearers, to conſole Midas for the death of his ſon.

LITZENDORF, in *Geography*, a town of Bavaria, in the biſhopric of Bamberg; 6 miles E.N.E. of Bamberg.

LIVADIA, a province of European Turkey, bounded on the N. by Theſſaly, on the E. by the Archipelago, on the S. by the gulf of Lepanto, which ſeparates it from the Morea, and the gulf of Egina, and on the W. by the Mediterranean; 180 miles long from N.W. to S.E., and about 35 miles in its medial breadth. This province comprehends what was properly called Greece (ſee GRÆCIA *Propria*); and the mountains, ſo much celebrated by the ancients, *viz.* Parnaſſus, Helicon, and Cythæron. The places that are now moſt noted in it are Lepanto, Livadia, and Athens.

LIVADIA is alſo a large, populous, commercial town, in the province of the ſame name, ſituated near the gulf of Lepanto, and built round a mountain terminating in a peak, and on which is a caſtle; 28 miles N. of Corinth. N. lat. 38° 37'. E. long. 23 54'.

LIVADOSTA, a town of Livadia, on the E. extremity of the gulf of Lepanto; 20 miles S.E. of Livadia..

LIVAROT, a town of France, in the department of the Calvados, and chief place of a canton, in the diſtrict of Liſieux; 8 miles S.S.W. of Liſieux. The place contains 1210, and the canton 11,279 inhabitants, on a territory of 195 kiliometres, in 29 communes.

LIUBIM, a town of Ruſſia, in the government of Jaroſlavl; 40 miles N.E. of Jaroſlavl. N. lat. 58° 55'. E. long. 40° 50'.

LIUBITCH, a town of Ruſſia, in the government of Tchernigov, on the Dnieper; 20 miles W. of Tchernigov. N. lat. 51° 22'. E. long. 26° 44'.

LIUDER, a town of Sweden, in the province of Smaland; 31 miles W. of Calmar.

LIVE CAVES, in *Mining*, a phraſe uſed by many people to expreſs ſuch caverns in the earth as have but little communication with the external air, and are found to abound with mineral productions. The workers in the lead-mines on Mendip-hills diſtinguiſh the numerous caverns in thoſe places into the *live* or *quick* caves, and the *dead* caves; the latter are ſuch as admit the air into them two or three ways, and are barren of any thing valuable; the others have only one paſſage, and that but narrow and winding, and generally lie at great depths. Theſe abound in numerous elegant productions. They almoſt always contain ore in ſome form or other, and uſually abound in elegant ſpars. Mr. Beaumont mentions one of theſe in the Philoſophical Tranſactions, which lay at thirty-five fathom perpendicular depth, in which there was found a fine liver-coloured earth, of the nature of bole armenic, which in many places ſhoot up in a wonderful manner in a ſort of ſpires of the height of three or four inches, formed with ridges and furrows, and uſually covered with ſpar at the top; ſometimes all the way down, to the bed of earth. Phil. Tranſ. N° 129.

LIVE *Ever*, in *Botany*. See ORPINE.

LIVE *in Idleneſs*. See VIOLET.

LIVE *Hedges*, in *Rural Economy*, ſuch as are conſtituted of living materials, ſuch as white-thorn plants, &c. See FENCE.

LIVE-*Stock*, in *Agriculture*, is a term which ſignifies all that ſort of animal ſtock which is raiſed or kept upon a farm, either for the purpoſe of uſe or profit. It comprehends all ſorts of domeſtic animals, whether thoſe of the cattle, horſe, and ſwine kinds, or thoſe of the rabbit and poultry deſcriptions. In one of the reports of the ſtate of agriculture, drawn up for the board, it is ſtated that this is a ſubject which "is, perhaps, the moſt important in the whole range of rural economics. The pooreſt and moſt backward nations contrive to raiſe bread for their conſumption, equal to the demand; and to increaſe the quantity with the increaſe of their mouths. Their wheat, in the moſt miſerable huſbandry, is nearly equal, and much of it ſuperior, to that of our highly cultivated fields; and we feel conſtantly in our markets the effect of their competition: but with all that concerns live-ſtock the caſe is abundantly different; it is by great exertions only that a people can be well ſupplied, and for want of ſuch exertions, many nations are forced to content themſelves with ſuch meat as others would not touch. Look at a ſample of French and Swiſs wheat, no difference is found; but examine the cows of Swiſſerland and Lorraine, what a difference! Compare the mares of Flanders with the ponies of Bretagne, the ſheep of England and of France: nay, let us come nearer home, and reflect on the wool in competition; examine the fleeces of Segovia and of Italy, in the ſame parallel of latitude." And it is added that, "next to the cultivation of waſte lands (which by the way much depends on the well ordering of live-ſtock), this, it is conceived, is the greateſt deſideratum in the agriculture of Britain."

And it has been remarked by the author of "Practical Agriculture," that there is ſcarcely any branch of huſbandry that is of more conſequence to the farmer, or which, of late, has been more attended to and improved. He ſuppoſes, indeed, that it might eaſily be imagined that, as the means of ſupporting domeſtic animals became more perfectly known, and more extenſively provided, great and beneficial changes would take place in the nature, form, and other properties of the animals that were to be kept for the purpoſes of the farmer, and conſequently advantages to be derived both in the amelioration of the land and the improvement of the live-ſtock, which it ſupported. It is alſo conceived, that the greatly increaſed demand for this ſort of ſtock, either for the purpoſes of food or labour, may have likewiſe had much effect in promoting and forwarding their improvement; but that, though much has lately been accompliſhed in this department of rural economy, much ſtill remains to be done, which may in ſome meaſure be effected by the judicious combination of proper improved breeds of animals of different kinds, with the various improvements in the cultivation and management of herbage or other ſorts of green food by which they are to be ſupported.

Mr. Middleton likewiſe contends that, where it is intended "to attempt any conſiderable improvement in the nature of the live-ſtock of a farm, care ſhould be previouſly taken that there is a ſufficient degree of ſhelter, ſhade, and warmth, as well as a high degree of fertility of the land, and a ſuitable

able ſtate of drainage, as it is only by the richneſs and abundance of food that ſuch changes can be effected in the moſt advantageous way, or the ſtock be brought to any high degree of perfection." The circumſtances which are to be more particularly conſidered, in undertaking improvements in the nature of live-ſtock, eſpecially in what relates to themſelves, are thoſe of the ſhape, the ſize, the diſpoſition, the hardineſs, the arriving quickly at maturity, the peculiar nature of the fleſh, the property of fattening with expedition, the affording milk in ſufficient plenty, the quality of the hide, the fitneſs for performing labour, and the particular quality or nature of the breed, of whatever ſort of animal it may be. All of which are particularly conſidered in explaining the nature and methods of management that are the moſt proper to be adopted in breeding, rearing, and bringing to perfection different ſorts of animals of the domeſtic kind for the uſes of the farmer. See BREEDING.

In reſpect to the introduction of all ſorts of live-ſtock upon a farm, the cultivator ſhould conſtantly and carefully conſider the nature and extent of his keep, or the means which he has of providing them with proper ſupplies of proper kind of food, as on this, the ſize and other properties of the animals muſt in a great meaſure depend. The idea of good keep is conſtantly neceſſary to be kept in view, as without it, little can be effected in this part of huſbandry. It has been forcibly remarked by the writer of the Staffordſhire Agricultural Report; that "all good ſtock muſt be both bred with attention and well fed; and that it is neceſſary, that theſe two eſſentials in this ſpecies of improvement ſhould always accompany each other; for without good reſources for keeping it would be in vain to attempt ſupporting a capital ſtock, and with ſuch reſources, it would be abſurd not to aim at a breed ſowewhat decent in quality." This ſort of improvement muſt, however, be much regulated by the circumſtances of the farmer, and be often only gradually effected on account of the want of money for the purpoſe of making a more full change in the ſtock of the farm.

In the Agricultural Report for Perth, it is ſtated, that, "there is one circumſtance, relative to the introduction of all new breeds, which muſt not be paſſed over in ſilence, becauſe no farmer can neglect it without a certain loſs. Every kind of paſture is fitted to raiſe animals to a particular ſize. When beaſts of a larger ſize are brought in, than the quality of the food is calculated to ſupport, theſe animals, whether cows, or horſes, or ſheep, or any other kind, will degenerate apace, and never prove uſeful, until they come down to that ſtandard or ſize adapted to their ſituation and ſuited to their food." And that, "on the other hand, when a ſmaller breed than ordinary is brought in, they continue to increaſe in bulk, until they come up to the pitch which is ſuited to their nouriſhment. But there is this remarkable difference betwixt theſe two progreſſions, in reſpect to profit, that in the retrograde progreſs, when animals are brought from rich paſture and a comfortable ſituation to the reverſe, they are in every inſtance worſe than the indigenous breed; whereas the animals, which are brought from worſe to better, continue to improve, till they arrive at that perfection, which the change in their ſituation is calculated to produce. Theſe cauſes may not immediately have their full effect; but in a few years they certainly and evidently will. He makes, for this reaſon, a much ſafer experiment, who brings cattle from worſe to better, than he who brings them from better to worſe. This reaſoning applies to all plants, as well as animals. Highland cattle riſe to a great ſize, not only by the keeping in South Britain, but in rich paſtures at home." And he adds, that it is "in vain to attempt to improve a breed of animals beyond the circumſtances of the country as to climate and paſture; while, at the ſame time, it is no eaſy matter to diſcern, without proper trials, how far theſe circumſtances can ſupport a better ſtock. Here is great room, he ſuppoſes, for the ingenious to exerciſe their judgment in improving the breeds of different animals. One ſpecies has evidently degenerated in this country, by a change in their ſituation to the worſe. The red or foreſt-deer is but a puny animal in compariſon of thoſe of former times. This will be apparent to any perſon, who compares the horns of a deer that is killed at preſent to thoſe of the ſame ſpecies, which are in different places dug out of the moſſes. The cauſe is obvious." It is therefore conceived, that "the improvement of the ſoil ought to go hand in hand with the introduction of a larger breed of cattle: and a large breed ought, for the ſame reaſon, to be introduced, in that degree, in which the ſtyle of agriculture is improved."

In ſupport of this, Mr. Middleton, in the Agricultural Report of Middleſex ſtates, that "the richeſt grazing land, and the moſt nouriſhing artificial food, will certainly pay more in feeding large bullocks, ſheep, and ſwine, than it would do in feeding the ſmaller ſizes of the ſame ſpecies," and that "it is equally obvious that the ſmaller breeds will anſwer better on the poor paſture than the large."

Further, the particular qualities which the farmer has in contemplation, is likewiſe a point which muſt be attended to in fixing upon breeds of domeſtic animals for particular farms. Conſidering the various breeds of domeſtic animals, as the machines by which the farmer is enabled to ſend his herbage and other ſorts of food to market, Mr. Donaldſon thinks he ought, by the ſtudy of every proper mean, to advance their improvement, in reſpect to form as well as the diſpoſition to fatten, that the produce of his farm may be diſpoſed of in the moſt advantageous manner; and that beſides the benefit he would derive individually, from their being thus rendered leſs tedious in the proceſs of fattening, and leſs productive of offal, the community would gain vaſt advantage in the great increaſe of animal food.

As ſoon as proper ſorts of live-ſtock have been introduced according to the particular circumſtances of the land, the farmer ſhould be extremely careful in the management of them, whether they be of the cattle, ſheep, or other kinds, in the providing them with due and full ſupplies of food, whether in the changes of paſture during the ſummer ſeaſon, or in that of other ſorts in the winter, ſo as to keep them conſtantly in a proper thriving condition; in affording them ſuitable degrees of ſhelter and warmth, and in having them properly littered down, when confined to the yards or ſtalls; and under all circumſtances well ſupplied with good water; as all theſe have much effect in promoting the improvement of the ſtock, and, of courſe, that of the advantage of the farmer: different methods are purſued in different diſtricts, with this view, in animals of different kinds, which will be particularly noticed under the heads to which they belong. See CATTLE, SHEEP, HORSE, SWINE, &c.

In many parts of the iſland, great advances have been made to a more perfect ſtate in the nature of different ſorts of live-ſtock, by ſelecting and employing the beſt and moſt perfectly formed animals, both male and female, but eſpecially the former, as ſtock to breed from; and in the midland, as well as ſome other counties, vaſt advantage has been gained in the ſame view, by the practice of the large and more opulent breeders and graziers letting their ſuperior male ſtock of different kinds of animals; and it would probably ſtill further promote this material object, if the more extenſive proprietors of lands were attentive to the circumſtance, by either providing ſuch male ſtock themſelves, or enabling their tenants effectually to do it, where their ſituations render it impoſſible. By ſome well concerted plan of this nature, a great and general change, ſo as to render the different ſorts of domeſtic animals much more perfect than they are at preſent, as well as better adapted to their ſituations, might be effected. But without ſome ſort of aid of this kind it does not ſeem probable, from the great expence attending the buſineſs, that any general improvement of them can take place, though it may be carried to a conſiderable extent in particular caſes and circumſtances.

LIVENSK, in *Geography*, a town of Ruſſia, in the government of Voronez; 36 miles W.S.W. of Voronez. N. lat. 51° 8'. E. long. 38° 14'.

LIVER, in *Anatomy* and *Phyſiology*, is the largeſt gland in the body, and performs the ſecretion of the bile. That fluid is conveyed from the liver by its excretory duct, called the hepatic; which ſometimes tranſmits it to the duodenum, and ſometimes, through a ſecond tube called the cyſtic duct, into the membranous bag connected to the liver, and named the gall-bladder. The anatomical deſcription of theſe organs, and the explanation of their functions are, the objects of this article.

The liver is a ſingle organ, like the others of the organic life, not ſymmetrical in its figure, yet tolerably conſtant in its peculiar ſhape; occupying the upper part of the cavity of the abdomen, where it is placed obliquely from right to left, the thickeſt portion filling up the right hypochondrium, or ſpace included by the falſe ribs of the right ſide, and the thinner part extending acroſs the middle of the body in the epigaſtric region to the left hypochondrium. It is more deeply covered by the ribs in the male than in the female ſex. In general it is ſmaller in proportion as the individual is more healthy: it generally becomes enlarged in ſize when diſeaſed.

It is ſituated immediately under the diaphragm, of which the tendon intervenes between it and the pericardium; and above the ſtomach, arch of the colon, duodenum, little omentum, gall-bladder, and right kidney. Behind, it lies againſt the vertebral column, the crura of the diaphragm, the œſophagus, the aorta and the inferior vena cava: and it is bounded in front by the cartilaginous edge of the cheſt. The right falſe ribs are on its right, and the ſpleen on its left.

The preſſure of the ſurrounding organs juſt enumerated, the connection which the inferior vena cava has to it, but more particularly certain folds of peritoneum, called its ligaments, retain it in its ſituation, leaving it however a conſiderable power of changing its relative poſition. Anatomiſts enumerate four or five ligaments, all of which connect the liver to the ſurface of the diaphragm; but they ſeem to be merely ſo many parts of one and the ſame production. From the middle of the diaphragm, beginning at the apex of the enſiform cartilage, and extending backwards with a little obliquity to the right, and from the aponeuroſis of the tranſverſus abdominis, almoſt as low as the navel, a fold of peritoneum, conſiſting of two laminæ, a right and left, paſſes to the convex ſurface of the liver, and is attached to it from the foſſa umbilicalis to the notch that receives the vena cava. This, which is called the ligamentum latum, or ſuſpenſorium hepatis, is narrow below and in front, grows broader in the middle, where it arrives at the diaphragm, and then becomes again very narrow behind: it poſſeſſes in fact a falciform ſhape, the convex margin being turned upwards, the concave downwards, and the apex backwards. The front and lower edge of the ligament is thick and rounded, and contains the remains of the umbilical vein of the fœtus, ſurrounded by more or leſs fat; this part, which is implanted in the front notch of the liver, is called the ligamentum teres hepatis. The two ſides of the ligament conſiſt of broad and ſmooth ſurfaces; of which one is turned forwards and in contact with the parietes of the abdomen below, and the diaphragm above; the other, turned backwards, lies againſt the liver above and the abdominal viſcera below. Beſides the umbilical vein, the two layers of this ligament include ſeveral lymphatic trunks proceeding from the liver to the cheſt. Its laminæ are continuous on one ſide with the peritoneum lining the abdominal cavity, and on the other with the external peritoneal covering of the liver. Its functions ſeem rather connected with the tranſmiſſion of the umbilical vein than with any confinement of the liver to a particular ſituation: for all the broad anterior portion is ſo looſe, that it does not at all limit the motions of the organ: where it is narrower, it may perform this office. It will confine the liver principally in its lateral motions. It is ſaid to have been ſometimes deficient; but the obſervation appears doubtful.

The two laminæ compoſing the broad ligament ſeparate from each other towards the poſterior part of the organ, and, as they proceed towards the right and left ſides, take the names of right and left or lateral ligaments of the liver. Theſe connect the reſpective lobes to the diaphragm; they have a triangular form; one ſide is looſe, one connected to the liver, and the third to the diaphragm. They conſiſt, like the broad ligament, of two layers of peritoneum, including a ſmall quantity of cellular ſubſtance, and ſome lymphatic veſſels. The left is commonly rather larger than the right.

The coronary ligament of the liver is a broad adheſion between the poſterior part of the organ and the ſurface of the diaphragm: the two parts are united by a cloſe cellular tiſſue through a ſurface of conſiderable extent. The boundaries of this union are formed by a very ſhort reflexion of peritoneum, by the broad ligament in front, and by the lateral ligaments at the ſides. The nature of the connection between the liver and diaphragm, will be beſt underſtood by obſerving the ſurface of the former after it has been removed from its ſituation. We then ſee the two laminæ of the broad ligament ſeparating from each other behind, and departing towards each ſide to form the lateral ligaments, which are alſo connected in a ſtraight line along the back edge of the liver. The broad ſpace, included between all theſe parts, and forming a ſurface of adheſion between the liver and diaphragm, is the coronary ligament. This connection acts very powerfully in maintaining the organ in its proper poſition, and preventing it from moving looſely in the abdomen.

We ſhould alſo enumerate, among the connections of the liver, a portion of peritoneum paſſing from it to the right kidney; and the little omentum which joins it to the ſtomach. (See EPIPLOON.) It muſt be remembered, that the connections juſt enumerated do not ſupport the weight of the liver in the living ſubject, as they appear to do after death, when the abdomen has been laid open. In that caſe the liver ſinks downwards from the diaphragm, becomes ſeparated from it by a conſiderable interval, and is ſupported in a great meaſure by the broad ligament. During life the ſurrounding organs maintain the liver in its place, and theſe are all ſupported and held in their reſpective ſituations by the action of the reſpiratory muſcles. Hence the organ is liable to changes of poſition according as theſe parts are moved, and it may be very variouſly affected in this way, as there are ſo many organs in contact with it. Whenever the diaphragm deſcends, the liver is carried downwards; and it moves in the contrary direction again when this muſcle paſſes towards the cheſt. In the latter ſtate, the thin edge of the liver is completely covered by the margin of the cheſt: hence, when we wiſh to preſs on the liver, we direct the patient to inſpire ſtrongly, that its edge may be thruſt below the ribs. Effuſion into the cheſt drives downwards both the diaphragm and liver: dropſy, pregnancy, or any other ſwellings in the abdomen, puſh them up towards the cheſt. When the ſtomach and inteſtines are empty, the liver deſcends: in the oppoſite ſtate of theſe parts it is puſhed upwards: hence the deſcent of the diaphragm is performed leſs eaſily after a full meal. In any erect poſture of the trunk, the liver deſcends about two finger's breadths, and is higher in about the ſame proportion in the recumbent poſture. When we lie on the right ſide, the liver is ſupported in the concavity of the correſponding falſe ribs, and preſſes on none of the ſurrounding organs; hence we commonly ſleep in that attitude. In lying on the other ſide, the weight of the liver comes upon the ſtomach, which produces unpleaſant feelings after a meal. Beſides theſe changes of poſition, which may happen generally in any ſubjects, there are others of a more peculiar and individual nature, ariſing from different ſize of the organ, greater or leſs concavity of the diaphragm, &c. However the poſition may be altered, the relations to ſurrounding parts are the ſame.

The volume of the organ varies according to age, regimen, and diſeaſe. The former varieties will be conſidered in ſpeaking of its developement. In general, it is the largeſt and heavieſt viſcus in the abdomen. It has been obſerved to be largeſt in thoſe who lead an inactive life, and who indulge in the pleaſures of the table: the ancient epicures uſed to produce an inordinate growth of the liver in geeſe by particular diet and management. But the moſt remarkable variations in the ſize of the liver are thoſe which occur in chronic diſeaſes: ſometimes it is diminiſhed and very manifeſtly indurated; much more frequently it is enlarged, ſometimes ſo much as to weigh ten or twelve or even more pounds. When it increaſes in this way, it uſually takes up a proportionally greater room in the abdomen. Boyer, however, ſaw it weighing eleven pounds, without having paſſed beyond the edge of the cheſt: it had driven the diaphragm upwards, almoſt to the firſt rib, and had reduced the right lung to a very ſmall volume. The ſubject was exceedingly fat. (Traité d'Anatomie, tom. iv. p. 393.) The ordinary weight of the liver in a healthy adult is about three pounds: Soemmerring ſays it may vary from two to five pounds. Its ſpecific gravity is to that of water as 15203 to 10000.

The colour is a browniſh-red, often inclining towards yellow. It is influenced very conſiderably by the quantity of blood in the veſſels, and conſequently is different in different modes of death. The organ is very pale in death from hemorrhage, and of a deep colour in caſes where its venous ſyſtem is much diſtended. Its deviations from the brown-red, which conſtitutes the proper liver colour, are generally into lighter and particularly yellow tints. The edges and inferior ſurface are often quite livid. The colour on the whole is clearer the younger the individual.

The figure of the liver is ſo irregular, that it is not eaſy to deſcribe it with clearneſs: we may ſtate generally that it is thick towards the right and back part, thin towards the left and front, flattened from above downwards, and elongated rather obliquely from the right and below, towards the left and upwards. We diſtinguiſh in it a ſuperior and inferior ſurface, an anterior and a poſterior edge, a right and a left extremity.

The ſuperior or convex ſurface, is convex, and adapted every where to the hollow of the diaphragm, to which it is contiguous throughout, except at the back part, in the ſituation of the coronary ligament, where it adheres firmly to the organ. The convexity is much greater behind and towards the right, than in front and on the left. Its particular direction is ſuch, that on the left it is turned upwards and rather forwards; in the middle upwards and rather more forwards; and on the right, backwards, upwards and outwards. It is divided into two parts, called lobes, by the broad ligament; the right diviſion, which is very much the largeſt, forms the right or great lobe; and the left the left or ſmall lobe.

The inferior or concave ſurface is a little inclined backwards, rather leſs extenſive than the preceding, and ſlightly and unequally concave. It exhibits eminences and depreſſions, ariſing apparently from the relations of the organ to the ſurrounding parts, and deep notches giving paſſage to blood-veſſels, which, as in all important viſcera, are formed in the moſt concealed ſituation about the organ. The following are the objects which this ſurface preſents in ſucceſſion from left to right. In their figure and arrangement they are ſubject to ſuch numerous varieties, that hardly any two livers agree together in this reſpect.

1. A broad ſuperficial depreſſion correſponding to the ſuperior ſurface of the ſtomach, and belonging to the left lobe.

2. The horizontal fiſſure or longitudinal groove (foſſa umbilicalis or longitudinalis, or ſiniſtra) divides all the inferior ſurface from before backwards, from the anterior edge to the left ſide of the paſſage of the inferior vena cava, and thus marks the ſeparation of the right and left lobes on their ſurface. The ſides are ſometimes partially united by a ſmall portion of liver, ſo as to form a canal. Its anterior part lodges the umbilical vein, and the poſterior narrower portion (foſſa ductum venoſi) contains the canalis venoſus, which, like that vein, is changed in the adult into a kind of ligament.

3. The great tranſverſe fiſſure (foſſa tranſverſa, or vena portarum,) is placed nearer to the poſterior than to the anterior edge, and runs from right to left in the direction of the great diameter of the inferior ſurface, of which it occupies about the middle third portion. It interſects the horizontal fiſſure at right angles. Its depth is conſiderable, particularly in the middle, and it is never covered by thoſe tranſverſe bridge-like portions, which have been mentioned in the former fiſſure. It is occupied by the trunk and firſt diviſion of the vena portarum, by the primary ramifications of the hepatic artery, and by the biliary tubes, which unite at their departure from the liver into a ſingle duct. The lymphatics and nerves of the liver are ſeen alſo in this ſituation. Theſe parts are all united by a tolerably cloſe cellular tiſſue.

4. Two eminences, ſometimes called portæ, of which one is placed before and the other behind the middle of the great tranſverſe fiſſure. The former (lobulus quadratus or anonymus) is broad and ſlightly elevated, reſembles a more or leſs regular parallelogram, and varies in ſize, according as the gall-bladder and tranſverſe fiſſure, which bound it, are more or leſs approximated. It extends even to the front edge, and ſeparates the anterior half of the horizontal fiſſure from the gall-bladder. The other eminence has been called the ſmall lobe of the liver, (lobulus Spigelii or papillatus.) It is ſometimes triangular and ſometimes quadrilateral in its figure. It is more prominent than the preceding, and placed at the poſterior edge of the liver, under the trunk of the vena portarum. It is ſingle in this ſituation, and reſts on the vertebræ,

tebræ, between the vena cava and œſophagus; thence it aſcends towards the front on the inferior ſurface of the liver, and is immediately divided into two other ſmall eminences. One of theſe is ſuperior and poſterior (lobulus caudatus), connects the ſmall lobe to the reſt of the liver, and paſſes obliquely towards the right, ſeparating the vena portarum from the vena cava. It then becomes broader, and forms a ſhort ſuperficial groove, continuous with the right extremity of the tranſverſe fiſſure, and on which the vena portarum reſts as it enters that fiſſure. The other eminence is more conſiderable, and forms a kind of obtuſe papilla directed forwards and downwards: this is the part properly called lobulus Spigelii. Separated from the reſt of the liver in front by the tranſverſe fiſſure, behind by the vena cava, on the left by the horizontal fiſſure, and the canalis venoſus contained in it, on the right by the vena portarum before its entrance into the tranſverſe fiſſure, this eminence appears to be connected to the organ only by the kind of root juſt deſcribed, and which paſſes under the right lobes, between the vena cava and vena portarum. But behind it is farther connected by a ſmall elongation, formed ſometimes by the ſubſtance of the liver, ſometimes by a fold of peritoneum, which ſerves to complete a very ſhort canal traverſed by the vena cava. This lobulus Spigelii is placed between the two orifices of the ſtomach: it correſponds below to the pancreas, above to the right and left lobes: in front of it is the little omentum.

5. In the right lobe, in the front of the right extremity of the tranſverſe fiſſure, and on the right of the lobulus quadratus, appears the excavation that lodges the gall-bladder. This is of an oval figore, ſuperficial, more or leſs diſtant from the longitudinal fiſſure, not covered by peritoneum, and lined only by the proper membrane of the liver, and by cellular tiſſue, which connects it ſtrongly to the gall-bladder.

6. Two ſtill more ſuperficial excavations are found quite to the right. The anterior correſponds to the hepatic flexure of the colon, and the poſterior to the right kidney and renal capſule.

The anterior or thin edge of the liver is thin, and inclined downwards. In the natural ſituation of the organ it correſponds nearly to the level of the baſis of the cheſt, being ſometimes a little above, but ſeldom below it. Its direction may be eaſily conceived from the general deſcription we have given of the organ. It is turned almoſt directly downwards on the right, and becomes more directly anterior towards the left. A notch is always ſeen in it towards the left, and forms the commencement of the horizontal fiſſure: to the right of this there is a broader ſuperficial excavation accommodated to the fundus of the gall-bladder.

The poſterior or thick margin is inclined upwards, not ſo long as the anterior, very thick on the right, and grows gradually thinner towards the left. Its middle is cloſely connected to the diaphragm by the coronary ligament; and the extremities are more looſely attached to the ſame organ by the lateral ligaments. Two excavations may be obſerved on this edge: a very deep and narrow one at the poſterior edge of the horizontal fiſſure, between the great lobe and the lobulus Spigelii, for the paſſage of the inferior vena cava; in this the orifices of the hepatic veins are ſeen. It is very ſlightly oblique from the left and below to the right and upwards, and covers about three-fourths of the circumference of the vein, ſometimes indeed the whole of it, forming a complete canal in the ſubſtance of the liver. The ſecond hollow, much broader and more ſuperficial, formed in the left lobe, correſponds to the vertebral column, the aorta, and œſophagus.

The right extremity of the liver is ſituated much lower than the left, and is the moſt bulky part of the organ. The left is very thin, extends more or leſs into the left hypochondrium, reaching above the ſpleen in ſome ſubjects.

Organiſation of the liver.—This is very complicated; beſides its peculiar tiſſue or parenchyma, the nature of which is perhaps more obſcure than that of other glands, it receives a larger number of veſſels. The greater part of the blood, brought from the placenta to the fœtus by the umbilical vein, circulates through this organ; in the adult we find only ſome impervious traces of this veſſel. A peculiar venous ſyſtem, that of the vena portarum, is at all ages entirely diſtributed in the liver. To theſe two orders of veſſels, which are not found in other ſituations, we muſt add the ramifications of the hepatic artery and veins, the nerves, which are ſmall for the organ, the lymphatic veſſels, the excretory tubes, and the peculiar tiſſue incloſed by a double membrane; all of which muſt be ſeparately conſidered.

Of the umbilical venous ſyſtem, which is ſo remarkable in the fœtus, nothing more can be diſcerned in the adult than the fibrous remains of the umbilical vein and canalis venoſus in the horizontal fiſſure of the liver.

The general arrangement and the organiſation of the vena portarum are deſcribed in the article HEART, under the head of *Abdominal ſyſtem of black blood.* We have to add here only a few details belonging to their deſcription.

1. A number of veins varying from three or four to ſeven or eight, of conſiderable ſize, come out of the ſpleen, and run tortuouſly in the fold of peritoneum, which fixes that organ to the ſtomach. After a ſhort courſe, in which they receive branches from the latter, they unite near the pancreas into a ſingle trunk, called the ſplenic vein.

2. The pancreas produces a conſiderable number of ſmall irregular branches, joining indifferently either of the principal trunks of the vena portarum, but more particularly the ſplenic vein.

3. Five orders of venous branches come from the ſtomach, and end either in the trunk or in the large branches, which make up the vena portarum. 1. Several go from the great extremity to the conſtituent branches, or to the trunk of the ſplenic vein. 2. The pyloric vein, belonging to the ſmall curvature, opens into the trunk of the vena portarum. 3. The ſuperior gaſtric or coronary ſtomachic vein, following the artery of the ſame name, joins the ſplenic trunk. 4, 5. The right and left inferior gaſtric veins run along the great curvature, and join reſpectively the trunk of the vena portarum, and the ſplenic vein.

4. The duodenal veins join either the right inferior gaſtric, the ſuperior meſenteric, or vena portarum.

5. The veins of the ſmall inteſtine anaſtomoſe, like the arteries, and form a moſt extenſive net-work between the two laminæ of the meſentery. The communications become fewer and the trunks larger, in proportion as they are more diſtant from the inteſtine: they form at laſt 15 or 20 veins, which join ſucceſſively the large trunk of the ſuperior meſenteric vein accompanying the artery of the ſame name.

6. The veins of the cæcum, right portion of the colon, and right ſide of the arch, follow the courſe of the arteries, and end, under the names of ileo-cæcal, right colic, and middle colic, in the trunk of the ſuperior meſenteric.

7. The veins, which return the blood from the left ſide of the arch of the colon, from the deſcending colon, the ſigmoid flexure and rectum, form as many principal branches as there are chief diviſions of the inferior meſenteric artery: a large trunk, accompanying that artery, is formed by their

union, and is called the inferior meſenteric vein. From the rectum, of which the veins are often called the hæmorrhoidal, the inferior meſenteric trunk aſcends parallel to the inteſtine, goes behind the tranſverſe meſocolon, and terminates behind the pancreas, at a right angle, in the ſplenic vein. This vein is very ſmall at its origin, where it anaſtomoſes with thoſe of the hypogaſtric plexus: it grows larger as it aſcends, and is nearly equal in diameter to the ſuperior meſenteric vein at its termination.

Thus we obſerve, that there are two principal trunks forming the vena portarum, and receiving nearly all the veins of the organs, from which this peculiar venous ſyſtem derives its origin; theſe are the ſuperior meſenteric and the ſplenic; ſome branches, however, directly join the trunk. The ſplenic, formed in the manner already ſpecified, is not tortuous like the artery, runs in company with, but below it, along the upper edge of the pancreas, in an horizontal direction from left to right. In front of the vertebral column it ends, at nearly a right angle, in the vena portarum. In this courſe it receives veins from the great end of the ſtomach, the left inferior gaſtric vein, the inferior meſenteric, the ſuperior gaſtric, and ſeveral pancreatic veins. The ſuperior meſenteric vein, in the greateſt part of its courſe, accompanies the artery of the ſame name, being placed to the right, and a little in front of it. It ariſes where the artery ends, that is, near the cæcum and the right ſide of the colon; it aſcends, following the ſame courſe with the artery, between the two layers of the meſentery, and becomes larger as it receives new branches. At the poſterior edge of the meſocolon it goes behind the pancreas, and joins at a ſomewhat obtuſe angle the ſplenic vein, to form the trunk of the vena portarum, or the ventral or abdominal vena p., as it is ſometimes called, to diſtinguiſh it from that end which ramifies in the liver, and which is called the hepatic vena p. In this ſituation it is more than an inch diſtant from the end of the inferior meſenteric vein. It receives, on the concave ſide of its curve, the three veins from the right portion of the large inteſtine; on the convex or left ſide the numerous veins of the ſmall inteſtine. Several duodenal and pancreatic veins join it where it paſſes between the duodenum and pancreas.

The trunk of the vena portarum, the diameter of which is much leſs than the united diameters of the two preceding veins, goes obliquely upwards to the right, and a little backwards, and paſſes through a ſpace of about four or five inches in the adult, from the vertebral column to the great tranſverſe fiſſure of the liver. At firſt it is ſituated behind the right extremity of the pancreas, and the ſecond portion of the duodenum; it then forms a part of the faſciculus of biliary veſſels contained in the capſula Gliſſoni (ſee EPIPLOÖN), where the biliary ducts and the hepatic artery cover it in front. Like the laſt mentioned parts, it is ſurrounded by numerous nerves, lymphatic veſſels and glands; and theſe organs are all connected by a tolerably denſe and copious cellular tiſſue. When the trunk has arrived at the notch of the liver, it is bifurcated, and each branch forms with it nearly a right angle; ſo that the two taken together repreſent a horizontal canal lying in the notch of the liver, connected cloſely on each ſide to the correſponding diviſions of the hepatic artery, and having the trunk of the vena portarum opening perpendicularly into its middle. This canal, ſometimes called by anatomiſts the ſinus of the vena portarum, does not immediately touch the ſubſtance of the liver; a thick layer of denſe cellular tiſſue ſeparates it, and is continuous with the general external covering of the diviſions of the vein in the organ. The right branch, ſhorter, but much larger than the left, enters the great lobe by the correſponding extremity of the tranſverſe notch, and divides into an uncertain number of branches. The other paſſes horizontally towards the left, as far as the notch containing the umbilical vein, of which the remaining fibrous cord is firmly attached to it, and ſplits into branches diſtributed through the left lobe. The primary and ſecondary diviſions generally purſue a horizontal courſe; they then divide into an infinite number of ramifications, the diſtribution of which we cannot regularly follow, and which end at laſt in a capillary ſyſtem extending throughout the ſubſtance of the organ. Each of the ramifications, which we can eaſily trace in the liver, is accompanied by a branch of the hepatic artery, by one or more biliary ducts, ſome nervous filaments, and lymphatic veſſels. Theſe parts are connected and ſurrounded by a fine layer of cellular tiſſue, which adheres cloſely to the ſubſtance of the liver, and is often deſcribed by the name of capſule of Gliſſon; it ſeems to inſulate the parts which it ſurrounds, as it ſeparates them from the proper tiſſue of the liver. It has no connection with the peritoneum, and the ſuppoſitions of its muſcularity and its propelling the blood by that power are ſupported by no proofs whatever. Boyer regards it as a prolongation of the proper membrane of the liver, which, he ſays, is reflected over all the veſſels that enter or quit the organ. As the parts contained in theſe capſules are connected to each other by looſe cellular tiſſue, which enters the liver with them, the orifices of the vena portarum, on a ſection of the organ, have a looſe plaited appearance, diſtinguiſhing them from thoſe of the hepatic veins, which, as they are intimately connected to the proper tiſſue of the liver, preſerve their circular area, and preſent a much cleaner cut.

The hepatic artery is a branch of the cæliac trunk, and has been deſcribed in the article ARTERY. Its branches enter at the great notch, and every where accompany the ramifications of the vena portarum.

The deſcription of the hepatic veins is given in the article VEIN. We have to notice here only the circumſtances that deſerve attention, concerning their diſtribution in the liver. They return, to the general venous ſyſtem, the blood which is brought into the liver both by the hepatic artery and the vena portarum. They ariſe, therefore, out of the capillary ſyſtem, in which the two orders of veſſels, juſt named, terminate. They unite ſucceſſively into larger and larger branches, which form ultimately three principal and ſome ſmaller trunks, opening into the inferior vena cava, juſt under the diaphragm. This proximity to the heart accounts for their being ſo often diſtended with blood in the dead body. Beſides the direction, in which the blood paſſes through them, the hepatic veins are diſtinguiſhed by two principal circumſtances. Their ſides are rather thinner than thoſe of the vena portarum; and they have no trace of the cellular covering, deſcribed above, as belonging to the ramifications of the latter veſſel, but adhere immediately to the tiſſue of the liver, ſo as to preſent a perfectly circular area on a ſection.

The nerves, which are ſmall in compariſon to the bulk of the organ, come chiefly from the plexus of cæliac ganglia; but ſeveral filaments from the eighth pair join theſe. See NERVE.

The lymphatic veſſels of the liver are very numerous, inſomuch that no other organ ſeems to be more abundantly ſupplied with them. They are diſtinguiſhed into two orders, the ſuperficial and the deep-ſeated. The former cover the whole external ſurface, and are eaſily diſtinguiſhed by the contraſt of their colour with that of the tiſſue of the liver. The latter, ariſing in the ſubſtance of the organ, follow the ramifications of the vena portarum and the hepatic artery. They communicate frequently together, and end by numerous trunks in the thoracic duct, after paſſing through different glands.

The biliary ducts ariſe in all parts of the liver by capillary extremities, which are too minute for our moſt delicate means of reſearch. They unite together, in the manner of veins, into larger and larger trunks, which at laſt end in producing two or three principal ones, quitting the liver at the tranſverſe notch, and then united into a ſingle tube, of about a line and a half in diameter, called the hepatic duct.

All the branches of the hepatic duct in the liver, accompany the diviſions of the vena portarum, and are incloſed with them in the cellular covering already deſcribed. They are eaſily diſtinguiſhed, on a ſection, by the yellow tint which they acquire from the tranſudation of the bile, and the orifices are then called pori biliarii. Indeed, we may eaſily diſtinguiſh, on a cut piece of liver, all the veſſels belonging to it. The yellow colour and greater thickneſs mark the biliary tubes; the coats of the arteries are not quite ſo thick, and not coloured; the branches of the vena portarum are next in order of thickneſs, and are remarkable for their cellular covering; the hepatic veins are the thinneſt.

Whether the capillary beginnings of the biliary ducts come from the acini of the liver, and concur with the capillary blood-veſſels in forming thoſe acini, is a point which we really cannot determine.

Of the peculiar tiſſue or parenchyma of the liver.—The ſubſtance of the organ is next, in point of denſity, to that of the kidney; yet it yields with tolerable facility to the preſſure of the finger.

When we cut into its ſubſtance, we obſerve the colour diſtinguiſhed from that of the exterior by a ſlight yellowiſh tint. It is porous from the great number of veſſels diſtributed through it, and ſeveral yellow points are diſtinguiſhed, which are the ſmall biliary tubes. The different orders of veſſels may be recognized by the characters already explained; the veins contain more or leſs blood, which may be eaſily ſqueezed out. The cut ſurface is ſmooth, and made up of ſmall points alternately of a reddiſh-brown and an obſcure yellow. The ſubſtance of the organ may be eaſily torn; the ſurface is then unequal and granular, compoſed indeed entirely of ſmall granular bodies with every variety of figure, about the ſize of millet ſeeds, of an obſcure red colour, and ſoft conſiſtence. Theſe are the acini of anatomiſts, and are united together, as well as all the veſſels that ramify in the organ, by a fine cellular tiſſue. Long controverſies have exiſted concerning their nature; but we have nothing to add on this ſubject to what we have ſtated in the article Gland.

In fact, we are entirely ignorant of the nature of theſe ſmall bodies, which compoſe the proper tiſſue of the liver, and we know no more concerning its minute organiſation than about that of other parts. We ſee blood-veſſels both of the arterial and venous kind, a peculiar order of veins not found in other organs, lymphatics, excretory tubes, nerves, ſmall ſoft and reddiſh granular bodies, cellular tiſſue to connect all theſe together, and common coverings to inſulate the organ; ſuch is the account of our knowledge concerning the organiſation of this part. Chemiſtry does not diſcloſe to us any thing more ſatisfactory; we know that it is the ſloweſt of all parenchymatous organs in putrefaction, after the kidney; that it loſes much of its weight, and acquires ſomething of a fatty nature by drying; that it is ſoftened by ebullition; diſſolved in ſulphuric acid, which it tinges of a deep violet colour; and rendered coriaceous and greyiſh in nitrous acid. But theſe facts do not much illuſtrate its organiſation. We find, laſtly, that diſeaſe produces in its ſtructure changes as numerous as they are difficult of explanation.

The liver is covered by two membranes, a ſerous and a cellular one, which are very differently arranged.

The external is formed of peritoneum, and covers the whole ſurface, except the poſterior edge, in the ſituation of the coronary ligament, the excavation for the inferior vena cava, that for the gall-bladder, and the two fiſſures of the inferior ſurface. It reſembles the peritoneum in general; is ſmooth and poliſhed on the external ſurface, and connected very cloſely by the internal to the proper membrane of the liver, except in the ſituations already ſpecified.

The other membrane, called by Soemmerring membrana celluloſa hepatis, has been moſt minutely deſcribed by the French anatomiſts, who aſſign the diſcovery of it to M. Laennec. Boyer deſcribes it as covering the external ſurface of the organ, and moreover reflected over the veſſels that enter it. Its internal ſurface correſponds to the tiſſue of the liver, to which it adheres very cloſely. It ſends ſheaths over the veſſels; the moſt conſpicuous of theſe is the capſula Gliſſoni, already deſcribed; but the hepatic veſſels have one cloſely connected to them and to the ſurrounding ſubſtance of the liver, and the umbilical vein in the fœtus is furniſhed with a ſimilar covering. This proper membrane of the liver is thin, tranſparent, and of a ſlightly yellow tint. It is ſtronger than the peritoneum; hardly admits of extenſion, and exhibits nothing fibrous in its texture. It may be beſt ſhewn in the ſituations where it is not covered by peritoneum: by making an inciſion, and introducing the handle of a ſcalpel, it may be eaſily ſeparated from the ſubſtance of the organ.

If the hepatic artery be injected, in a healthy liver, with any fluid kind of injection, as ſize coloured with vermilion, no point can be diſcerned in the whole organ, more particularly if the microſcope be employed, in which branches of this veſſel are not viſible. The ſame obſervation may be made concerning the vena portarum, the hepatic veins, and the hepatic duct. If the injection be puſhed farther, it will paſs out of one of theſe veſſels into the others; that is, it will paſs from the hepatic artery into the vein of the ſame name, into the vena portarum, and into the biliary duct; or, *vice verſâ*, from either of theſe into the artery, &c. Injections do not paſs from the artery into the abſorbents, unleſs when there has been an effuſion into the ſubſtance of the organ. It is ſaid that the abſorbents have been filled with liquors thrown into the vena portarum; and that the ſame circumſtance readily takes place where mercury is introduced into the hepatic duct.

Theſe facts concur with the reſult of the moſt careful inſpection, aided even by the microſcope, in proving that there is an uninterrupted paſſage from one order of veſſels into the other, and nothing of a cellular or veſicular nature interpoſed between them.

Of the apparatus connected with the excretion of the bile.—The tube, which we have already deſcribed, as being formed by the union of all the excretory canals in the liver, under the name of the hepatic duct, paſſes from the great notch of the liver towards the left, being at the ſame time inclined ſlightly downwards and forwards, and is continued to the duodenum, in which it opens. It runs between the two laminæ of the little omentum, ſurrounded by fat and cellular tiſſue, which is generally dyed of a yellow colour by the tranſudation of the bile. It lies on the anterior edge of this omentum, in front and rather to the right of the vena portarum, with which it is extenſively in contact, and to the right of the hepatic artery. Its ſize is about that of a large writing quill, its figure cylindrical, and its length from four to ſix inches. At about an inch or an inch and a half from the liver, we obſerve in it the ſimple round opening of the cyſtic duct. From this part to its termination it generally goes by the name of ductus communis choledochus; but the diſtinction is quite an artificial one. When it arrives near the duodenum, it becomes covered by the pancreas, which adheres cloſely to it, and advances along the poſterior and inferior portion of the ſecond flexure of the duodenum. It penetrates the muſcular coat and that inteſtine, and receives the termination of the pancreatic duct. Having paſſed obliquely between the muſcular and mucous coats, for the ſpace of an inch nearly, it penetrates the latter, and opens into the inteſtine by a ſmall orifice on one of its folds. The mucous coat of the latter, and the internal ſurface of the duct, are here continuous. When we examine the opening of the canal, we ſee a ſmall eminence, nearly of the ſize of a pea, rounded, rather oblong, and divided in the middle; there is no valve, nor any muſcular fibres arranged like a ſphincter. The oblique courſe of the canal between the inteſtinal coats prevents the paſſage of the contents of the inteſtine into the duct, even when the inteſtine is the moſt fully diſtended. The duct is compreſſed whenever the gut is filled, and more powerfully in proportion as the diſtention is greater. If the duodenum be inflated, and the duct cut through, no air eſcapes. Ordinarily, too, we cannot doubt that the particular ſenſibility of the canal enables it to reject matters that are extraneous to it.

Sometimes this duct does not receive the pancreatic. Obſervations are recorded, in which it is ſaid to have opened into the ſtomach, and cloſe to the pylorus; but their correctneſs is doubtful.

The cyſtic duct, of which we have mentioned the opening into the hepatic, is a ſhort canal, leading from the latter tube into the gall-bladder, and conveying into that receptacle a portion of the bile, before it goes to the duodenum.

The gall-bladder.—This bag does not exiſt in ſeveral genera of the mammalia; it has ſometimes, but very rarely, been deficient in the human ſubject, without cauſing any ſenſible derangement of functions. Sometimes alſo there have been two gall-bladders.

It is placed obliquely, under the front of the great lobe of the liver, in the excavation already deſcribed, above the colon and duodenum, to the right of the horizontal fiſſure and the lobulus quadratus, and in front of the right end of the tranſverſe notch. Its moſt uſual figure is pyriform; ſometimes it is rather oval, or cylindrical. We remark in it an external and an internal ſurface, an anterior extremity called the fundus, a poſterior named the neck, and a middle portion or body. The fundus, or large extremity of the gall-bladder, is directed forwards, a little to the right and downwards, and the ſmall end backwards, to the left and upwards. But the direction varies conſiderably according to the attitude of the body. In the ſupine poſture the fundus is higher than the neck; the contrary is the caſe in lying on the right ſide.

The external ſurface of the gall-bladder correſponds above to the excavation in the right lobe of the liver; this part has been called the hepatic ſurface. Here it is not covered by peritoneum, but adheres immediately to the proper membrane of the liver, by means of a copious cellular ſubſtance, containing numerous blood-veſſels. Sometimes it has been connected to the liver by a ſmall kind of meſentery, and covered univerſally by peritoneum. The inferior part is ſmooth, covered by peritoneum, and contiguous to the colon and firſt portion of the duodenum; it is called the looſe or abdominal ſurface.

The anterior extremity, or fundus, turned forwards, downwards and to the right is rounded, ſmooth, and covered partially or entirely by peritoneum. It correſponds to an excavation in the anterior edge of the liver, and protrudes more or leſs beyond this according to the quantity of bile it contains. When it is empty, its fundus does not extend beyond this edge; but, in the diſtended ſtate, it projects from the liver, and is applied againſt the abdominal parietes, below the middle of the cartilage of the ſecond falſe rib.

The neck, or poſterior extremity, which is directed rather upwards and to the left, is bent upon itſelf, the convexity of the curve looking upwards, and the concavity downwards. It is terminated by the cyſtic duct, which, after a courſe of about an inch and a half, unites with the hepatic duct at a very acute angle. The internal ſurface of the gall-bladder preſents a deep yellow or greeniſh tint, according to the colour of the bile; indeed, all this excretory apparatus is tinged after death in the ſame manner, but not ſo deeply as the ſurface of the gall-bladder. This effect takes place very quickly after death: when the coats of the parts, that immediately contain the bile, are coloured, the continuance of the tranſudation affects all the neighbouring organs to a greater or leſs degree. This internal ſurface of the gall-bladder is extremely irregular; it is univerſally covered with riſing lines, decuſſating each other, and intercepting ſmall areolæ of various figures. Theſe are again covered by other more minute lines, which divide the ſurface into very ſmall ſpaces. Similar riſing lines, but more elevated, are found towards the neck of the gall-bladder, and throughout the cyſtic duct. The whole ſurface of theſe parts, in conſequence of this ſtructure, exhibits a very beautiful rugous and cellular appearance. Beſides theſe rugæ of the internal coat, the neck of the gall-bladder exhibits four or five tranſverſe ſemilunar folds, projecting into the cavity, and formed by duplicatures of the mucous coat.

The capacity of the gall-bladder may be eſtimated at about one ounce.

The cyſtic duct is a contracted continuation of the neck of the gall-bladder, about equal to a large crow-quill in diameter. It forms at its commencement a remarkable turn, of which the convexity is towards the liver and the concavity downward. From the gall-bladder it firſt aſcends, then makes this turn, and afterwards paſſes downwards, between the laminæ of the little omentum, parallel and cloſe to the hepatic duct. After a courſe of about an inch and a half it opens into that duct at a very acute angle. The cyſtic duct has an irregular knotted appearance on its external ſurface, which ariſes from numerous ſemilunar folds, analogous to thoſe at the neck of the gall-bladder, projecting into its cavity, and very much narrowing its dimenſions.

Two coats, a ſerous and a mucous, compoſe the gall-bladder. The former, derived from the peritoneum, gives only a partial covering to the organ. This membrane is raiſed from the liver, at the circumference of the depreſſion lodging the gall-bladder, and covers this viſcus every where, except at its adheſion to the ſurface of the liver. It is continuous below with the ſuperior layer of the little omentum. The peritoneal coat is connected to the mucous by a tolerably thick and uniform layer of cellular tiſſue, the cellular coat of ſome writers. Some firm and rather ſhining threads, moſtly of a longitudinal direction, are obſerved in this tiſſue, and have been often conſidered of a muſcular nature. The blood-veſſels and abſorbents form a net-work in this cellular ſubſtance, which ſometimes contains a little fat. The internal, mucous, or villous coat, as it is frequently called, is connected below and at the ſides to the peritoneal covering; above to the proper membrane of the liver. The inner ſurface preſents the rugæ already noticed. It is of conſiderable thickneſs, and has a kind of ſpongy texture. During life it is white; the tint of the bile never being communicated until after death. Several anatomiſts have deſcribed mucous glands and follicles in this membrane; but they cannot be ſatisfactorily aſcertained. Soemmerring, however, deſcribes glands near the neck as large as millet ſeeds. On account of the folds and rugæ of the internal ſurface, its extent is much increaſed when the cellular ſubſtance is removed from the outſide. After a ſucceſsful injection of the blood-veſſels, this coat appears to conſiſt entirely of a vaſcular net-work.

The artery of the gall-bladder is a branch of the hepatic; the veins join the vena portarum. The lymphatics, which are numerous and large, join thoſe of the inferior ſurface of the liver. The nerves come from the hepatic plexus.

Anatomiſts formerly admitted the exiſtence of veſſels paſſing directly from the liver into the gall-bladder, under the name of hepatico-cyſtic ducts. Such veſſels exiſt in birds, but they certainly do not belong to the human ſubject; the only connection between the liver and gall-bladder being through the medium of the hepatic and cyſtic ducts.

The organiſation of the hepatic and cyſtic ducts is eſſentially the ſame. They have two coats, an external fibrous one, and a mucous or internal lining. The former is thick, denſe, and ſtrong, and compoſed apparently of whitiſh longitudinal fibres, which have nothing muſcular in their appearance, and the nature of which is not well underſtood. The mucous coat is thin and ſoft, and preſents in ſome parts the ſame areolated texture as on the internal ſurface of the gall-bladder: the whole of the cyſtic duct has this peculiar arrangement, and its internal membrane forms the tranſverſe folds already mentioned. The hepatic duct, from the liver to near the point at which it enters the inteſtine, is ſmooth: it has ſome longitudinal folds about its middle, and is reticulated near the duodenum.

Theſe ducts poſſeſs very great extenſibility: they are ſometimes dilated, by the paſſage of calculi, to the ſize of a thumb. They, as well as the gall-bladder, act on their contents by the inſenſible organic contractility, or tonic power. They are never ſeen to contract ſenſibly in any obſervations of living animals, nor do the ſtimuli, which excite contractions in the muſcles, produce the ſame effect on them. Probably the paſſage of the food over the orifice of the duct in the duodenum is the exciting cauſe of their actions. Although they are not ſenſible in the natural ſtate, diſeaſe developes this property in them to a remarkable degree. No pain is more acute than that produced by calculi in theſe ducts.

Developement of the liver.—This organ is diſcerned in the embryo before any of the other viſcera; and it is proportionally larger in the early months of conception, than at any future time. Wriſberg ſaw it in a fœtus of ten weeks ſo large, that it occupied nearly the whole abdomen. Walter ſays that it can be ſeen at twenty-two days. At theſe periods it appears to be not much leſs than half the weight of the body. This great bulk of the organ does not laſt through the whole of geſtation; after the fourth month, it does not proceed ſo rapidly in its growth, although it maintains a remarkable predominance over the other viſcera till the time of birth. As a general obſervation we may aſſert, that it is larger in proportion as the animal is nearer to the time of its firſt formation.

During fetal exiſtence, the blood of the umbilical vein circulates through the liver, on its way to the heart: but the whole of this blood is ſent to the left lobe. (See the deſcription of the umbilical veſſels in the article EMBRYO, and the article CIRCULATION.) Hence that lobe is quite as large, if not larger, than the right. From this great bulk of the organ, as well as from the breadth of the baſis of the cheſt, and the ſmall concavity of the diaphragm, the relations of the liver to the ſurrounding parts are very different from what we obſerve in the adult. It not only fills both hypochondria and the epigaſtric region, but deſcends below the ribs, as far as the umbilicus, and fills half the abdomen. It is placed at this time more perpendicularly in the body, ſo that the convex and concave ſurfaces, which are ſuperior and inferior in the adult, are nearly anterior and poſterior in the fœtus. The anterior ſurface is extenſively in contact with the abdominal parietes: the poſterior covers the ſtomach, ſpleen, and even omentum. Its tiſſue at this time is ſoft and ſpongy, and contains a large quantity of blood: the latter circumſtance gives to the organ a darker colour than it has in the adult.

We are entirely ignorant of the functions performed by the liver during fetal exiſtence, of the relation between its ſize and any of the proceſſes of the animal economy, and whether any changes are produced in the blood as it paſſes through the organ.

The excretory part of the hepatic ſyſtem is not proportioned in its developement to the ſize of the liver in the fœtus: for the latter circumſtance is connected with the circulation, and not with the biliary ſecretion. The internal ſurface of the gall-bladder is at firſt ſmooth, and does not exhibit the areolated ſtructure until the latter months of geſtation. According to different authors this bag contains no bile, but merely a reddiſh mucus, until the 4th, 5th, or 6th month: its fundus is completely concealed behind the edge of the liver. At the time of birth it is always full of bile; but the fluid is ſtill reddiſh and mucous, and poſſeſſes but little taſte.

The ſudden revolution that occurs in the circulating ſyſtem at birth, produces a remarkable change in the liver. The interception of the blood, which was conveyed to the organ by the umbilical vein, is followed by a very marked reduction in its ſize affecting particularly the left lobe. The tiſſue of the organ is rendered more denſe, and its colour acquires a brighter red tint, or becomes pale. After a certain time the organ participates in the progreſs of the other parts of the body. The excretory apparatus undergoes no remarkable change: it is not ſo readily tinged with bile, as at a more advanced age, probably from ſome change in the nature and properties of that fluid. In the old ſubject the organ ſometimes is reduced in ſize, and frequently becomes more ſoft. On the whole, however, after the changes conſequent on birth have been completely effected, and the liver has acquired its permanent relation to the other organs, very little change takes place in it.

The ſecretion and courſe of the bile.—That this fluid is ſeparated in the liver, and conveyed from that organ by the hepatic duct, are points ſo clear, that they do not require any expreſs proof. From which order of veſſels in the liver this ſecretion takes place, is a queſtion not ſo eaſily anſwered. Phyſiologiſts have generally aſcribed this office to the vena portarum, and have conſidered the hepatic artery to be the nutrient veſſel of the organ, as the bronchial arteries are of the lungs. They give the following reaſons for this opinion. 1. The excretory duct is larger than the artery, a circumſtance which does not occur in any other gland: its ſize however

ever is ſuitable to that of the vena portarum. 2. The agreement of the properties of the bile, particularly its thick oily nature, acrid taſte, and dark colour, with the ſuppoſed peculiar nature of the blood returned by the vena portarum. This blood, it is ſaid, is brought from very warm and moiſt parts, loaded with fatty matter from the omenta meſentery, &c. and with alkaline and acrimonious particles from the inteſtines, particularly the large ones. Its ſuppoſed ſtagnation in the cells of the ſpleen has been conceived to impart to it ſome further peculiar properties, favourable to the formation of the bile. 3. Experiments on living animals, in which the ſecretion has been ſtopped by tying the vena portarum, and not interrupted by tying the hepatic artery. 4. The peculiar diſtribution of the vein, after the manner of an artery, in the liver, combined with the particular qualities of the blood circulating in it. 5. The artery is larger in ſize in the fœtus, in proportion to the greater bulk of the organ, although the ſecretion of bile is very ſmall in quantity at a time when digeſtion has not begun.

As a proof that bile may be ſecreted from arterial blood a fact may be adduced, that occurred to Mr. Abernethy, and is recorded in the Philoſophical Tranſactions. In a well-formed and nouriſhed child, whoſe gall-bladder contained bile, the vena portarum terminated in the inferior vena cava near the renal veins.

There are ſeveral other conſiderations tending to weaken our confidence in the received opinion. Much reliance cannot be placed on the relative diameters of the artery and duct: if the latter be too large for the former, it muſt be regarded as too ſmall in proportion to the vena portarum. According to Bichat there is the ſame relation between them as between the renal artery and ureter.

We know of no comparative analyſis of the blood, contained in the vena portarum and the hepatic artery, that warrants us in aſcribing to the former qualities particularly ſuited to the ſecretion of bile. Certainly we do not ſee in it thoſe properties which are ſaid to characteriſe it: we do not diſcover oily particles in it, and we believe the ſuppoſition of its imbibing any thing from the excrement to be perfectly gratuitous. Indeed Haller expreſsly acknowledges that the properties, which the blood of the vena portarum *muſt* neceſſarily acquire in its circulation, cannot be diſcovered by chemical analyſis. Why is venous blood ſo particularly ſuited to the ſecretion of an oily fluid? are not fat, the medulla of bones, and cerumen formed from materials conveyed in the arteries? That any thing acquired by the blood in the ſpleen cannot be eſſential, is proved by the fact, that extirpation of that organ does not injure the hepatic functions. We do not underſtand clearly how the retarded motion of the blood in this vein (if in reality it be retarded) aſſiſts the formation of bile? How happens it that ſlowneſs of motion is more favourable to this than to any other ſecretion? We cannot reaſonably apply inferences drawn from what takes place in an animal after ſuch a ſerious injury as the ligature of the vena portarum or hepatic artery, to the natural functions of the organ. How long did the animals live after theſe experiments? and in what way were the facts of the ſecretion or non-ſecretion of the bile aſcertained? "Theſe different reflections," ſays Bichat, "may convince us, that our proofs are not as yet ſufficient to decide whether the bile is ſecreted from arterial or from the abdominal ſyſtem of venous blood. I do not attribute the function to one rather than to the other: but merely endeavour to ſhew that a freſh examination of the queſtion is neceſſary, and to prove by this example that the moſt generally received phyſiological opinions, ſuch as ſeem to be placed beyond all doubt by the concurring aſſent of the moſt celebrated men, often reſt on very uncertain foundations. We are yet far from the time when this ſcience ſhall conſiſt only of a ſeries of facts rigorouſly deduced one from the other." Anatomie Generale, tom. i. p. 457.

The great ſize of the liver, the number and magnitude of the parts which compoſe its complicated vaſcular machinery, its enormous magnitude in the early ſtages of fetal exiſtence, and its eſpecial connection with the circulating organs at that period, all lead us to conclude that it anſwers ſome other purpoſe in the economy beſides the ſecretion of the bile. This probability, and the reaſons on which it is grounded, are ſo well ſtated by Bichat, in his Anatomie Generale, that we ſhall avail ourſelves of his labours on this point.

"From ſerving as the point of termination for the abdominal ſyſtem of black blood, as the lungs do for the general ſyſtem of the ſame deſcription, the liver derives a degree of importance, which does not belong to any other ſecretory organ. The diſproportion between the ſize of the organ and the quantity of fluid it ſecretes, has led ſome authors to ſuſpect that the organ muſt have a further office: and this ſuſpicion ſeems to be almoſt a certainty. Compare its excretory tubes and reſervoir to the analogous parts in the kidnies, the ſalivary glands, the pancreas: you will find them inferior to the firſt, and hardly ſuperior in ſize to the others. Yet the maſs of the liver at leaſt equals all the other glands in the body put together. This great ſize of the organ contraſts remarkably with the ſmall quantity of its ſecretion: calculate how much is conſumed in colouring the feces, open the inteſtines to ſee how much they contain at different times, and you will be convinced that the quantity of the bile is much leſs than that of the urine, not to mention the other ſecreted fluids, ſuch as the ſaliva, pancreatic liquor, ſemen, mucous fluids, &c.

"We are altogether ignorant what the other uſe of the bile may be. Probably it is connected with the abdominal ſyſtem of black blood. The following conſiderations prove that it muſt be a very important one. The organ exiſts in almoſt all claſſes of animals, even where ſome other important viſcera are very imperfect. Many of the paſſions affect it: ſome of them have an excluſive effect on it. It performs in diſeaſe as prominent a part as any of the important viſcera of the economy. In hypochondria, melancholia, &c. its influence is very conſiderable. We know how eaſily its functions are diſturbed. If it be unconnected with many affections called bilious, and which have their ſeat in the ſtomach, it is certainly eſſentially concerned in the greater part. The yellowiſh tint of the face in many of theſe affections muſt be produced by the ſame cauſe, which, in a higher degree, produces jaundice. The affections of this organ, obſerved after death, are more numerous than thoſe of any ſimilar part. It is a matter of common obſervation, that this organ has a great influence on the temperament. Its predominance communicates to the external habit of the body, to the functions, to the paſſions, even to the character, a peculiar tint, which was obſerved by the ancients, and the reality of which has been confirmed by modern obſervation. Nothing like this can be obſerved of the other glands. With the heart and brain this is the part firſt formed: its developement precedes that of all other organs, and is incomparably ſuperior to that of other glands. It has been latterly ſuppoſed that the liver aſſiſts the lungs in removing from the blood hydrogen and carbon. I know not on what proofs this aſſertion may reſt: but the colour of the fluid is certainly not affected by its paſſage through the liver: neither is it altered in conſiſtence, nor in any way that can be recognized by the touch."

Courſe of the bile.—There are two kinds of this fluid, differing conſiderably in their properties, and diſtinguiſhed by the names of hepatic and cyſtic. The former, which is contained in the hepatic duct, and in the branches of that tube diſtributed through the liver, approaches in fluidity to water, is of a bright orange colour, and not bitter: ſo far, indeed, is it from containing any qualities offenſive to the taſte, that the livers of animals, which muſt always contain much of it, are commonly employed for food. The latter, or bile of the gall-bladder, is a thick ropy fluid, of a deep orange, brown, or even green tint, and moſt intenſely bitter. Both theſe kinds are ſecreted in the liver, and originally are not different. The gall-bladder receives what it contains through the cyſtic duct, and produces in it the changes juſt deſcribed while it remains in this reſervoir. A copious mucous ſecretion takes place from its lining, and the aqueous parts of the bile are removed by the numerous and large abſorbents of the receptacle. The cyſtic bile is, therefore, nothing more than hepatic bile in a concentrated ſtate. It is eaſy to prove that the gall-bladder can receive bile only through the cyſtic duct: we have already obſerved, that the hepatico-cyſtic ducts are imaginary; we may add, that if the bladder be removed with its contents, the cyſtic duct tied, and preſſure then applied to the part in every direction, not a particle of the fluid eſcapes. If the cyſtic duct be obſtructed by a calculus, or obliterated by diſeaſe, no bile is contained in the gall-bladder, which, on the contrary, is filled with a colourleſs mucus. If we evacuate the receptacle in a living animal, and tie its duct, it will be found under the ſame circumſtances; and the cyſtic duct, from its opening into the hepatic to the ligature, will be diſtended.

The gall-bladder, from the view of its functions, does not ſeem to be a very important organ in the economy. Several animals, among the mammalia, do not poſſeſs it, as the horſe, ſtag, elephant. No ill effects have been obſerved, where the cyſtic duct has been obliterated; nor where there has been a natural deficiency of the organ.

That the fluid ſecreted in the liver flows in part directly into the inteſtine, would be naturally inferred from obſerving the ſize and favourable direction of the hepatic duct for this courſe, and the comparatively unfavourable direction, tortuous courſe, and ſmall diameter of the paſſage leading into the gall-bladder. Theſe circumſtances, indeed, would lead us to expect that the bile would enter the gall-bladder in very ſparing quantity. If an animal be opened, when the inteſtinal functions are not going on, the hepatic duct, and the ductus choledochus, contain hepatic bile; the ſurface of the duodenum and jejunum is tinged with the ſame kind of fluid; and the gall-bladder is diſtended with cyſtic bile, of which the properties are the more ſtrongly marked in proportion to the length of the previous abſtinence. While the ſtomach is exerting its action on the food, the ſame appearances are exhibited. When the aliment has paſſed into the duodenum, the ductus choledochus contains dark-coloured cyſtic bile, and the gall-bladder is leſs full. At the end of digeſtion, and a little after, the hepatic and common ducts, and the gall-bladder, all contain a light-coloured bile; which is obſerved alſo in the duodenum. The gall-bladder is flaccid. Theſe obſervations are deduced from experiments made by Bichat, and recorded in his Anatomie Generale, p. 459. "They were repeated," ſays he, "a great number of times, and ſhew clearly, that the ſecretion goes on to a certain amount at all times, but that this quantity is increaſed during digeſtion. The bile furniſhed when the action of the inteſtine is not going on, is divided between the inteſtine, which is always coloured by it, and the gall-bladder, which retains it without pouring out any through the cyſtic duct: while it is thus retained, it acquires its acrid character, deep tint, and the properties which ſeem to be required for the purpoſes of the digeſtion that is to enſue. When the food, after undergoing the action of the ſtomach, enters the duodenum, all the hepatic bile flows into the inteſtine, and even in greater quantity than before. The gall-bladder at the ſame time pours out its contents. When the action of the inteſtine is concluded, the quantity of fluid ſecreted by the liver is diminiſhed, and it flows partly into the duodenum, and partly into the gall-bladder, where it is then ſeen in ſmall quantity, and of a bright colour, becauſe there has not yet been ſufficient time for it to be collected more abundantly, nor to acquire a deeper colour." Bichat is of opinion that the ſtomach always contains a certain quantity of bile. "In its empty ſtate," ſays he, "we always find in it more or leſs mucous fluid, ſometimes mixed with ſmall globules of hydrogen gas, and almoſt always tinged of a yellowiſh colour by bile, which has entered through the pylorus. Haller ſays, that this reflux does not always take place; but it is conſtant, according to Morgagni. I have opened no dog where it could not be manifeſtly diſcerned in the empty ſtomach, particularly when it had been long empty. The bodies of perſons, who die of diſeaſe, are not fit for deciding this queſtion, as the diſeaſe may alter the courſe, nature, and colour of the bile. When the ſtomach was full, I could not ſometimes aſcertain the preſence of bile: in other inſtances I obſerved a yellowiſh fluid between the alimentary maſs and the coats of the ſtomach. The bile entering the ſtomach has always appeared to me, from its colour, to be hepatic; I have never ſeen that dark fluid which is contained in the gall-bladder, and which is vomited in ſome diſeaſes. This accords with the obſervation made above, that hepatic bile only enters the duodenum during abſtinence. It is evident that the paſſage of the food from the ſtomach, at the commencement of inteſtinal digeſtion, at which time cyſtic bile certainly flows into the duodenum, muſt prevent that bile from going through the pylorus."

We have mentioned, in the article DIGESTION, the effects produced on the contents of the inteſtine by the admixture of the biliary fluid. On this ſubject, indeed, the amount of our knowledge is very trifling: that the preſence of the fluid is eſſential to the right performance of the inteſtinal functions, and that the colour of the fæces is derived from its admixture, are obvious facts, and they include nearly all that is hitherto proved.

The chemical compoſition of the fluid is conſidered under the article BILE.

The ſympathies of the liver, with other organs, are very numerous and important; and render its phyſiology very intereſting to the phyſician. It is connected primarily or ſecondarily, as cauſe or effect, with various diſorders of the head, cheſt, and abdomen.

LIVER, *Chronic diſeaſes of the*, in *Medicine*.—Having already treated of the *acute* inflammatory affections of the liver (ſee HEPATITIS), and of the various obſtructions to the exit of the bile into the inteſtines, which give riſe to *Jaundice* (ſee that article); it remains for us to deſcribe, in this place, the other morbid changes to which this organ is liable, and which are of a ſlow or *chronic* kind. Theſe are, principally, the ſlow inflammation of the liver, or chronic hepatitis, as it has been called; induration, or a ſcirrhous ſtate of the organ; ſoftneſs of it; enlargement, or diminution of its bulk; the formation of tubercles in it; adheſions of it to the contiguous parts, &c. The formation of thoſe veſicular cyſts, which are denominated *hydatids*, in the liver, has been already diſcuſſed under the general head. See HYDATIDS.

The chronic inflammation of the liver is a diſeaſe, which is more common in this country than the acute; and is often ſo inſidious in its progreſs, and accompanied by ſo few ſymptoms of ſerious indiſpoſition, as to have advanced to a complete ſuppuration, before its exiſtence was ſuſpected. In ſome meaſure, indeed, a ſimilar obſervation applies to all the chronic derangements of the ſubſtance of the liver, which often excite no alarm, by the ſymptoms which might be expected to accompany them, until they are fully formed. The ſlight indiſpoſition that occurs is attributed to indigeſtion, flatulence, or ſome other affection of the ſtomach; the pain of which the patient occaſionally complains is falſely referred to that organ; and its continuance is ſo ſhort, and the degree of it frequently ſo inconſiderable, as to demand but a ſlight attention. The relief obtained by eructation and the diſcharge of air alſo tends to confirm the opinion, that the ſeat of the diſeaſe is in the ſtomach: but this relief may be explained on the principle of removing the diſtention of the ſtomach, and ſo taking off the preſſure of this organ from the liver.

Where this ſlow inflammation and gradual obſtruction is going on in the liver, the patient is ſubject to occaſional pain in the right hypochondrium, extending to the *ſcapulæ*, or to the top of the ſhoulder, a quick pulſe, an increaſe of heat, alternating with chilly ſenſations, difficult breathing on quick motion, ſome difficulty of lying on the left ſide, flatulence, indigeſtion, acidity, coſtiveneſs; and, together with a gradual diminution of ſtrength and fleſh, he has a pale or ſallow complexion. The complexion, indeed, of a perſon affected with chronic obſtruction in the liver, although often not wearing the appearance of jaundice, yet has frequently a peculiar ſallowneſs, or a dirty-greeniſh hue, which Dr. Darwin, from its reſemblance to the colour of a full-grown ſilk-worm, has aptly enough denominated *bombycinous*. The extent and duration of pains, Dr. Saunders obſerves, ariſing from diſeaſe of the liver, are ſo various, as frequently to deceive both the phyſician and patient; they extend to the ſhoulder, ſcapulæ, muſcles of the neck, along the arm, even to the joints of the wriſt. Every change of poſture either relieves an old pain, or induces a new one, as does the mere bending of the body in any direction, or even extending the arms. The pains are greater in a ſupine, than in an erect poſture.

Theſe ſymptoms, and ſome others which make their appearance in the more advanced ſtages, are ſufficient to point out the exiſtence of chronic diſeaſe in the liver: but it is to be regretted, that they are not peculiar to chronic inflammation of the organ; and that the varieties of hepatic obſtruction are not diſtinguiſhed from each other by any particular combinations of ſymptoms; for it muſt be obvious, that the ſame remedies cannot be adminiſtered with advantage in diſeaſes, which are eſſentially ſo different in their nature, as thoſe which we are about to deſcribe.

The term *ſchirrus*, when applied to the liver, has been employed in two acceptations, or at leaſt to denote two different ſtages of a diſeaſe, if not two different diſeaſes: namely, an induration of the ſubſtance of the liver generally, and the formation of the common tubercle in it; the former of which is, in the opinion of Dr. Baillie, the firſt ſtep towards the latter. When an indurated liver is examined by diſſection, no peculiar alteration of ſtructure is obſerved; only the ſubſtance of the gland is found uniformly of a more compact and ſolid conſiſtence, or leſs ſoft and porous, it is ſomewhat diminiſhed in bulk, and the lower edge is bent a little inwards; the colour, too, is ſomewhat paler, in conſequence of a diminiſhed ſecretion of the bile, or of a leſs free admiſſion of blood into the ſubſtance of the organ. Upon the ſurface of ſuch a liver, Dr. Baillie remarks, "there is not uncommonly a thready appearance of membrane, diſpoſed ſomewhat in a radiated form. This, I believe to be the firſt ſtep in the progreſs towards the formation of the common tuberculated liver. I have ſometimes ſeen ſmall tubercles formed upon a part of the ſurface of ſuch a liver, which were exactly of the common ſort, &c. This hardened ſtate of the liver is ſometimes accompanied with a beginning aſcites, and ſometimes is without it." Loc. cit.

Dr. Saunders obſerves, that in theſe caſes of induration of the liver, there is, together with a diminution of bulk, alſo ſome degree of loſs of weight. This, however, he believes, occurs only in the latter ſtages of the diſeaſe, when it is uſually ſeen by the anatomiſt. For, conſidering that the diſeaſe is commonly the reſult of one of the two following cauſes, *viz.* a long reſidence in a hot climate, or the immoderate uſe of ſpirituous liquors, both of which tend to produce an over-excitement of the circulation, and a hurried ſecretion, he deems it moſt probable, nay he is perſuaded, that in the more early ſtages of ſchirroſity, the liver is not only not ſenſibly diminiſhed in bulk, but that there is at that period an increaſe both of bulk and weight, which is followed by a gradual diminution of both. "To produce an increaſed ſecretion of bile," he argues, "it is plain that there muſt be an increaſed action of the branches of the vena portarum, and an acceleration of fluids through thoſe branches: hence a condition of veſſels is induced, approaching in ſome reſpects to that of inflammation; with this difference, that it is an inflammation in which the vein, or ſecreting veſſel, is more concerned, than the artery or nutrient veſſel. The effect of this action, eſpecially when protracted for a conſiderable time, muſt neceſſarily be that of inducing an alteration in the ſtructure of the part; an alteration ſimilar to what obtains in other organs, labouring under indolent and chronic inflammation. This change of ſtructure, from its ſolidity and compactneſs, ſeems to depend on the effuſion of the coagulable lymph into the parenchymatous ſubſtance of the liver; with this peculiarity, that while it is, in active inflammations, depoſited by arteries, it is, in the chronic kind, effuſed by the veins, &c." This effuſion, however, he adds, impedes the ſecretion of bile; and, where a part has loſt the power of performing its functions, the abſorbents often become active, and remove it: whence the diminution of weight as the diſeaſe advances. (Saunders's Treatiſe on Structure and Diſ. of the Liver, 3d edit. p. 282, et ſeq.) At all events, the view of the diſeaſe, which aſcribes the effuſion of the interſticial matter, and the conſequent induration, to a previous excitement of the veſſels and hurried ſecretion, accord both with the general laws of the animal economy, and with the known ordinary cauſes of this diſeaſe.

With reſpect to the other modification of ſchirrous liver; which is one of the moſt common of its diſeaſes, we cannot do better than repeat Dr. Baillie's accurate deſcription. "This diſeaſe," he ſays, "is hardly ever met with in a very young perſon, but frequently takes place in perſons of middle or advanced age: it is likewiſe more common in men than in women. This ſeems to depend upon the habit of drinking being more common in the one ſex than in the other; for this diſeaſe is moſt frequently found in hard drinkers, although we cannot ſee any neceſſary connection between that mode of life and this particular diſeaſe in the liver. It happens, however, very commonly, that we can ſee little connection between cauſe and effect in changes which are going on in every other part of the body.

"The tubercles, which are formed in this diſeaſe, occupy generally the whole maſs of the liver, are placed very near each other, and are of a rounded ſhape. They give an appearance every where of irregularity to its ſurface. When cut into, they are found to conſiſt of a browniſh or yellowiſh-white ſolid matter. They are ſometimes of a very ſmall ſize, ſo as not to be larger than the heads of large pins; but moſt frequently they are as large as ſmall hazel nuts, and many of them are ſometimes larger. When the liver is thus tuberculated, it feels much harder to the touch than natural, and not uncommonly its lower edge is bent a little forwards. Its ſize, however, is generally not larger than in a healthy ſtate, and I think it is often ſmaller. If a ſection of the liver be made in this ſtate, its veſſels ſeem to have a ſmaller diameter than they have naturally. It very frequently happens that in this ſtate the liver is of a yellow colour, ariſing from the bile accumulated in its ſubſtance; and there is alſo water in the cavity of the abdomen, which is yellow, from the mixture of bile. The gall-bladder is generally much contracted, and of a white colour, from its being empty. The bile, from the preſſure of the hard liver upon the *pori biliarii*, does not reach the *ductus hepaticus*, and therefore cannot paſs into the gall-bladder. The colour of the ſkin in ſuch caſes is jaundiced, and it remains permanently ſo, as it depends on a ſtate of liver not liable to change. This is the common appearance of what is generally called a ſchirrous liver: but it bears only a remote reſemblance to *ſchirrus*, as it ſhews itſelf in other parts of the body. I ſhould therefore be diſpoſed to conſider it as a peculiar diſeaſe affecting this *viſcus*." Morbid Anat. chap. ix.

This account of the ſtate of the indurated and tuberculated liver renders it unneceſſary to explain, at any length, the origin of the dropſy, jaundice, &c. which accompany theſe diſeaſes, when inveterate. It muſt be obvious to thoſe who underſtand the ſtructure of the parts, that if ſome bile is ſecreted in the liver, but, from the compreſſed ſtate of the ducts, it cannot paſs into the inteſtines, it will be abſorbed into the circulating blood, and produce jaundice. (See Jaundice.) And dropſy will enſue, in conſequence of the impermeability of many of the blood-veſſels of the liver, which are compreſſed by the ſurrounding tubercles; whence, as in all caſes of ſuch obſtruction to the circulation, the thinner parts of the blood will exude from the exhalant extremities of the over-diſtended veſſels behind. (See Dropsy, *cauſes of*.) From the ſame obſtruction, and the over-diſtention of the venous ſyſtem, theſe veſſels are liable to give way; whence hemorrhagies, or diſcharges of dark blood, are liable to occur, under ſuch morbid ſtates of the liver, from the ſtomach, inteſtines, noſe, and other internal paſſages; but eſpecially from the two former, ſince the blood which circulates through them, as well as through the *ſpleen*, *pancreas*, and *omentum*, muſt paſs through the liver to reach the heart; the circulation, therefore, muſt be particularly impeded in the organs juſt mentioned, when that of the liver is obſtructed; and the blood will force its way through other paſſages, if the veſſels are not ſtrong enough to reſiſt any extraordinary diſtending force.

The liver is liable to be affected with other varieties of tubercle, of a larger ſize than thoſe above deſcribed: Dr. Baillie has mentioned three varieties of theſe, which he calls the large white tubercle, ſoft brown tubercle, and ſcrofulous tubercle. The firſt of theſe, which is by no means ſo frequently met with as the common tubercle, reſembles more nearly the ordinary appearance of ſchirrus in other parts of the body. Theſe tubercles are hard whitiſh maſſes, of a globular form, and firm opaque ſubſtance, often as large as a cheſnut, and ſometimes much larger, or on the other hand, conſiderably ſmaller. "They are to be found near the ſurface of the liver," Dr. Baillie obſerves, "in greater number, than near the middle of its ſubſtance: two or three frequently lie contiguous to each other, with a conſiderable portion of the liver, in a healthy ſtate, interpoſed between them and a cluſter of ſimilar tubercles. The liver in this diſeaſe is frequently a good deal enlarged beyond its natural ſize." Dr. Baillie adds, that "theſe tubercles appear to be firſt formed round the blood-veſſels of the liver, as is ſeen in making ſections of a liver in this ſtate. While the liver is under ſuch circumſtances of diſeaſe, there is ſometimes water in the cavity of the abdomen, and ſometimes none; the liver is ſometimes tinged in its colour, from the accumulation of bile, and ſometimes the colour of its ſubſtance, between the tubercles, is perfectly natural." (Loc. cit.) The two other ſpecies of tubercle are very rare; the one conſiſts of a ſmooth, ſoft, browniſh matter, the nature of which is not thoroughly known; the other bears a ſtrong reſemblance to the tubercle of the lungs. See Consumption.

There are no peculiar ſymptoms, by which the exiſtence of theſe different tubercles can be diſcriminated in the living body. When the parietes of the abdomen are thin, and there is little dropſy, and eſpecially when the liver is enlarged, the tubercles can ſometimes be diſtinctly felt by the fingers, upon an attentive examination, along the lower edge of the viſcus. Dr. Baillie correctly ſtates, that the large white tubercle is not ſo often attended with jaundice and aſcites as the common tubercle. We witneſſed the exemplification of theſe obſervations, in a ſtriking inſtance, ſome years ago; in which a woman, addicted to ſpirit-drinking, had been affected with the large tubercle of the liver for ſeveral years, but had complained only of loſs of appetite, and occaſional ſickneſs and pains in the ſide, had been pregnant and brought forth twins, and never had any appearance of dropſy to the laſt, nor of a jaundiced complexion, until within eight days of her death. Yet in this perſon, the liver was not only found about three times its natural bulk, (filling half the cavity of the belly, and being diſtinctly felt, before death, extending down the *umbilicus*, and thence to the ſpine of the *pelvis*,) but appeared, on making a ſection, to conſiſt of a mere maſs of tubercles, with ſome looſe interſticial matter, but without any ſemblance of the natural ſubſtance of the viſcus. The ſection preſented an appearance not unlike the pudding-ſtone of mineralogiſts. It would ſeem that, from the laxity of the intervening ſubſtance between the tubercles, the circulation through the branches of the *vena portæ* was not materially impeded; and hence no dropſical effuſion took place from the veſſels of the peritoneal viſcera. The patient was confined to bed only eight days, and was apparently cut off by an inceſſant agoniſing pain in the diſeaſed organ, which firſt induced delirium, and afterwards wore out the powers of life.

The liver is not unuſually found ſofter and much more flaccid in its ſubſtance than natural, without any other appearance of diſeaſe. It feels, in ſuch inſtances, nearly as ſoft as the ſpleen, and is commonly of a leaden colour. This ſtate of liver is ſeldom, if ever, found in young perſons; moſt commonly in perſons advanced in life. Some other rare morbid changes have alſo been ſeen in the liver; ſuch as the converſion of part of its coats into cartilage, and the formation of cartilaginous cyſts in its ſubſtance, containing an earthy matter of a ſoft ſmooth quality, and browniſh-white colour.

It is not unuſual, on diſſection, to ſee adheſions formed between the liver and the contiguous parts, which are the conſequence of a previous inflammation in the membrane covering the liver. Theſe adheſions are formed from the coagulable lymph of the blood, which undergoes a gradual proceſs of elongation from the motion of the parts, ſo as to produce little inconvenience, and in ſome circumſtances of diſeaſe much advantage. They conſiſt very commonly of a thin tranſparent membrane, which joins the ſurface of the liver to the neighbouring parts. This junction may either be general over one extended ſurface of the liver, or it may conſiſt of a number of proceſſes of adheſion: the adheſion is ſometimes by a membrane of conſiderable length; and ſometimes it is very cloſe, the ſurface of the liver being immediately applied to the neighbouring parts. Theſe adheſions are moſt commonly found on the anterior ſurface of the liver, by which it is joined to the *peritonæum* lining the muſcles at the upper part of the cavity of the abdomen. When an abſceſs is formed in the ſubſtance of the liver, and points externally, theſe adheſions are of great uſe in preventing the *pus* from eſcaping into the general cavity of the abdomen. Adheſions are alſo frequently found connecting the poſterior ſurface of the liver to the ſtomach and the *duodenum:* and theſe may alſo be uſeful in abſceſſes of the liver, near its poſterior ſurface, by preventing the matter from paſſing into the general cavity of the abdomen, and conducting it either into the ſtomach, or the upper part of the inteſtinal canal. See HEPATITIS.

Profeſſor Portal of Paris, an able and ſedulous cultivator of morbid anatomy and medicine, has pointed out ſome difficulties in forming an accurate diagnoſis, between diſeaſes of the liver and of ſome of the neighbouring organs, eſpecially of the lungs. On the one hand, he obſerves, that obſtructions and congeſtions in the right lobe of the lungs, and the right cavity of the cheſt, ſometimes occaſion ſuch an alteration in the ſituation of the liver, by preſſing down the diaphragm, as to produce a ſuſpicion of diſeaſe in it, by occaſioning the appearance of a tumour in the right hypochondrium. He relates a caſe of this ſort, in which he was deceived, by this apparent tumour, in a patient who died of pulmonary conſumption, where little or no expectoration took place: and he cautions practitioners not to be miſled by ſuch an appearance, which is common in all congeſtions of the cheſt. He affirms, too, that a degree of jaundice is occaſionally produced, where the bile has free paſſage into the inteſtines, but is there detained, in conſequence of mechanical impediments, as *volvulus*, ſtrangulated *hernia*, accumulations of hardened fæces, &c. when it is taken up by the lacteals, and enters the blood-veſſels. On the other hand, he remarks, if we ſometimes attribute diſeaſes to the liver, which have their ſeat elſewhere, there are other maladies, actually ſeated in the liver, which are frequently aſcribed to other organs. Thus the contiguous *viſcera*, ſuch as the right kidney, the diaphragm, the lungs, the ſtomach, and the colon, are ſometimes ſuppoſed to be affected with diſeaſe, which is ſeated excluſively in the liver. Many examples of this are to be found in the writings of Morgagni and Lieutaud. Mr. Portal relates two caſes of ſevere and continued vomiting, connected with diſeaſed liver, the firſt of which proved fatal; and the other was cured, in conſequence of the leſſon taught by the previous diſſection. An enlargement of the liver was felt externally, with great tenderneſs in the epigaſtrium. See Mem. de l'Acad. des Sciences, Ann. 1777; or Mem. ſur pluſieurs Maladies, par Ant. Portal, tom. i. p. 228.

Where there is evidence of the exiſtence of a conſiderable degree of diſeaſe in the liver, the prognoſtic muſt be always unfavourable, on the whole: for, in the firſt place, it is extremely difficult to aſcertain the exact ſtate of the organ; and, ſecondly, if we actually knew it, the moſt judicious application of the moſt powerful remedies would be unequal ſometimes to remove the diſeaſe. The moſt favourable ſymptoms are, an improvement in the complexion, the ſtrength remaining unimpaired by the action of the medicines, and a return of appetite. Dr. Pemberton thinks that if the patient decidedly gains bulk in the ſolids of the body, you may ſafely pronounce that he will recover. The moſt unfavourable ſymptoms are, the colour of the ſkin remaining the ſame, or becoming more ſallow, the general ſtrength being much diminiſhed, the abdomen beginning to ſwell, and the patient loſing bulk in the upper extremities, while the lower become more enlarged. Pemberton on Diſ. of the Abdom. Viſcera, p. 43.

When the liver is ſo far diſeaſed as to have become ſchirrous, tubercular, or in any other way much altered in its ſtructure, it muſt be obvious that medicine cannot effect any eſſential change. The treatment, therefore, which is to be recommended muſt be conſidered as applying to that ſtage of diſeaſe, which precedes any extenſive organic alteration. It is not improbable, as Dr. Saunders ſuggeſts, that the original miſchief is commonly in the ſtomach and bowels, and that the liver becomes diſeaſed by ſympathy: for dyſpeptic complaints generally precede the chronic affections of the liver; and they are induced by intemperance in eating or drinking, but particularly by the abuſe of vinous and ſpirituous liquors, by long faſting, by a ſedentary mode of life, by grief and anxiety of mind, &c. (See DYSPEPSIA.) Whatever weakens the digeſtive powers of the ſtomach, Dr. Saunders maintains, ultimately weakens alſo the power of the liver, and diminiſhes the ſecretion of bile. (Saunders on the Liver, p. 192.) And again, he conſiders the diminiſhed ſecretion of bile, or its diminiſhed protruſion into the *duodenum*, (which he aſcribes to an hypothetical conſtriction of the bile-ducts,) as reciprocally acting upon the ſtomach, and weakening its tone. One proof of the exiſtence of the ſuppoſed ſpaſmodic conſtriction of the orifice of the common duct he deduces from an obſervation, that, in a fit of ſick head-ache, if bile is brought into the ſtomach, and thence ejected, by the violent ſtraining to vomit, the termination of the fit is much more ſpeedy and complete than when this does not happen.

When the diminiſhed or altered ſecretion of the bile, then, is preceded by affections of the ſtomach, ſuch as loſs of appetite, indigeſtion, and flatulent eructations, the diet of the patient ſhould be attentively regulated, the art of cookery ſhould be rendered merely ſubſervient to digeſtion, and the preparation of healthy chyle; and the general regimen ſhould be ſuch as has been already recommended in diſorders of the digeſtive organs. (See INDIGESTION.) The quantity of food taken at one time ſhould be moderate, and water ſhould be the only liquid drunk with the meals, as more effectually promoting digeſtion than fermented liquors of any kind. All raw or unboiled vegetables ſhould be avoided; but ripe fruits may be moderately taken, and almoſt all boiled vegetables admitted. Animal food ſhould be well boiled, or moderately roaſted, and taken with its own gravy. Pye-cruſt, every thing fried, butter rendered rancid by being melted, &c. ſhould be cautiouſly avoided. The patient ſhould uſe regular and moderate exerciſe.

It is of the higheſt importance, in order to keep up a due ſecretion of the bile, to adminiſter a ſucceſſion of gently purgative medicines. Upon this principle, the benefits ariſing from the waters of Cheltenham (which cannot be too highly recommended in theſe complaints) are obviouſly to be explained. Nevertheleſs, ſo far as the mere operation of theſe waters is concerned, no good reaſon can be aſſigned for any ſuperior efficacy to be expected from them rather than from the adminiſtration of an equally active doſe of the ſulphate of magneſia, or other ſaline laxatives, diſſolved in a proper quantity of water. Three drams of this ſalt in half a pint of fluid, as in the Seidlitz water prepared by N. Paul and Co., may be taken every morning, or every other morning, according to the ſtrength and ſtate of bowels of the patient. The regularity, temperance, and exerciſe, and likewiſe the abſence of the anxieties of buſineſs, which contribute materially to aſſiſt the beneficial influence of thoſe waters, when drunk at the ſprings, ſhould, however, be conjoined with the employment of theſe ſubſtitutes at home.

In the chronic derangements of the liver, producing a diminiſhed ſecretion of bile, and particularly when ſuch affections have ariſen from inflammation, mercury has been found one of the moſt effectual remedies. It is only, however, in the chronic ſtate of inflammation that this remedy is adminiſtered with advantage. But the ſucceſs of it, in theſe caſes, has led perhaps to an empirical practice, of exhibiting it without ſufficient diſcrimination between inflammations of a more indolent, and thoſe of a more active nature, on the one hand, and between inflammation and the tuberculated ſtate, &c. on the other. But, as Dr. Saunders remarks, to exhibit a medicine without due diſcrimination, is to abuſe it, and at length to bring it into contempt and neglect. And this fate may perhaps await the uſe of mercury in complaints of the liver, if, by a blind empirical adminiſtration of it, it be incautiouſly employed in the *active* periods of inflammation, when, from its ſtimulant properties, it appears better calculated to accelerate than to retard the ſuppurative proceſs. But upon this point we have enlarged, when treating of the cure of HEPATITIS; and ſhall now only repeat, that it is in the chronic ſtate of inflammation alone, that the exhibition of mercury can be reſorted to with benefit; for it now acts as a ſpur upon the vaſcular ſyſtem of the liver, and, by its moderately ſtimulating effects, occaſions at length a degree of action, by which the bile is properly elaborated, and health gradually reſtored.

That a great variety of complaints, both local and general, which have been comprehended under the terms nervous, hypochondriacal, bilious diſeaſes, &c. originate from diminiſhed ſecretion of bile, which, under ſuch diminution in quantity, is alſo liable to be vitiated in quality, practitioners are again coming to admit. By obſerving phyſicians of all times, indeed, this general fact had been noticed; and upon it, a principal part of the ancient humoral pathology, which aſcribed thoſe diſeaſes to the prevalence of *bile* and *black bile*, was founded. We cannot now, with all the additional lights afforded by a better cultivation of anatomy, phyſiology, and the collateral ſciences, lay down a perfect theory of the ſubject. A learned and ingenious phyſician to Guy's Hoſpital has long inveſtigated the point, and has long been pledged to lay the reſult of his practical inquiries before the public. They have not, however, yet appeared. But from the publication of a ſmall pamphlet, as the precurſor of his volume, it would appear that he has ſatisfied himſelf, both with reſpect to certain means of practical diſcrimination, and as to the mode of operation of the mercurial remedies. It would ſeem, from this pamphlet, that the author conſiders moſt of theſe diſeaſes as dependent on a conſtricted or obſtructed ſtate of the hepatic ducts, and mercury, adminiſtered in ſmall doſes, and in its milder forms, as poſſeſſing the property of "emulging" the ducts, eſpecially when irritation about the parts is ſoothed by opiates: in other words, that theſe mercurials are, in the ſtrict ſenſe of the word, *cholagogues*. After having deſcribed the caſe of a delicate female, affected with great irregularity of bowels, terminating in dyſentery, and accompanied with paleneſs, languor, dejection of ſpirits, loſs of appetite, quick ſmall pulſe, &c. which had been rather augmented than relieved, by repeated doſes of calomel and rhubarb, alternated with opiates, and which yielded to ſmall doſes of the *pilula hydrargyri*, preceded by an opiate, and followed by a doſe of caſtor-oil;—he thus ſtates his view of the diſeaſe, and of the *modus operandi* of theſe remedies. "The depreſſed action of the brain which anxiety occaſions, produced a correſponding defect of action in the liver; whence the inteſtines, from not being ſupplied with bile in ſufficient quantity, or healthy in quality, became irritated by the food paſſing through them in an undigeſted ſtate. The purgatives, aſtringents, and opiates, which were firſt employed, gave temporary relief, but left the *ſource* of the diſorder as it was; whilſt the calomel, acting merely as a ſimple evacuant, carried off nothing but the exiſting contents of the inteſtines, and ſtill farther weakened their tone. But, by allaying inteſtinal irritation by opium, then relaxing the hepatic ducts by the *pil. hydrargyri*, and laſtly, emulging them by the aid of a mild cathartic, the order of nature was reſtored, and that harmony of function between theſe parts, which is neceſſary to health, completely eſtabliſhed." (See An Examination of the Prejudices commonly entertained againſt Mercury, &c. by James Curry, M.D., &c. 2d edit. p. 20, note. Lond. 1810.) This explanation of the alleviation of the diſeaſe is ſufficiently plauſible; it is, however, but an hypotheſis; for the previous *conſtriction*, the ſubſequent *relaxation*, and the ultimate *emulging* of the biliary ducts, are incapable of demonſtration; neither is the firſt aſſumed circumſtance adequate to explain the altered quality of the bile, nor the two latter its changes to the healthy ſtate. It is ſufficient, however, if it be practically aſcertained, that this mode of mercurials, preceded or combined with anodynes, and followed by gentle cathartics, is an efficient mode of treatment in theſe caſes of diminiſhed or vitiated ſecretion of bile.

In thoſe caſes of diſeaſed liver, which have been ſometimes denominated ſchirrous, when, either from previous acute inflammation, or from frequent accelerated ſecretion of bile, during a long reſidence in a warm climate, the veſſels of the liver have poured out, into the parenchymatous ſubſtance, ſo much coagulable lymph, as to render it firm and indurated,—then it is often neceſſary to puſh the uſe of mercury farther, ſo as to produce a gentle ſalivation, which, when kept up for a length of time, often effects a cure, by promoting abſorption. In the exhibition of mercury for this purpoſe, a preference has been given to its introduction by friction on the ſkin, through the cutaneous abſorbents; and the part on which the mercurial ointment has been rubbed is the right *hypochondrium*, from a notion of its efficacy being greater when applied to the vicinity of the diſeaſed organ. But it is pretty obvious, that, except in ſo far as friction may ſerve the purpoſe of gentle exerciſe to the part, and thus aſſiſt in emulging the biliary ducts, there is no material advantage derived from this; and that it is of little importance what part is made choice of, provided the effects produced on the general ſyſtem be equally ſtrong. The knowledge derived from anatomy reſpecting the ſtructure, origin, and direction of the abſorbent veſſels, ſufficiently proves that, whether uſed internally, or introduced by external friction, none of the mercury can be made to paſs through the liver in its way into the conſtitution: it cannot, therefore, act on the liver, but by being firſt introduced into the blood-veſſels. Such parts of the body as have the fineſt cuticle, as in the inſide of the thighs, between the fingers, in the groin, &c. which afford the beſt abſorbing ſurface, ſhould be choſen for the purpoſe of the friction.

On the other hand, the tuberculated ſtate of the liver is perhaps always beyond the power of mercury to alleviate, and often it would ſeem even aggravated by its exhibition. Medicine may contribute greatly to relieve diſtreſſing ſymptoms, in ſuch caſes, but cannot be expected to change the morbid ſtructure. Flatulence, pains in the ſides, ſtomach, and belly, indigeſtion, &c. may be greatly diminiſhed by laxatives, abſorbents, gentle tonics, and occaſional antiſpaſmodics; and the digeſtion may be favoured by the choice of light diet, taken in moderate quantities. But it cannot be expected that the ſyſtem ſhall be put under the ſtimulus of a mercurial courſe with impunity, much leſs with advantage, under ſuch circumſtances.

Liver, *Infarctions of the.* See HEPATITIS *Infarctio.*

Liver, in *Antiquity*, was much uſed in divination. See Hepatoscopia.

Liver *of Antimony*, in *Chemiſtry*, reſults from the detonation of antimony with an equal weight of nitre. Theſe two matters reduced into powder are to be mixed together, and put into a large crucible. The maſs is then to be kindled, and the detonation to be made. When it has detonated it is to be kept in fuſion, and then cooled. When the crucible is broken, at the bottom two diſtinct matters are found, which may be ſeparated from each other by the ſtroke of a hammer. The upper matter is a ſaline ſcoria, nearly of the ſame nature as the ſcoria of the regulus of antimony. This is a true antimonial liver of ſulphur, mixed with a certain quantity of vitriolated tartar. The lower matter is heavier. It is opaque, compact, red, and brittle. This is the liver of antimony. Its colour and appearances have been ſuppoſed ſimilar to thoſe of the livers of animals, whence its name. It is principally compoſed of the metallic part of antimony, half deprived of its ſulphur, and dephlogiſticated by nitre. This ſubſtance is of no uſe in chemiſtry, nor in medicine, ſince the kermes mineral and emetic tartar have been introduced. Macquer's Chem. Dict. See Antimony.

Liver *of Arſenic*, is a combination of white arſenic with liquid fixed vegetable alkali, or by the humid way. The operation for making liver of arſenic is eaſy and ſimple: to ſtrong and concentrated liquid fixed alkali, previouſly heated, fine powder of white arſenic muſt be added, till the alkali is ſaturated, or has loſt its alkaline properties. While the alkali diſſolves the arſenic, it acquires a browniſh colour, and a ſingularly diſagreeable ſmell; and the mixture gradually thickens into a gluey conſiſtence. Chem. Dict. See Arsenic.

Liver *of Sulphur* is the combination of ſulphur with alkaline matters: and this combination may be made either in the dry or humid way. In the dry way, or by fuſion, a mixture of equal parts of fixed alkali and ſulphur is put into a crucible, and quickly fuſed. The melted maſs is then poured on a greaſed ſtone, and then the liver of ſulphur congeals and acquires a brown colour. If it be required to be kept dry, it muſt be ſoon broken to pieces, and put, while it is hot, in a bottle well corked, becauſe it readily imbibes moiſture from the air. In the humid way, which is leſs common, concentrated liquid fixed alkali, and fine powder of ſulphur, are to be boiled together, till the alkali has diſſolved as much as it can: the liquor is then to be filtrated and evaporated.

Liver of ſulphur is an important combination in chemiſtry, becauſe it is in general a very powerful ſolvent of metallic matters; to all which, excepting zinc, it attaches, particularly in fuſion. It ſeems to diſſolve gold more effectually than other metals. It diſſolves alſo vegetable coals even by the humid way: and the ſolution is of a green colour. Particular kinds of livers of ſulphur may be formed by the combination of volatile alkali, of quick-lime, or of abſorbent earths, all which attack ſulphur more or leſs. Chem. Dict. See Sulphur.

M. Navier has lately diſcovered, that the liver of ſulphur, and particularly of liver of ſulphur of Mars, hath the moſt ſalutary effects as an antidote againſt arſenic, corroſive ſublimate, verdigris, and lead. Nav. Contre Poiſons de l'Arſenic, &c. 1777. See Lead.

Liver-*ſtone* See Lapis *Hepaticus*.

Liver-*wort*, in *Botany*. See Lichen.

Liver-*wort*, *Noble*, *Hepatica*, a ſpecies of the anemone.

LIVERMORE, in *Geography*, a town of America, in Cumberland county, Maine, ſituated on both ſides of Androſcoggin river; 19 miles N.W. of Hallowell, and containing 863 inhabitants.

LIVERNON, a town of France, in the department of the Lot, and chief place of a canton, in the diſtrict of Figeac; eight miles W.N.W. of Figeac. The place contains 713, and the canton 7786 inhabitants, on a territory of 285 kiliometres, in 17 communes.

LIVERPOOL, a market town, borough, and ſea-port, in the county palatine of Lancaſter, England. It is placed on the eaſtern bank of the river Merſey, which flows into the Iriſh ſea, not far north of Liverpool. The population of this town, according to the parliamentary returns of 1800, amounted to 77,653 perſons, who occupied 11,446 houſes.

The etymology of the word Liverpool is much involved in obſcurity, though many ingenious antiquaries have endeavoured to aſcertain it. The moſt general opinion is, that it owes its origin to a ſpecies of bird called the *lever*, great flocks of which are ſaid to have frequented a pool in this neighbourhood, during their wanderings from their native climes. Accordingly a bird has, from time immemorial, been the impreſſion on the corporation ſeal. The early hiſtory of this town is equally as unknown as the derivation of its name. Fortunately, however, the deficiency of records concerning it cannot be felt as a great loſs, as there ſeems little reaſon to ſuppoſe it was of any importance, either commercially or politically, previous to the commencement of the laſt century; hence it may be called a modern town.

> "Yet ſcarce an hundred annual rounds have run,
> Since firſt the fabric of this power begun;
> His noble waves inglorious, Merſey roll'd,
> Nor felt his waves by labouring art control'd.
> Along his ſides a few ſmall cots were ſpread,
> His finny brood their humble tenants fed."
> Mount-Pleaſant, a poem by Roſcoe.

To the active, perſevering, and liberal conduct of the author of theſe lines, Liverpool is materially indebted for its preſent increaſe of buildings, commerce, &c. and it would have reflected credit on the free burgeſſes of the town, had they continued to elect him their member.

In the Conqueror's ſurvey, it is ſtated, that all the land between the rivers Ribble and Merſey belonged to Roger de Poictiers; but there is no mention either of a town or village. Hence it may be reaſonably ſuppoſed none exiſted at this time. A caſtle, however, is noticed by Camden, as having been built ſhortly after the conqueſt, the command of which was beſtowed on Vivian de Molyneaux, a Frenchman, in whoſe family it continued till the 30th year of the reign of queen Elizabeth.

Neither hiſtory nor tradition determine any thing certain, either concerning its founder or the period of its erection.

The tower, which forms part of a priſon in Water-ſtreet, is the only building of antiquity which Liverpool can now boaſt of poſſeſſing. The original founder of this tower we are as ignorant of as we are of the founder of the caſtle. Seacombe, in his Memoirs of the Stanley family, is the firſt author who mentions it. He tells us, that it was the property of ſir Thomas Latham, in the reign of Edward III., whoſe daughter and heireſs married ſir John Stanley; but ſays nothing of its erection. The croſs which formerly ſtood at the corner of Pinfold lane, oppoſite the Flaſhes, has been long demoliſhed. This tradition reports to have been placed there in commemoration of St. Patrick, who, it is ſaid, reſted in this neighbourhood on his way from England to Ireland.

The firſt charter in favour of Liverpool, according to Enfield, who publiſhed a hiſtory of Liverpool, was executed in the reign of Henry I., but the accuracy of this ſtatement is extremely doubtful. It is certain, however, that in the charter granted by king John in 1203, nearly a century afterwards, this town is called a borough by preſcription. Henry III. confirmed the privileges of the corporation in the year 1227. From this period to 1555, we are totally in the dark as to its hiſtory or condition; nor is there any thing worth remarking for the 16 years following, when the inhabitants ſent a memorial to queen Elizabeth, praying relief from a ſubſidy which her miniſters had impoſed upon them. In this petition they ſtyle themſelves "her majeſty's poor decayed town of Liverpool." How the town became ſo "decayed," it is now difficult to comprehend, as, from the records ſeveral years previous, it does not ſeem to have been any better than a fiſhing hamlet, containing about 138 houſeholders and cottagers, and poſſeſſing 12 barks, navigated by 75 men. Camden, however, who wrote in 1586, conſidered it in his time as more famous for its beauty and populouſneſs than for its antiquities. To reconcile theſe oppoſite ſtatements, it is only neceſſary to admit, that a very trifling village may arrive at conſiderable opulence in the ſhort period of 21 years; and who will deny the poſſibility of ſuch an event at the preſent day? From Camden's time nothing is recorded of Liverpool deſerving of notice till the year 1644; when the town and its caſtle were poſſeſſed by the parliamentary troops, under colonel Moore. It was fortified and ſecured on the land ſide by a high mud wall, and a ditch twelve yards wide and three deep. Batteries were erected at different points, and the ends of the ſtreets were defended by artillery. The garriſon was numerous, and being well ſtored with proviſions, made a moſt vigorous defence for the ſpace of a month. At laſt, however, the king's army, under the orders of prince Rupert, ſucceeded in taking the town, when the caſtle ſurrendered without further reſiſtance. Some traces of this ſiege can yet be diſcovered at different points. When the foundation of the preſent infirmary was ſunk, the marks of trenches were diſtinctly viſible, and many articles of modern warfare were found within their ſcope. A few years ago, as ſome workmen were removing the earth in a field where Glouceſter-ſtreet now ſtands, they laid open the foundation of a battery, and diſcovered military utenſils of different kinds. From the time of the ſiege till 1680, we have a tolerable account of the progreſs of the town in extent and population. After this period, however, we are again left in obſcurity, and receive no authentic information on that head till the year 1765, when we find a plan of the town made by Mr. John Eyes. About this time, ſays Enfield, Liverpool contained about 4200 houſes, and 25,000 inhabitants. It had, in the interval laſt-mentioned, been conſtituted a diſtinct pariſh from that of Walton, to which its church had formerly been only a dependent chapel. This event took place in 1698, when the inhabitants were likewiſe authoriſed to build a ſecond church. Thus emancipated from parochial ſubſerviency, Liverpool began to diſplay its energies. In the ſhort ſpace of little more than half a century, this town, aided by a few favourable circumſtances, has riſen to great commercial importance, and may be conſidered to be next to the metropolis itſelf. She firſt rivalled, and latterly ſurpaſſed, Briſtol, which had long been conſidered as the weſtern emporium of trade.

The following table exhibits the progreſſive increaſe of the dock duties for ſeveral years, and ſerves to diſplay the vaſt and rapid increaſe of the commerce of the town. It ſhews the number of veſſels that have been aſſeſſed in each year, with the aggregate ſum paid to the dock companies.

Years.	*Ships.*	*£.*	*s.*	*d.*
1760	1245	2,330	6	7
1765	1930	3,455	8	4
1770	2073	4,142	17	2

1802	4781	28,192	9	10
1805	4618	33,364	13	1
1807	5791	62,831	5	10
1809	6023	97,580	19	3

The boundaries of Liverpool extend conſiderably beyond the town in different directions. Theſe are marked out by ſtones called by the inhabitants meer-ſtones, and the ground contained within them is denominated the liberties. The extent of the liberties from eaſt to weſt, is ſomewhat more than a mile and two furlongs, and from north to ſouth conſiderably above two miles. This town exhibits, in general, the appearance of opulence and refinement. The ſtreets are well paved, and during winter tolerably furniſhed with lamps. Of late years it has received many great alterations and improvements, which ſtill continue to proceed notwithſtanding the preſſure of the times. In the year 1790, it conſiſted of 8865 houſes, but their number now is little ſhort of 13,000.

Liverpool poſſeſſes fifteen churches belonging to the eſtabliſhment, ſome of which are worthy the particular attention of the ſtranger. Near the old church, which is dedicated to our Lady and St. Nicholas, there formerly ſtood an image of the latter, to which the ſailors were accuſtomed to make offerings on going to ſea. This church has been lately rebuilt. The tower of St. Peter's, which was erected in 1704, is a well-proportioned octagon, each ſide of the angles having a candleſtick and gilt vaſe repreſenting a flame. This and St. Nicholas are the pariſh churches, and have two rectors over them. The church of St. George, built on the ſcite of the ancient caſtle already mentioned, is a fine edifice of the Doric order, crowned with an attic wall, and adorned with a variety of vaſes. On each ſide is a terrace with receſſes underneath. The interior is handſomely fitted up, the fronts of the galleries being mahogany. This is the mayor's chapel, where he attends every Sunday, and where pews are appropriated for the gentlemen, including ſtrangers, who chooſe to accompany him. St. Thomas's church is of the Ionic order, and has a handſome appearance. It was conſecrated in 1750. St. Paul's church was erected by the town in 1769. At the weſt end is a portico with a pediment, having in the centre, on an octagonal baſe, a dome with a lanthorn, ball, and croſs. The interior is ſupported by eight Ionic pillars. The altar is plain and neat. The church dedicated to St. Ann, on the road to Everton, is a neat building of brick and ſtone. It was erected at the joint expence of two private gentlemen. It has a tower decorated with pinnacles. St. John's church is a new building of ſtone, with a tower. St. Mary's and the other churches have nothing connected with their ſtructures or appearances deſerving of particular notice; though all of them are entitled to be called neat. Beſides the places of worſhip belonging to the eſtabliſhment, there are a great number of diſſenting meeting houſes, or chapels, for various deſcriptions of religioniſts.

The public edifices connected with the trade and commerce of the town are, the exchange buildings, town-hall and manſion houſe, cuſtom-houſe, corn exchange, tobacco warehouſe, and other warehouſes. Of theſe the Liverpool exchange is the moſt ſpacious in plan, and ornamental in its exterior architecture. It has been erected by a ſubſcription of 80,000*l.* raiſed by 800 transferable ſhares. The buildings occupy three ſides of a quadrangle, having the town-hall on the ſouth ſide. The whole ſurrounds an area of 194 feet by 180. It has been Built by John Forſter, eſq. (architect, engineer, and dock maſter to the corporation) from deſigns by James Wyatt, eſq. architect; and is appropriated to a public exchange rooms, coffee rooms, and various offices. The town-hall, formerly called the exchange, is a large inſulated pile of building, the greater part of which was erected in 1750, from the deſigns of Wood of Bath. The whole of its interior was burnt in 1795. It was ſoon repaired, and appropriated to the uſe of the mayor, for offices belonging to the corporation, ſeſſions rooms, &c.

The infirmary is another excellent building of brick ornamented with ſtone. This eſtabliſhment not only extends to all proper objects within Liverpool, but to every perſon whom ſickneſs or bodily misfortune may lead to apply, provided they are recommended by a ſubſcriber. The ſeamen's hoſpital forms a portion of the buildings of this infirmary, being attached to it by a handſome colonnade. The blue-coat hoſpital is placed in an airy ſituation adjoining to St. Peter's church-yard. It is a large handſome building of brick ornamented with ſtone. The number of perſons who annually receive the benefits of this charity are about 280. The expence of this inſtitution is defrayed chiefly by benefactions.

The poor-houſe is a handſome edifice, 90 feet long and 24 broad, built in a plain ſtyle, and in a manner very ſuitable to its uſe. On the eaſt ſide of this ſtructure is a handſome ſtone building, called the "recovery ward," where perſons infected with fevers, and coming under the cognizance of phyſicians and ſurgeons of the diſpenſary, are received. A variety of alms-houſes range out on both ſides of the poor-houſe. In Church-ſtreet is the diſpenſary, which is a very good brick building, with a large circular portico, and having in front a ſmall bas-relief of the good Samaritan. This inſtitution is conducted by a preſident, two auditors, ſeven phyſicians, three ſurgeons, and one apothecary, who officiates as ſecretary. Two phyſicians and a ſurgeon attend every day at certain hours. About 10,000 perſons are ſaid to receive medicine and advice here annually. The Lunatic-aſylum is contiguous to the infirmary, but, like moſt other inſtitutions of the kind, cannot be called a complete charity, as patients are not admitted free of expence. At the entrance into the town, on the road leading from Preſcot, ſtands the ſchool of induſtry for the indigent blind. The original projector was Mr. John Chriſtie, who was himſelf unfortunately deprived of his ſight at the age of 19. In this ſchool pupils are taught various trades, which enable many of them to make a comfortable proviſion for life. Beſides theſe charitable inſtitutions there are a number of others, under different names, intended for the relief of different deſcriptions of perſons, which the limits of an article like this will not permit us to mention particularly.

Liverpool abounds, as may be ſuppoſed from its great trade, with rooms appropriated for public correſpondence, and the tranſacting of buſineſs. The Atheneum, which compriſes a news-room, a library, &c. is ſituated on the ſouth ſide of Church-ſtreet, and is a handſome building of ſtone. The ſubſcribers to this inſtitution, about 450 in number, are ſupplied with the London and provincial newſpapers, the ſhipping and trade liſts, and various periodical publications. Every ſubſcriber is allowed the privilege of introducing his friend, provided he be a non-reſident of the town. There alſo ſeveral more inſtitutions of a ſimilar kind in different parts of the town. Of theſe, the Lyceum is the firſt and moſt worthy of attention. It is ſituated at the bottom of Bold-ſtreet, and is another remarkable inſtance of the munificence and public ſpirit of Liverpool. An academy, for the encouragement of the fine arts, has recently been eſtabliſhed in this town. The places of public amuſement are now little inferior to thoſe in the metropolis. The theatre is a ſpacious and commodious building, and but little inferior to that of Covent-garden in the extent of its ſtage. It generally opens at the time the London houſes ſhut, when many of the firſt performers reſort to it. In Bold-ſtreet ſtands the Muſic-hall, which was opened in 1785. It is a large building, finiſhed with great elegance. The new priſon, according to the Howardian plan for ſolitary confinement, is on a very extenſive ſcale, and has every poſſible convenience.

Liverpool abounds in docks for the ſafety and repair of its numerous ſhipping. The firſt dock was conſtructed here in 1710. Its ſcite was the pool, from which the town derived the latter portion of its name. This baſon of water is called the old dock, and is principally the receptacle of Weſt India and African ſhips, being contiguous to the warehouſes of the merchants engaged in thoſe branches of commerce. The King's dock is 290 yards in length, and 90 wide. On the eaſt ſide of this dock ſtands the tobacco warehouſe, where that article is lodged by the cuſtom-houſe officers till the duties are paid. It was erected by the corporation, and is rented by government at 500*l. per annum.* St. George's dock was the third made in Liverpool. It is about 250 yards long, and 100 broad; and is eſteemed commodious. The largeſt, laſt conſtructed, and beſt finiſhed however of the Liverpool docks, is the Queen's dock, which is ſituated at the bottom of Parliament-ſtreet. Salt-houſe dock, which is the ſecond oldeſt of the whole, compriſes an area of 21,928 ſquare yards; and has a length of quay of 640 yards. Beſides theſe there are five graving docks, and three dry docks, independent of a ſmall one, which belongs to the earl of Bridgewater, for the uſe of the canal flats. Some of theſe docks communicate, ſo that ſhips can paſs from one to the other, and into the graving docks, without being obliged to go into the river. All the wet docks are likewiſe connected by large tunnels, for the purpoſe of one dock cleanſing or waſhing another. When large ſhips loaded arrive at neap tides they are compelled to remain in the river till the flow of the ſpring tides, as the dock gates have not depth of water ſufficient to admit them. This circumſtance is certainly a great inconvenience, but it is amply compenſated by the capaciouſneſs and excellent arrangement of the docks themſelves.

The cuſtom-houſe is ſituated at the eaſt end of the old dock. It is built of brick, in rather a neat ſtyle. A ſmall flight of ſteps leads to a piazza, over which is the long room, and behind it are extenſive warehouſes. At the ſouth end of the town is St. James's walk, from which the ſpectator has a fine view of the town, the harbour, the river, the ſea, and the Welſh mountains. Behind this lies an excellent quarry, the entrance of which is by a ſubterraneous paſſage, ſupported by arches. Bootle-ſprings, about four miles diſtant from Liverpool, ſupply the town with water, which is conveyed by means of pipes.

The principal manufactures are thoſe of china and earthen ware, the ſeveral branches of the watch making, and extenſive ſalt, iron, and copperas works. It is computed that about 3000 ſhipwrights are conſtantly employed in the different dock-yards of this town. The river, which is here about 1200 yards broad, abounds with ſalmon, cod, flounders, and turbot. Ships of any burden may come up to this town with perfect ſafety, even at the loweſt tides. The accommodations for ſea-bathing have, of late years, received vaſt improvements, and are not perhaps inferior to any in the kingdom.

Liverpool undoubtedly owes all her opulence and grandeur to the ſpirit and enterpriſe of her merchants. She exhibits, to the eye of the ſtateſman and philoſopher, a diſtinguiſhed inſtance of the rapid progreſs of commercial greatneſs. A century ago, a few coaſting veſſels and petty traders formed the whole of her wealth. For the firſt fifty years her advance was comparatively ſlow. After this period, however, the increaſe of trade which ſhe every year acquires, is truly aſtoniſhing. She ſhares a portion of the commerce of almoſt every country in the world. Of late years, Liverpool has conſiderably decreaſed, in common with that of all the other towns in the kingdom. What effect the abolition of the ſlave-trade may ultimately have upon Liverpool, it is not poſſible to prognoſticate. For the preſent, however, the mercantile houſes, formerly engaged in that traffic, muſt undoubtedly ſuffer conſiderable difficulties before they can turn their capital and attention to ſome object more honourable than the purchaſe and ſale of human beings.

Independent of the advantages Liverpool poſſeſſes for foreign commerce, it has communication with all the interior counties by canals. Theſe again, being joined by others at different points, extend themſelves to the Severn, to the Humber, and to the Thames; thus connecting the four principal trading ports in England. To the beneficial effects of theſe canals Liverpool has to attribute much of her preſent greatneſs.

The markets of Liverpool are well ſupplied with every neceſſary of life, and every article of luxury. About 3000 cattle and ſheep are brought into the town weekly. The market days are Wedneſdays and Saturdays. Liverpool ſends two members to parliament. The number of electors amounts to above one thouſand. The corporation conſiſts of a mayor, two bailiffs, and a common-council. The mayor and bailiffs are aſſiſted by a recorder, a town clerk, and other neceſſary officers. The revenues of the town are very great. Enfield's Hiſtory, &c. of Liverpool, folio. A General and Deſcriptive Hiſtory of Liverpool, by Wallace, 8vo. 1797. The Picture of Liverpool, 12mo. 1805. Beauties of England, vol. ix.

Liverpool, a town on the S. ſide of the bay of Fundy, in Queen's county, Nova Scotia, ſettled from New England. Between this town and Annapolis lies a conſiderable lake, called Roſſignol. It is 32 miles N.E. of Shelburne, and 58 N.W. of Halifax, and was formerly called "Port Roſſignole."

LIVERY, properly ſignifies a colour, to which a perſon has ſome particular fancy, and by which he chooſes to diſtinguiſh himſelf, or his retainers, from others.

Liveries are uſually taken from fancy, or continued in families by ſucceſſion. The ancient cavaliers, at their tournaments, diſtinguiſhed themſelves by wearing the liveries of their miſtreſſes: thus people of quality make their domeſtics wear their livery.

Father Meneſtrier, in his Treatiſe of Carouſals, has given a very ample account of the mixtures of colours in liveries. Dion tells us, that Œnamaus was the firſt who invented green and blue colours for the troops which, in the Circus, were to repreſent land and ſea-fights.

The Romiſh church has alſo her ſeveral colours and liveries; white, for confeſſors and virgins, and in times of rejoicing; black, for the dead; red, for the apoſtles and martyrs; blue or violet, for penitents; and green, in times of hope.

Formerly, great men gave liveries to ſeveral, who were not of their family or ſervants, to engage them in their quarrels for that year; but this was prohibited by the ſtatutes 1 Rich. II. 1 Hen. IV. cap. 27. 2 & 7 Hen. IV. 8 Hen. VI. cap. 4. 8 Ed. IV. cap. 2. and no man, of whatever condition, was allowed to give any livery, but to his domeſtic officers, and council learned in the law. However, moſt of the above ſtatutes are repealed by 3 Car. I. cap. 4.

Livery, in *Law*, alſo denotes the delivery of poſſeſſion to thoſe tenants which held of the king in capite, or by knights' ſervice. See Possession.

Livery is alſo uſed for the writ, which lies for an heir to obtain the poſſeſſion or ſeiſin of his lands at the king's hands. By 12 Car. II. cap. 24. all wardſhips, liveries, &c. are taken away. See Court *of Wards*.

Livery *of ſeiſin*, is a delivery of poſſeſſion of land or tenements, or things corporeal, to him who hath right, or probability of right, to them.

Livery of ſeiſin is a ceremony uſed in the common law, on conveyance of lands, tenements, &c. where an eſtate in fee-ſimple, fee-tail, or other freehold, ſhall paſs; and is a teſtimonial of the willing departing of him who makes the livery, from the thing whereof the livery is made, as well as of a willing acceptance by the other party, of all that whereof the firſt has diveſted himſelf. (See Freehold.) On the creation of a freehold remainder, at one and the ſame time with a particular eſtate for years, at the common law livery muſt be made to the particular tenant. (See Estate and Remainder.) But if ſuch a remainder be created afterwards, expectant on a leaſe for years now in being, the livery muſt not be made to the leſſee for years, for then it operates nothing; "Nam quod ſemel meum eſt, amplius meum eſſe non poteſt;" but it muſt be made to the remainder-man himſelf, by conſent of the leſſee for years: for without his conſent no livery of the poſſeſſion can be given (Co. Litt. 48.); partly becauſe ſuch forcible livery would be an ejectment of the tenant from his term, and partly for the reaſons aſſigned for introducing the doctrine of attornments.

Livery of ſeiſin is either in *deed* or in *law*.

The uſual manner of livery of ſeiſin in *deed* is thus performed. If it be in the open field, where is no houſe nor building, and if the eſtate paſs by deed, the feoffor, leſſor, or his attorney, openly reads it, or declares the effect of it; and after that is ſealed, the feoffor takes it in his hand, with a clod of earth, or a twig or bough, which he delivers to the feoffee, in the name of poſſeſſion, or ſeiſin, according to the purport of the deed. If there be a houſe or building on the land, the ceremony is to be done at the door of it, none being then left within; and the ring or latch of the door is delivered to the feoffee, who enters alone, ſhuts the door, and preſently opens it again. If it be a houſe without land or ground, the livery is made, and poſſeſſion given, by delivery of the ring or latch of the door and deed only; and where it is without deed either of lands or tenements, there the party declares by word of mouth, before witneſſes, the eſtate he parts with; and then delivers ſeiſin, or poſſeſſion, as aforeſaid: in which caſe the land paſſes as well as by deed, by virtue of the livery of ſeiſin. Co. Litt. 48. Weſt Symb. 251.

If the conveyance or feoffment be of divers lands, ſcattered in one and the ſame county, livery of ſeiſin of any parcel in the name of the reſt, ſufficeth for all (Litt. § 414.); but if they be in ſeveral counties, there muſt be as many liveries as there are counties. If the lands be out on leaſe, though all lie in the ſame county, there muſt be as many liveries as there are tenants. (Dyer 18.) In all theſe caſes it is prudent to endorſe the livery of ſeiſin on the back of the deed, ſpecifying the manner, time, and place of making it, together with the names of the witneſſes. Livery in *law* is where the ſame is not made *on* the land, but only *in ſight* of it; the feoffor ſaying to the feoffee, "I give you yonder land, enter and take poſſeſſion." However, this livery in law cannot be given or received by attorney, but only by the parties themſelves. Co. Litt. 48. 52.

Anciently, there were a pair of gloves, a ring, knife, an ear of wheat, &c. delivered in ſign of livery and ſeiſin.

LIVERYMEN *of London*, are a number of perſons choſen out of the freemen of each company. (See Company.) Out of this body the common-council, ſheriffs, aldermen, and other officers for the government of the city are elected; and they only have the privilege of giving their votes in common-hall for members of parliament, &c. from which the reſt of the citizens are excluded. If any one of the company refuſe to become a liveryman, he may be fined, and an action of debt will lie for the ſum.

Liverymen, in *Natural Hiſtory*, a name given by authors to a ſort of caterpillars, remarkable for their variety of colours. Theſe are of that claſs of caterpillars which live in communities, and build themſelves neſts to defend them from the injuries of the weather. They may be ranked among the proceſſionary kinds, always following one another with great order in their marches; but what is moſt ſurpriſing, is to ſee them ſtraggle very far from their neſts, and this often, by ſeveral repeated windings and turnings, without loſing their way. Their art, in doing this, deſerves notice, and is the ſame by which Theſeus got out of the labyrinth of Crete. Phil. Tranſ. N° 470. p. 459.

LIVIA Drusilla, in *Biography*, a celebrated Roman lady, daughter of Livius Druſus Calidianus, who joined the party of Brutus and Caſſius, and killed himſelf after the battle of Philippi. She married Tiberius Claudius Nero, by whom ſhe had two ſons, Druſus and the emperor Tiberius. The attachment of her huſband to the cauſe of Antony was the beginning of her greatneſs. Octavianus, afterwards the emperor Auguſtus, ſaw her as ſhe fled from the danger which threatened her huſband, and reſolved to marry her, though ſhe was then pregnant. He accordingly divorced his wife Scribonia, and with the approbation of the augurs he celebrated his nuptials with Livia. She from this moment enjoyed the entire confidence of the emperor, and was in fact the partner of his whole reign, enjoying a large ſhare of his power and imperial dignity. She gained a complete aſcendancy over the mind of Auguſtus by a conſtant obedience to his will: by never expreſſing a deſire to dive into his ſecrets, and by affecting ignorance of his amours. Her children by Druſus were adopted as his own by the complying emperor; and that ſhe might make the ſucceſſion of her ſon Tiberius, Druſus being dead, more eaſy and undiſputed, Livia has been accuſed of ſecretly involving, in one common ruin, the heirs and neareſt relations of Auguſtus. There are facts adduced which ſeem to render the ſuſpicions of her baſeneſs and cruelty wholly without foundation. She has been charged with adminiſtering poiſon to her huſband, which is rendered exceedingly improbable by the account we have of his laſt illneſs, and by the tenderneſs he expreſſed for her in the laſt words he uttered. By his will ſhe was inſtituted coheireſs with Tiberius, adopted as a daughter, and directed to aſſume the name of Julia Auguſta. On his deification ſhe became the prieſteſs of the new god. Tiberius, whoſe elevation had been the object of her policy, diſappointed her expectation of ſharing with him the imperial power. He took pains indeed to ſubject her to various mortifications; and at length there was an open rupture between them. She died in the year 29.

Tiberius neglected her funeral, and would not permit public or private honours to be paid to her memory. Tacitus has drawn her character, ſaying, that "in ſtrictneſs of conduct ſhe was not inferior to the Roman matrons of old, though her demeanour was freer than they would have approved; that ſhe was an imperious mother, a compliant wife, and a match for her huſband in art, and her ſon in diſſimulation."

Livia, in *Ornithology*, a name given by ſome authors to a particular ſpecies of pigeon called *pelæas* by the Greeks. It is very like the common pigeon in ſhape, but is ſomewhat ſmaller, its legs are red, and its beak white, except that it is a little purpliſh about the noſtrils.

It is all over grey, but that the end of its tail-feathers are black, and there is a purpliſh and greeniſh variegation about the ſides and ſhoulders. And its wing-feathers have ſome white variegations, as has alſo the lower part of the neck. It is ſuppoſed by Mr. Ray, and ſome others, to be the ſame with the *ſaſſorolla* of the Italians, or *columba rupicola*. See Columba.

LIVINEIUS, John, in *Biography*, a learned Flemiſh divine, was born at Dendermond about the year 1540. Being intended for the church, he purſued his academical ſtudies at Cologne, entered into holy orders, and was in a ſhort time preſented to a rich benefice at Liege. He was afterwards promoted to a canonry and appointed precentor in the cathedral church of that city. He engaged in the ſuperintendance of the edition of Plantin's Greek bible, and tranſlated into Latin ſome of the works of the Greek fathers, and was about giving to the public all the works of St. Gregory of Nyſſen, when he was cut off by death in 1599. He publiſhed "Emendationes et Notæ in XII. Panegyricos Veteres," and other learned works: and left behind him in MS. tranſlations of the tragedies of Euripides, and of the works of Athenæus. Gen. Biog.

LIVINETHAL, in *Geography*. See Levantine *Valley*.

LIVINGSTON, a county of Kentucky, in America, bounded N. by the Ohio, W. by the Miſſiſſippi, and S. by Teneſſee; 70 miles long and 60 broad. The principal rivers are the Cumberland and Teneſſee. It contains 2787 inhabitants, of whom 444 are ſlaves. Alſo, a large townſhip in Columbia county, New York, extending from the E. bank of Hudſon river to the Maſſachuſetts line, S. of Hudſon adjoining. It contains 7405 inhabitants, of whom 213 are ſlaves.

LIVISTONA, in *Botany*, named by Mr. Brown, in memory of the right honourable Patrick Murray, lord Liviſtone, the friend of ſir Andrew Balfour, who, when the Edinburgh botanic garden was firſt eſtabliſhed, greatly enriched it from his own private collection, where he had above a thouſand ſpecies in cultivation. This nobleman travelled over France in ſearch of plants, where he died of a fever, about the middle of the ſeventeenth century.—Brown Prodr. Nov. Holl. v. 1. 267.—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Palmæ*.

Eſſ. Ch. Calyx deeply three-cleft. Corolla deeply three-cleft. Filaments ſeparate, dilated at their baſe. Germens three, cohering. Styles three, united into one. Stigma undivided. Berry ſolitary, of one cell. Seed ſolitary; albumen with a ventral cavity; embryo at the back.

A genus of Palms, whoſe leaves are palmate, or ſomewhat pinnate, their ſegments cloven at the extremities. It ſhould ſtand between *Corypha* and *Chamærops*. *Latania chinenſis* of Jacquin's *Fragmenta*, p. 16. t. 11. f. 1, is thought by Mr. Brown to belong to this genus. Two ſpecies of it were found by him in the tropical part of New Holland.

1. L. *inermis*. Segments of the leaves with intermediate threads. Footſtalks without thorns. Stem from 14 to 30 feet high.

2. L. *humilis*. Segments of the leaves with intermediate threads. Footſtalks thorny. Stem from four to ſix feet high.

LIVIUS ANDRONICUS, in *Biography*, is regarded as the moſt ancient of the Roman poets. He was the firſt who attempted to compoſe a drama in verſe, which he himſelf ſung and acted, while a player on the flute accompanied him in uniſon to keep him in tune. He was encored and obliged to repeat his pieces ſo often, that he loſt his voice; and being unable to ſing or declaim any longer, he was allowed to have a ſlave to ſing, while he only acted the part behind him. Hence came the cuſtom of dividing the declamation or melody of the piece, with which the Roman people were extremely delighted. This poet flouriſhed 240 B. C. Livy and Prieſtley.

LIUNG, in *Geography*, a town of Sweden, in Weſt Gothland; eight miles S. of Uddevalla.—Alſo, a town of Sweden, in Eaſt Gothland; eight miles N.N.W. of Linkioping.

LIUNGBY, a town of Sweden, in the province of Skonen; 16 miles E. of Helſingborg.

LIVNI, a town of Ruſſia, in the government of Orel, on the Soſva; 84 miles E. of Orel. N. lat. 52° 58′. E. long. 38° 22′.

LIV OE, a ſmall iſland of Denmark, in Lymfiord gulf; having upon it a village. N. lat. 56° 53′. E. long. 9° 6′.

LIVONIA, the name of an ancient province of Ruſſia, which, including *Eſthonia* (which ſee), lies in N. lat. 58°, and is bounded on the N. by the gulf of Finland, on the E. by Novogorod, on the S. by Poland, and on the W. by the Baltic; being 190 miles from N. to S., and 180 from W. to E., and containing 725,300 inhabitants. This province abounds in lakes, foreſts, marſhes, and rivers; but many diſtricts are exceedingly fertile, yielding great quantities of rye and other grain, flax, hemp, and linſeed, which are exported to Sweden, Germany, and other countries; ſo that Livonia has been called the granary of the north. It has ſeveral good harbours conveniently ſituated for trade. Peipus lake, about 15 leagues long, and ten broad, has a communication with the gulf of Finland by the river Narva. This country, formerly claimed by ſeveral neighbouring princes, frequently changed maſters. Livonia, or Lettland, as it was called, together with Eſthonia, Courland, and Semigallia, being provinces on the Baltic, belonged in the earlieſt times to the Ruſſian ſtate, and had even a ſhare in the founding of it. (See LETTES.) But Livonia had then no ſettled conſtitution, nor was it bound to the parent ſtate by any firm political tie. To the reſt of Europe it remained generally unknown, till in the year 1158 it was diſcovered by ſome merchants of Bremen, in their ſearch of new branches of commerce towards the north. Theſe mariners landed at the mouth of the Duna, opened a trade with the inhabitants, returned thither ſeveral times, and at length proceeded, with the conſent of the natives, along the ſhores of the Duna, or Dwina, many miles up the country. About eighteen years after the diſcovery, an Auguſtine monk, named Meinhard, ſettled in Livonia, proſelyted the Livonians to Chriſtianity, and became their biſhop, upon which many Germans, at various times, were induced to repair thither alſo. The time of the arrival of Meinhard is not preciſely aſcertained. Some pretend that it was in 1170, others in 1186. The ſucceſs of the monk was promoted by the ſervice which he rendered to his own countrymen, in repulſing the Lithuanians, who had made an incurſion upon them. He ſtated to them the neceſſity of conſtructing a ſtrong fortreſs, and he aided them in accompliſhing this object, on condition of their being baptized. But they were reluctant in complying with this condition, and many of them relapſed to Paganiſm. Meinhard was diſappointed in his benevolent efforts, and prevented by force from returning with his clergy to Germany, he died among them, more of grief than of age. After his death, Berthold, abbot of the monaſtery of Lockum, in Hanover, was elected biſhop, and arriving in Livonia, though not without reluctance, in the year 1197, he recommended himſelf by giving them frequent entertainments: but the ardour of their attachment ſoon abated, and he was conſtrained by ill uſage to leave the country. He applied to Gothland and to Lower Saxony for ſuccour; and the pope aſſiſted him by cauſing a cruſade to be preached againſt the heathens of Livonia. In 1198 he returned hither with an army of ſoldiers. The Livonians prepared to fight, took the field to reſiſt the invaders. A truce was concluded, which was ſoon broken on the part of the heathens, by the aſſaſſination of ſeveral Germans. Berthold declared war, and in a bloody battle which enſued, fell by the ſword. The heathens, however, were at length routed, and when their corn-fields were laid waſte by the Chriſtians, they ſued for peace, and flocked in numbers to be baptized. Upon this the Germans returned home; but they were no ſooner embarked, than the Livonians bathed in the Dwina, in order, as they ſaid, to waſh away their baptiſm and Chriſtianity together. They alſo plundered thoſe that remained, and put upwards of 100 to death. The Livonians alſo reſolved, that all prieſts who ſhould be found in the country after Eaſter 1199, ſhould be ſlain. A ſimilar fate alſo awaited the merchants. Theſe ranſomed their lives, but the clergy were forced to fly to Lower Saxony. The monk Meinhard, and the abbot Berthold, were ſucceeded by Albrecht, who, being elected biſhop, arrived in Livonia with twenty-three ſhips. The Livonians became Chriſtians for fear of ſtarving. Albrecht employed valiant men, from whom the biſhopric might expect continual protection; and with this view he gave ample fiefs to ſome courageous nobles. He eſtabliſhed alſo a ſtanding army, and deviſed other methods for eſtabliſhing Chriſtianity in the country. In 1201 he built the city of Riga, and transferred hither the cathedral chapter, where he alſo built a monaſtery. In the mean while the clergy diſperſed themſelves through the country, in order to teach and to baptize. In proceſs of time other means were uſed to accompliſh the converſion of the Livonians.

nians. In the year 1205 Andrew, archbiſhop of Lunden, viſited Riga, and having acquired the reputation of a learned divine by his ſtudies in Italy, France, and England, gave lectures of theology to the clergy of that city; and by his advice the vicar of the biſhop of Riga ſent prieſts among the Livonians, divided the country into diſtinct pariſhes, and cauſed them not merely to be baptiſed, but to be previouſly inſtructed. Churches were alſo erected. From Livonia Chriſtianity was diffuſed, againſt much oppoſition, among the Eſthonians. In the year 1522, the reformation found its way into Liefland, by a preacher, who, having been driven out of Pomerania, fled to Riga. The doctrine of Luther was eagerly embraced; and the Popiſh ritual, afterwards patronized on the part of Poland, had, on the whole, no influence to its detriment. By the tenth article of the treaty of Nyſtadt, the Greek religion is ſecured in the free exerciſe of its rites. In Riga there is a church for the uſe of the Calviniſts, and the Catholics are allowed the exerciſe of their worſhip. In Liefland it may be juſtly ſaid that every man may follow his own perſuaſion in matters of religion without the leaſt moleſtation. Here alſo count Zinzendorf has found many friends to his church inſtitution.

Soon after the converſion of the Livonians, the biſhop, in the year 1201, founded the order of the Sword-brethren, afterwards called Knights-Templars, and granted them the third part of the country with all rights of ſovereignty, for conquering and preſerving Livonia. Theſe knights were all Germans, who proſelyted the natives to Chriſtianity with great ſucceſs, though not without bloodſhed, and made them their vaſſals. They afterwards united themſelves with the Teutonic order in Pruſſia, to whom Valdimar III., king of Denmark, in 1386, ſold Eſthonia for the ſum of 18,000 marks of ſtandard gold. In the year 1521 the Livonian heermeiſter Plettenberg again ſeparated from the Teutonic order, and was admitted by the emperor Charles V. among the princes of the German empire. The attempts made by Czar Ivan Vaſſillievitch II. to reconquer theſe provinces which had been torn from the Ruſſian empire, and the weakneſs of the order, which felt itſelf not in a capacity to reſiſt ſo powerful an enemy, at length, in 1561, effected the complete ſeparation of the Livonian ſtate. Eſthonia put itſelf under the protection of Sweden, Livonia united with Poland, and Courland was a peculiar dukedom under Poliſh ſupremacy, which the laſt heermeiſter Gotthard Kettler held as a fief of that crown. From this era Livonia became the unhappy object of contention, for which Sweden, Ruſſia, and Poland, for an entire century, were continually exhauſting themſelves in bloody wars. Sweden at laſt obtained the dominion, and at the peace of Oliva in 1660 added this province to the poſſeſſion of Eſthonia. Both countries finally, after a war of 20 years, came to the Ruſſians by the treaty of Nyſtadt in 1721; and form at preſent the viceroyalties of Riga and Revel. Theſe two governments are ſuppoſed to contain 24,000 geographical ſquare miles. This country formerly contained a conſiderable number of towns and villages, but by wars and inteſtine commotions, moſt of them were deſtroyed. See Riga and Revel.

The tract of country called Poliſh Livonia, which, under the government of the Teutonic order, formed likewiſe a part of the Livonian ſtate, reverted in the year 1561, with the whole province of that name, to Poland. At the peace of Oliva, by which Livonia came under the ſovereignty of Sweden, this ſole diſtrict however remained to the Poliſh ſtate, retaining from that time its name in contradiſtinction to Swediſh Livonia. On the partition in 1773, this country, which had hitherto conſtituted its particular voivodeſhip, was annexed to Ruſſia, and now comprehends the two circles of Dunaburg and Reſitza, in the viceroyalty of Polotſk. Tooke's View of the Ruſſian Empire, vol. i.

LIVONICA Terra, in the *Materia Medica*, a kind of fine bole uſed in the ſhops of Germany and Italy, of which there are two ſpecies, the yellow and the red. (See Bole.) The diſtinguiſhing characters of which are theſe.

The yellow Livonian earth is a pure and perfectly fine bole, of a ſhattery friable texture, conſiderably heavy, and of a dull duſky yellow, which has uſually ſome faint bluſh of redneſs in it. It is of a ſmooth ſurface, and does not ſtain the hands; it adheres firmly to the tongue, and melts freely in the mouth, leaving no grittineſs between the teeth, and ferments not at all with acid menſtrua. In a moderate fire it acquires ſome additional hardneſs, and a darker colour. It has been eſteemed a ſudorific and an aſtringent.

The red Livonian earth is an impure bole of a looſe texture, and a dull red. It is of a ſmooth ſurface, breaks eaſily between the fingers, and ſlightly ſtains the hands. It melts freely in the mouth, has a very ſtrong aſtringent taſte, but leaves a grittineſs between the teeth, and is alkaline. It acquires a conſiderable hardneſs in the fire, and becomes of a paler colour with a ſtrong caſt of yellowiſh-brown.

Theſe earths are both dug out of the ſame pit, in the place from whence they have their name, and in ſome other parts of the world. They are generally brought to us made up in little cakes, and ſealed with the impreſſion of a church, and an eſcutcheon with two croſs keys, and recommended in diarrhœas, dyſenteries, &c.

LIVORNINA, an old coin of Leghorn, equal in value to *4s.* $5\frac{1}{2}$*d.* ſterling.

LIVORNO, in *Geography*. See Leghorn.

LIUR, a town of Sweden, in Weſt Gothland; 33 miles N.E. of Gotheborg.

LIVRE, a French money of account, in the old ſyſtem, conſiſting of twenty ſols; each ſol containing twelve deniers and four liards.

The origin of the word is derived hence, that anciently the Roman libra, or pound, was the ſtandard by which the French money was regulated; twenty ſols being made equal to the libra. By degrees the libra became a term of account; ſo that any coin juſt worth twenty ſols was a livre, or libra; and ſince the time of Charlemagne, all contracts have been made on the foot of this imaginary coin; though the ſols have frequently changed their weight and alloy.

The livre is of two kinds, *Tournois* and *Pariſis*.

Livre *Tournois*, as above, contains twenty ſols Tournois, and each ſol twelve deniers Tournois.

Livre *Pariſis*, is twenty ſols Pariſis, each ſol Pariſis worth twelve deniers Pariſis, or fifteen deniers Tournois; ſo that a livre Pariſis is equivalent to twenty-five ſols Tournois; the word Pariſis being uſed in oppoſition to Tournois, on account of the rate of money, which was one-fourth higher at Paris than at Tours.

The franc and livre were formerly ſynonimous; but in the coinage of 1795, the franc was made too heavy, and its value was accordingly raiſed $1\frac{1}{4}$ *per cent.*: thus, 80 francs = 81 livres. In 1796, it was ordered that the piece of five francs ſhould paſs for five livres one ſol three deniers Tournois, from which the proportion of the franc to the livre of 100 to $101\frac{1}{4}$ is determined; but the accuracy of this proportion has been queſtioned by writers of the firſt authority, who have calculated it to be as 100 to $101\frac{1}{2}$. See Coins, Exchange, and Money.

For an account of the coin and money of account, both under the old and new ſyſtem of 1795, ſee Money.

There have ſince been pieces of gold ſtruck of twenty ſols value; and under Henry III. in 1575, pieces of ſilver of like value: both the one and the other were called *francs;* and thus the imaginary coin became real. It appears that the Romans had alſo a kind of money, which they called *libra*, or *libella;* which was the tenth part of their denarius; ſo called, becauſe equivalent to an *as*, which at firſt weighed a *libra* or pound of copper. Scaliger adds, that they uſed libra as a term of account, not as a coin: "Libra erat collectio nummorum, non nummus."

Livre *Ouvert*, *Fr.* in *Muſic.* To ſing or play *à livre ouvert*, is equivalent to playing or ſinging *at ſight*, at the opening of a book. All muſicians pique themſelves on being able to perform a muſical compoſition at ſight, without previous ſtudy or practice; but Rouſſeau very juſtly obſerves, that there are few who, in this kind of execution, ſeize the true ſpirit of the author, and who, though they hit the right notes, do not miſtake the expreſſion.

LIUSDAL, in *Geography*, a town of Sweden, in the province of Helſingland; 32 miles W.N.W. of Hudwickſwal.

LIUSNABRUCK, a town of Sweden, in the province of Helſingland; 5 miles S. of Soderhamn.

LIUSNAN, a river of Sweden, which riſes in the mountains of Harjedalen, and diſcharges itſelf into the gulf of Bothnia; 8 miles S. of Soderhamn. N. lat. 61° 15′. E. long. 17°.

LIUSTARNO, an iſland of Sweden, in the Baltic. N. lat. 59° 30′. E. long. 18° 30′.

LIUSTORP, a town of Sweden, in Medelpadia; 15 miles N. of Sundſwall.

LIUSUDBORG, a town of Sweden, in Nericia; 40 miles N. of Orebro.

LIUTPRAND, in *Biography*, an hiſtorical writer of the tenth century, ſaid by ſome authors to have been a Spaniard, by others an Italian. His father was in the confidence of Hugo, king of Italy; and the ſon, while very young, was placed in the court of Berenger II., who obtained the kingdom by diſpoſſeſſing Hugo, and was ſent by him ambaſſador to the Greek emperor, Conſtantine Porphyrogenitus, on account of his intimate acquaintance with the Greek language. Loſing the favour of his own maſter, he was obliged, in 958, to go an exile to Germany, where he compoſed the hiſtory of his own times, which is extant. The fall of Berenger, who was ſtript of his dominions, in 961, by Otho I., reſtored Liutprand to his country; and he was ſoon after conſecrated biſhop of Cremona. In quality of this office, he attended an aſſembly of biſhops at Rome in 963, in oppoſition to the pope, John XII. He was again ſent ambaſſador to the court of Conſtantinople, in the name of Otho, to ſolicit the daughter of the Greek emperor for the ſon of Otho: he was unſucceſsful; and being much hurt at the reception he met with, he ſatirized the pride and ignorance of the court in an account of his embaſſy, annexed to his hiſtory. The time of his death has not been aſcertained; but his ſignature occurs in a ſynod held at Ravenna in 970, under the title of Liuzio, biſhop of Cremona. This hiſtorical work of Liutprand conſiſts of ſix books, of which ſome of the latter chapters are ſuppoſed to have been written by another hand. It has paſſed through ſeveral editions: the laſt is that of Muratori, in his "Scriptores Rerum Ital."

LIUTZIN, in *Geography*, a town of Ruſſia, in the government of Polotſk; 60 miles N.N.W. of Polotſk. N. lat. 56° 25′. E. long. 27° 34′.

LIVY, Titus Livius, in *Biography*, an eminent Roman hiſtorian, is ſuppoſed to have been a native of Padua. He came to Rome in the reign of Auguſtus, and was admitted to the familiarity of ſeveral perſons of rank, and of the emperor himſelf. He made himſelf known by ſome philoſophical dialogues; but his literary reputation was principally built upon his Roman hiſtory, which enjoys a perpetual celebrity: no work of the kind was ever received with greater applauſe. Few particulars of his life are known; yet his fame was ſo univerſally ſpread, even in his life time, that a perſon traverſed Spain, Gaul, and Italy, merely to ſee the man whoſe writings had given him ſuch pleaſure and ſatisfaction in the peruſal. Livy died at Padua in his 67th year, and, according to ſome, on that ſame day Rome was alſo deprived of another of its brighteſt ornaments by the death of Ovid. Livy wrote a letter, addreſſed to his ſon, on the merit of authors, which is greatly commended by Quintilian, who expatiates with great warmth and ardour on the judgment and candour of the writer. His Roman hiſtory was comprehended in 140 books, of which only 35 are extant. It began with the foundation of Rome, and was continued till the death of Druſus in Germany. The merit of this hiſtory is well known, and the high rank which Livy holds among hiſtorians will never be diſputed. His ſtyle is clear and intelligible, laboured without affectation, diffuſive without tedioufneſs, and argumentative without pedantry. His deſcriptions are ſingularly lively and pictureſque; and there are few ſpecimens of oratory ſuperior to that of many of the ſpeeches with which his narratives are copiouſly interſperſed. Of the editions of Livy, thoſe moſt eſteemed are that of Gronovius cum Notis variorum, 3 vols. 8vo. Lugd. B. 1679; of Le Clerc, Amſt. 10 vols.; of Crevier, 6 vols.; of Drakenborch, Amſt. 7 vols. Livy's works have been divided by ſome moderns into 14 decades, each conſiſting of 10 books. The firſt decade comprehends the hiſtory of 460 years. The ſecond decade is loſt, and the third includes the hiſtory of the ſecond Punic war, or a ſpace of about 18 years. In the fourth decade, Livy treats of the wars with Macedonia and Antiochus, which contain 23 years. For the firſt five books of the fifth decade we are indebted to the reſearches of the moderns. They were found at Worms, in the year 1451. Theſe are the remains of Livy's hiſtory. Freinſhemius, with great induſtry and attention, has made an epitome of the Roman hiſtory, which is now incorporated with the remaining books of Livy.

LIW, in *Geography*, a town of the duchy of Warſaw; 40 miles E. of Warſaw.

LIXEME, a town of Pruſſia, in Oberland; 5 miles S.S.W. of Saalfeldt.

LIXIVIOUS, Lixivial, or *Lixiviate*, in *Chemiſtry*, is underſtood of ſalts extracted from burnt vegetables by lotion.

Lixivious ſalts are the fixed ſalts of plants, &c. extracted by calcining the plants, or reducing them to aſhes, and afterwards making a lixivium of thoſe aſhes with water.

Mr. Boyle obſerves, that the difference between lixivious and urinous ſalts conſiſts in this, that the former change the diſſolution of ſublimate in common water into a yellow colour, which the latter do not. See Alkali and Salt.

LIXIVIUM, Ley, or *Lees*, a liquor made by the infuſion of wood-aſhes; or, it denotes any alkaline ſolution, made by lixiviating pearl, or wood, or other aſhes.

What is left after the evaporation of ſuch a liquor is called a lixivious ſalt; ſuch as all thoſe are which are made by incineration.

Lixiviums are of uſe, not only in medicine, but alſo in bleaching, ſugar-works, &c. See Bleaching, Sugar, and Pot-ashes.

Lixivium *Martis*, in *Medicine*, a form of medicine introduced into practice in the London Diſpenſatory. The manner of preparing it is to let the matter remaining in the retort after the ſubliming of the flores martis, in a damp place, where by means of the moiſture of the air it will run into a liquor. See Flores *Martiales*, and Iron.

Lixivium *Saponarium*, *Soap-lees*, *Aqua kali puri*, P. L. 1787; *Liquor potaſſæ*, P. L. 1809; a liquor that has been much uſed in medicine in caſes of the ſtone (ſee Lithontriptic); and when intended for this uſe, it is to be made ſomething leſs ſtrong than for the ſoap-boilers' uſe, and ſhould be prepared in the following manner. Take Ruſſia pot-aſh, and quick-lime, of each an equal quantity; though pure alkaline ſalt requires commonly about twice its weight of quick-lime to render it completely cauſtic, which is known by the ley making no effervescence with acids: throw water on them in ſmall quantities till the lime is ſlaked; then throw on more water, and ſtir the whole together, ſuffering it to ſtand for a day or two, that the ſalt of the aſhes may be diſſolved; after ſome time pour the liquor, filtered through paper, if needful, into another veſſel. A true ſtandard wine-pint of this liquor meaſured with the greateſt exactneſs, ought to weigh juſt ſixteen ounces troy. If it be found on trial to be heavier than this, for every drachm it exceeds that weight, an ounce and a half of water is to be added to each pint: but if it be lighter than this, it muſt be either boiled to this ſtandard, or elſe poured upon freſh lime and aſhes.

The makers of ſoft ſoap with us prepare their lees ſo much ſtronger than this, that to be reduced to this ſtandard, it requires to be diluted with an equal quantity of fair water.

Quick-lime has the property of increaſing conſiderably the cauſticity of all fixed alkalies, by abſorbing their fixable air or gas. See Lime.

This cauſtic ley, evaporated to dryneſs, furniſhes an alkaline ſalt exceedingly acrid, which being melted in a crucible becomes what is called common *cauſtic;* becauſe when it is applied to the ſkin, it makes an eſchar, pierces it, and leaves an ulcer, the ſuppuration of which, when continued, is called an *iſſue*. Cauſtic alkali has not only much greater diſſolving power, but it is alſo much more deliqueſcent, and attracts much more powerfully the moiſture of the air, than ordinary alkali. This inconvenience is avoided by boiling down the ſoap ley only to one-fourth part, and then, while the liquor continues boiling, ſprinkling in, by little and little, ſo much powdered quick-lime as will abſorb it, ſo as to form a kind of paſte.

The *liquor potaſſæ*, or ſolution of potaſs, of the laſt London Pharmacopeia, is prepared by diſſolving a pound of ſubcarbonate of potaſs, *i. e.* the kali præparatum, P. L. 1787, or ſal abſinthii, ſal tartari of P. L. 1745, in two pints of boiling diſtilled water; then adding three quarts of the water to a pound of lime newly prepared: mix the liquors while they are hot, ſtir them together, then ſet by the mixture in a covered veſſel, and, after it has cooled, ſtrain the ſolution through a cotton bag. If any diluted acid, dropped into the ſolution, occaſion the extrication of bubbles of gas, more lime muſt be added, and the mixture ſtrained again. This ſolution is more denſe than water, and, when ſhaken, appears like oil.

Lixivium *Tartari*, the name given in the London Diſpenſatory of 1745 to the liquor called by moſt authors, as in P. L. 1720, *oil of tartar per deliquium;* in P. L. 1787, *aqua kali præparati;* and in P. L. 1809, *liquor potaſſæ ſubcarbonatis*. This is made of tartar, which is to be calcined to a whiteneſs, and then ſet in a damp place, where it will liquify by the moiſture of the air. The liquor thus procured is more pure than if the calcined tartar were diſſolved directly in water.

In the laſt P. L. it is directed to be prepared by diſſolving a pound of ſubcarbonate of potaſs in twelve fluid ounces of diſtilled water, and then ſtraining the ſolution through paper. This ſolution will, in the ordinary ſtate of the ſubcarbonate, amount to nearly 18 ounces in bulk.

LIXURI, in *Geography*, a town of the iſland of Cephalonia; 12 miles W. of Cephalonia.

LIZARD, in *Aſtronomy*. See Lacerta.

Lizard, in *Natural Hiſtory*. Having, in various parts of our work, referred to the article Lacerta, of which, in its proper place, we were diſappointed, we ſhall now, it being the firſt opportunity afforded us after the omiſſion, give an account of the whole genus, including a great variety of animals, which, although they poſſeſs many characters in common, yet exhibit conſiderable differences in their economy and habits, and alſo in their ſtructure and external form.

For the anatomical deſcription of this genus, we refer to the article Reptiles.

The genus lacerta has by ſome naturaliſts been regarded as a diſtinct order, and as ſuch has been divided into ſeveral genera; but following the Linnæan arrangement, we ſhall conſider the ſubject under the diviſions or ſections into which Linnæus ſeparated the genus.

Dr. Shaw has thus enumerated them:

1. Crocodiles, furniſhed with ſtrong ſcales.
2. Guanas, and other lizards, either with ſerrated or carinated backs and tails.
3. Cordyles, with denticulated, and ſometimes ſpiny ſcales, either on the body or tail, or both.
4. Lizards proper, ſmooth, and the greater number furniſhed with broad ſquare ſcales, or plates on the abdomen.
5. Chameleons, with granulated ſkin, large head, long miſſile tongue, and cylindric tail.
6. Geckos, with granulated or tuberculated ſkin, and lobated feet, with the toes lamellated beneath.
7. Scinks, with ſmooth, fiſh-like ſcales.
8. Salamanders, newts, or efts, with ſoft ſkins, ſome of which are water-lizards.
9. Snake-lizards, with extremely long bodies, very ſhort legs, and minute feet.

This is an active tribe, and, with the exception of the aquatic animals, feeds on inſects: the crocodiles have both jaws moveable, and the largeſt mouth of all animals: their body is covered with calloſities: the chameleons have a prehenſile tail; ſit on trees; walk ſlowly and irregularly; have no teeth; eyes large, fixed in a wrinkled ſocket; tongue very long, worm-ſhaped, with which they draw in flies; head angular, covered with very thin lucid tubercles or ſcales.

The foregoing diviſions, it is admitted, neither are nor can be perfectly preciſe, ſince ſpecies occur which may, with nearly equal propriety, be referred to either of the neighbouring ſections: on this account naturaliſts have not been agreed as to the exact number of ſpecies in each ſection, nor even as to the number of ſections themſelves. Dr. Shaw, as we have ſeen above, has ſeparated the genus into nine ſections; he has been followed by many other reſpectable writers, but in the laſt edition of Gmelin, as given by Dr. Turton, the genus is divided into eleven ſections, which ſhall be given in their order.

Section A. Tail two-edged, divided into ſegments; tongue very ſhort.

Species.

Crocodilus, or Crocodile of the Nile; has a mailed head; nape carinate, tail above with two lateral creſts.

This animal, as its name imports, is chiefly found in the river Nile, or on it's banks. It ſometimes arrives at a very great ſize: the common ſize of a full grown crocodile is from 18 to 25 feet long, though ſome have been ſeen that meaſure full forty feet in length. The colour of the upper part is a blackiſh-brown, but beneath it is of a yellowiſh-white. The upper parts of the legs and ſides are varied with deep yellow, and in ſome parts tinged with green. The opening of the mouth is of vaſt extent, and both jaws are furniſhed with numerous ſharp-pointed teeth; thoſe in the middle part of the jaw being largeſt, and reſembling the canine teeth of viviparous animals. The external openings of the ears are placed on the top of the head, above the eyes, and the eyes themſelves are furniſhed with a nictitating membrane, ſimilar to that of birds. The legs are ſhort, ſtrong, and muſcular. The tail is long, compreſſed on the ſides, and furniſhed above with an upright proceſs, formed by the gradual approach of two elevated creſts, which proceed from the lower part of the back. The upper part of the body of the crocodile is covered with a ſtrong armour, which in its ſtructure exhibits the appearance of the moſt curious carved work, and is indeed a fine piece of mechaniſm. The crocodile depoſits its eggs in the ſand or mud on the banks of the rivers which it inhabits, and as ſoon as the young are hatched, they proceed to the water. The crocodile is a native of Aſia and Africa, but it ſeems more common in the latter than in the former country. It inhabits only large rivers, and lives chiefly on fiſh, but being extremely voracious, it ſeizes any other animal that comes within its reach. The crocodile has long been regarded as one of the moſt formidable animals of the countries in which it is found, but ſome late travellers ſeem to have entertained a leſs formidable opinion of them. M. Denon, ſpeaking of the French army in Egypt, ſays that the ſoldiers and himſelf bathed daily in the Nile, and yet they were never once attacked by them, nor did they ever meet with a ſingle crocodile at a diſtance from the water. Hence he inferred that they find in the river a ſufficient quantity of eaſily procurable food, which they digeſt ſlowly, being, like the lizard and ſerpent, cold blooded, and of an inactive ſtomach. "Beſides," ſays the traveller, "having in the Egyptian part of the Nile no enemies but each other and man, they would be truly formidable, if, covered as they are with an almoſt impenetrable defenſive armour, they were ſkilful and alert in making uſe of thoſe means which nature has given them for attack." He farther adds, that they ſaw three crocodiles, one of which was nearly twenty-five feet in length; they were all aſleep, ſo that they could approach them within about twenty yards, and had an opportunity of diſtinguiſhing them very accurately. He ſays, that in that poſition they reſembled diſmounted cannon: he fired on one, the ball ſtruck him and rebounded from his ſcales. He made a leap of ten feet, and dived into the river.

In the large rivers of Africa, and in certain parts of thoſe rivers, they may be ſeen in vaſt ſhoals ſwimming together, where they exhibit the appearance of floating timber. A variety of the common crocodile has been found in the river Senegal, it has a longer ſnout, and is almoſt entirely black. It is very ſwift, voracious, and of amazing ſtrength; it roars hideouſly; devours every thing that comes in its way; ſwallows ſtones to prevent hunger, and cannot be killed by a muſket ball unleſs ſtruck on the belly: it ſeldom moves but in a ſtraight line, and may accordingly be avoided: the female lays her eggs in the ſand, which are not much larger than thoſe of a gooſe.

Gangetica, or Gangetic crocodile. This animal has long, roundiſh, or ſub-cylindric jaws; its tail on the upper ſide has two creſts running into one.

This ſpecies is found in the Ganges, where it is nearly equal in ſize to the common crocodile. In this the ſtructure of the ſnout is very remarkable, it being nearly three times as long as the head. The eyes are extremely prominent, and it is ſaid they are ſo conſtructed, that they may be raiſed above the water, when the reſt of the body is under the ſurface, by which the animal is enabled to ſee its prey either on the ſurface of the water, or on the banks of rivers. In the general form and colour of the body and limbs, this ſpecies reſembles the common crocodile. In the Britiſh Muſæum is a ſpecimen of this creature, meaſuring eighteen feet in length.

Alligator. The head of this animal is flat, imbricate; nape naked; tail above with two rough lateral lines.

It inhabits the middle parts of America, is leſs than a crocodile, but reſembles it in habits and voracity. The largeſt in ſize, and the greateſt numbers of alligators, inhabit the torrid zone, nevertheleſs the continent ten degrees more north abounds with them, particularly as far as the river Neus in North Carolina. In the latitude 33°, which anſwers to the northernmoſt parts of Africa, where they are likewiſe found, they frequent not only ſalt rivers near the ſea, but ſtreams of freſh water in the upper parts of the country, and in lakes of ſalt and freſh waters, on the banks of which they lie lurking among the reeds to ſurpriſe cattle and other animals. They are found in Jamaica, and many parts of the continent, full 20 feet in length. But we are told they cannot be more formidable in their aſpect than terrible in their nature, ſparing neither man nor beaſt which come within their reach, pulling them under water and drowning them, in order that they may with greater facility, and without a ſtruggle or reſiſtance, devour them. They ſubſiſt chiefly on fiſh, but as Providence, for the preſervation, or to prevent the extinction of defenceleſs creatures, has in many inſtances reſtrained the devouring appetites of voracious animals, by ſome certain impediments; ſo this deſtructive monſter can proceed only in a ſtraight forward direction, and is conſequently diſabled from turning with that agility requiſite to catch his prey by purſuit; therefore alligators do it by ſurpriſe in the water, as well as by land: they have the power of deceiving and decoying their prey, by a ſagacity peculiar to themſelves, as well as by the outer form and colour of their body, which on land reſembles a log or tree, and in the water lies floating on the ſurface, and has the like appearance, by which, and their ſilent artifice, fiſh, fowl, and turtle, are lured into their graſp, and ſuddenly catched and devoured. Carnivorous animals get their food with more difficulty, and leſs certainty than thoſe which ſubſiſt on vegetable ſubſtances, and are frequently obliged to faſt long, which a ſlow digeſtion enables them to endure. Reptiles particularly, by ſwallowing whole what they eat, can live long without food. Alligators ſwallow ſtones and wood, to diſtend the ſtomach and prevent its contraction by emptineſs. They lay a great number of eggs at one time on ſandy banks of rivers and lakes, which are hatched by the heat of the ſun, without any care of the parent. The young, as ſoon as they are diſengaged from the ſhell, run to the water by a natural inſtinct and ſhift for themſelves, and while young they ſerve as a prey not only to ravenous fiſh of other tribes, but to their own ſpecies. In South Carolina they are numerous, but ſmaller than thoſe towards the equator, but they attack men and cattle, and are great devourers of the race of ſwine. In Carolina they lie torpid during the winter in caverns and hollows in the banks of the rivers, and at their coming out in the ſpring make a hideous bellowing noiſe. According to Cateſby, in his hiſtory of Carolina, ſome parts of alligators are reckoned very delicious food by the Indians. They depoſit their eggs at two or three different periods, and more than twenty of them at each laying. They have been obſerved to raiſe a ſmall hillock near the banks of the river, and after hollowing it out in the middle, to collect a quantity of leaves and other vegetable matters, in which they depoſit their eggs. Both the alligator and crocodile are ſuppoſed to be long lived animals. It has been thought the crocodile, or ſome of the ſpecies, was the leviathan mentioned in the book of Job, chiefly, perhaps, becauſe the deſcription of this monſter does not ſufficiently correſpond with the general ſtructure of the whale; nevertheleſs, the leviathan there mentioned will correſpond full as little with any of the ſpecies of the crocodile now known as with the whale, and it is more probable, that, like the mammoth, the leviathan of the ſcriptures is not now to be found on the face of the earth.

Section B.—The animals of this ſection have the body covered with carinate ſcales.

Species.

CAUDIVERBERA, or flat-tailed lizard, is found in Peru and Chili, and is about twelve or fifteen inches long. The tail is depreſſed, flat, wing-cleft; feet palmate. The body is inclining to blue; ſcales very minute; head convex, oblong; eyes very large, yellow; noſtrils wide, with a fleſhy edge; mouth large, teeth minute, hooked in a double ſeries; tongue thick, broad, red; chin with a dilatable pouch; creſt running down the back from the front to the tip of the tail, undulate at the edge; feet five-toed, with a cartilage inſtead of nails.

DRACÆNA, or large long-tailed lizard, with a ſmooth body, and tail denticulated along the upper part. The body is of a deep cheſnut-colour; the ſcales are very minute; the legs teſſellate, with ſaffron and white. It inhabits America, and has been named the large American cordylus, and has ſometimes been confounded with the caudiverbera juſt noticed.

It is a native of ſeveral parts of South America, and of ſome of the Indian iſlands, and is regarded, in ſome countries in which it is found, as a great delicacy. The head is ſmall, and rather elegantly formed, the ſnout tapering in ſuch a manner as to bear a reſemblance to that of an Italian grey-hound; the teeth are ſmall and numerous, and the tongue forked; the proportions of the neck and limbs are elegant, though ſtrong; and the body is moderately thick; the tail is of great length. The whole animal is ſmooth, or deſtitute of prominences on the ſkin, which is covered with ſmall, ovate, and, in ſome parts, ſlightly ſubquadrate ſcales, largeſt on the outſide of the limbs, the back, and the abdomen; along the upper edge of the tail runs a continued ſeries of ſhort triangular denticulations; the feet are moderately ſtrong, and the toes are armed with ſharp crooked claws.

Dr. Shaw mentions a variety, of which there was a ſpecimen in the Leverian Muſæum, which differs in being of a pale brown colour, variegated on the body and tail by ſeveral deep-brown tranſverſe bands, among which, as alſo on the abdomen and limbs, are interſperſed many ſmaller variegations, and ſpots of a ſimilar colour.

BIMACULATA, or Pennſylvanian lizard, has a tail carinate, toothed, twice as long as the body, all the toes, of which there are five on each foot, are lobate. The colour of its body is greeniſh-blue, moſtly ſpotted with black; the ſhoulders with two large ſpots. It is found in the woods of St. Euſtatius and Pennſylvania, and lives in holes, gutters, and hollow trees; makes a hiſſing noiſe, and depoſits its eggs in the earth.

MONITOR, or monitor lizard, is one of the largeſt of the lizard tribe; it meaſures ſometimes from four to five feet. Its colour is black; tail very long, compreſſed, carinated; body marked with tranſverſe rows of white, ocellated.

This is a very beautiful animal. The head is ſmall; the ſnout gradually tapers; the limbs are ſlender; and the tail, which is laterally compreſſed, gradually decreaſes towards the extremity. As a whole, the form is ſlender and elegant; though the colours are ſimple, they are ſo diſpoſed as to produce an agreeable effect. It is a native of South America, inhabiting woody and marſhy places. If credit may be given to reports of authors, who pretend to have ſtudied its habits and characters with much accuracy, its diſpoſition is as gentle as its appearance is beautiful. It has even gained the title of monitor ſalvaguarda, &c. from its pretended attachment to the human race: it has been confidently affirmed, that it warns mankind of the approach of the alligator by a loud and ſhrill whiſtle.

There is a variety of this animal mentioned by White, in his "Journal of a Voyage to New South Wales;" but in Gmelin's edition of the "Syſtema Naturæ," it is given as a diſtinct ſpecies, under the name of

VARIA, or variegated lizard. Though there is a great reſemblance between this and the monitor; yet there are certain points of difference in its colour, and variegations that will juſtify its introduction as a ſeparate ſpecies. The tail is long, carinate; body blackiſh, tranſverſely variegated with yellow ſpots and marks.

It is found in New Holland. The markings on the body, inſtead of the general ocellated pattern of the preceding, conſiſt of rounded, or ſlightly ſubangular ſpots and variegations: the limbs, as in the monitor lizard, are marked with numerous bands and ſpots, and the tail is banded; the claws are very large and ſtrong.

BICARINATA, or bicarinated lizard, has a tail of moderate length; four rows of ſtrong carinated ſcales on the back. The head is ſmall; the mouth very wide in proportion, and the ſnout ſomewhat ſharp. It is of a reddiſh-brown colour, tinged in ſome parts with various ſhades of green.

In its general habit, this ſpecies bears a reſemblance to a ſmall crocodile, on account of the hard tuberculated and carinated ſcales, on the upper parts of the body, two rows of which are more prominent than the reſt, and extend from the upper part of the back to the tail, where they coaleſce and form a ſerrated creſt to the extremity. It is a native of South America, where it is ſometimes uſed as food, and its eggs are highly eſteemed. Its haunts are woody and marſhy regions: it is fond of water; and one kept ſome time by M. de la Borde, often continued in it for ſeveral hours together, hiding itſelf when diſturbed or affrighted, but it ſeemed delighted in coming out and baſking in the direct and ſtrong rays of the ſun.

A lizard, known under the name of *ignaruca*, a native of Brazil, is regarded as a variety of the ſpecies juſt deſcribed, differing only in colour, which is darker, and the claws, which are ſhorter, but, like it, there is ſome reſemblance between it and the crocodile: it readily climbs trees.

CORDYLUS, or Cordyle lizard, has a ſmooth body, ſhort tail that is verticillated with denticulated ſcales. This ſpecies is ſometimes blue, and ſometimes of a livid-brown, and the total length is not above ten or eleven inches. The ſcales which cover the body are of an oblong form, and the tail is verticillated with rows of large ſcales.

Section C. Back and tail, or the whole body, covered with denticulate or ſharp-pointed ſcales.

Species.

PELLUMA, or Pelluma lizard, has a long tail, and verticillated with rhomboidal ſcales. It is about two feet in its total length, and is diſtinguiſhed on the upper parts of its body by a beautiful variety of green, yellow, blue, and black colours. The under parts of the body are of a gloſſy yellowiſh-green: it is a native of Chili, and lives under ground; the inhabitants of that country make its ſkin into pouches. Its feet are five-toed, and its claws very ſtrong.

STELLIO, or rough lizard, has a verticillated tail, with denticulated ſcales: the body and head are muricated.

This ſpecies, as its Engliſh name implies, is remarkable for the unuſually rough appearance of its whole upper ſurface; both body, limbs, and tail being covered with pointed ſcales, projecting here and there to a conſiderable diſtance beyond the ſurface. The general colour of the animal is a pale blueiſh-brown, with a few deeper and lighter tranſverſe variegations. It is not above eight or nine inches in length. It is a native of many parts of Africa. Dr. Shaw, in ſpeaking of this ſpecies, ſays, "it may be obſerved that the lizard, which was probably termed *Stellio* by the ancients, from its being marked with ſpots reſembling ſtars, ſeems at preſent unknown. It is, however, obſervable, that in one of Seba's plates a ſpecies occurs, which is actually marked with well-defined or regular ſtar-ſhaped ſpots." Some naturaliſts conſider the lizards called geckos as the true *ſtelliones*.

MAURITANICA, or Mooriſh lizard, is characterized by a ſubverticillate tail, muricate, ſhort, ſmooth at the tip, body above muricate, toes unarmed, lamellate beneath.

This is one variety: the ſecond is diſtinguiſhed by a verticillate tail; and the third by having a prickly body. It is found in Mauritania, and in ſome parts of India. The body is lurid, the upper part has protuberances, the lower is ſmooth; ſcales are very minute; tail ſhorter than the body, from the baſe to the middle rough, with ſix rows of ſpines, thence to the tip ſmooth.

AZUREA, Azure lizard. Tail verticillate, ſhort with mucronate ſcales.

This is the *elegantiſſima* of Seba. The colour, in its natural ſtate, ſeems to be an elegant pale blue, faſciated on the body and tail with ſeveral tranſverſe, and alternate bands either of black or very deep blue; but this is ſaid to be moſt conſpicuous in the ſmaller ſpecimens or varieties. It is ſometimes only a few inches long. The larger variety has a deep cheſnut band on the ſhoulders. The ſmaller variety is a native of ſome parts of Africa; the larger of South America.

ANGULATA, or Angulated lizard, has a long and hexagonal tail, and is furniſhed with carinated and mucronated ſcales. This is a ſmall ſpecies, having a tail longer than the body. The colour is of a duſky brown. Beneath the throat there are two rounded ſcales. The tail is longer than the body, and ſtrongly marked with longitudinal ridges. It is a native of America.

ORBICULARIS, or Orbicular lizard, has a brown body; the tail is ſhort, ſcales muricated. Both body and tail are round. The colour is of a duſky brown, variegated with different ſhades; the body is large, and in ſome reſpects it reſembles a toad. It is a rare ſpecies, and is a native of South America, particularly in New Spain.

BASILISCUS; Baſiliſk lizard. Tail round; dorſal fin radiate; hind-head creſted. The baſiliſk is about eighteen inches long, of a pale aſh brown colour, with ſome darker variegations about the upper part of the body. In the young animal, the dorſal or caudal proceſs, and the pointed occipital creſt, are leſs diſtinct.

The baſiliſk is chiefly a native of South America. It reſides principally among trees, and its food is inſects. It is active, and by means of its dorſal creſt or fin, it is enabled to ſpring from tree to tree. It can ſwim with great eaſe. It has a very formidable appearance, but is quite harmleſs. In the poetical deſcriptions of the ancients, it was conſidered to be the moſt malignant of all poiſonous animals, even its look was regarded as fatal. The terrific glance of the baſiliſk in the African deſerts, according to Lucan, obliged the reſt of the poiſonous tribe to keep at a diſtance.

PRINCIPALIS; Smooth-creſted lizard. The tail of the ſpecies is ſubcarinate; creſt on the throat very entire, back ſmooth. It is of a ſlender form, and ſmall, rarely exceeding eight or nine inches in length, including both body and tail. The colour is blue, the head ſmall, and the ſnout taper. It is a native of South America.

PLATURA; Broad-mailed lizard. Colour grey-brown, paler beneath; body rough; tail depreſſed, lanceolated, and ſpiny on the margin. This ſpecies is from four to ſix inches long; it is diſtinguiſhed by the ſingular form of its tail. The feet are pentadactylous; the toes ſlender, and the claws curved. It is found in New Holland.

Section D. Back ciliate, toothed or creſted; head covered with calloſities.

Species.

IGUANA; Common or great American Guana. This ſpecies has a long round tail; back ſerrated; the throat creſt denticulated. This, of all the lizard tribe, is of the moſt peculiar form, and grows to a conſiderable ſize. It is ſometimes three, four, or five feet long. The general colour is green, ſhaded with brown. The back is ſtrongly ſerrated, which, as well as the denticulations of the pouch at the throat, gives it a formidable appearance.

It is a native of the Weſt Indies, and ſome parts of the continent of America. It frequents rocky and woody places, and feeds chiefly on inſects and vegetables. It is eaſily tamed, and follows the human race like a dog; it is caught by a nooſe thrown over its head; the fleſh is reckoned a great delicacy: the general colour is green, but variouſly tinged in various animals: it has the power of inflating the throat pouch to a very large ſize.

According to Cateſby the animals of this ſpecies are of various ſizes, from two to five feet in length; their mouths are furniſhed with exceedingly ſmall teeth, but their jaw is armed with a long beak, with which they bite with great ſtrength. They inhabit warm countries only, and are rarely met with any where north or ſouth of the tropics. Many of the Bahama iſlands abound with them, where they neſtle in hollow trees and rocks. Guanas make a conſiderable part of the ſubſiſtence of the inhabitants of the Bahama iſlands, for which purpoſe they viſit many remote iſlands in their ſloops to catch them, which they do by dogs trained for the purpoſe. Guanas feed on vegetables and fruit, particularly on a kind of fungus growing at the roots of trees, and on the fruits of the anonas. Their fleſh is eaſy of digeſtion, but is thought not to agree with conſtitutions labouring under a particular diſeaſe.

Though guanas are not amphibious, they are ſaid to keep under water above an hour. When they ſwim they make no uſe of their feet, but clap them cloſe to their body, and guide themſelves with their tails. They are ſo impatient of cold, that they rarely appear out of their holes except when the ſun ſhines ſtrongly.

The *horned* guana is a variety of the iguana, and is nearly the ſame in ſize and general proportions; the back is ſerrated, and the form of the ſcales is the ſame. It wants, however, the throat pouch, and there are in front of the head, between the eyes and noſtrils, large ſcaly tubercles, behind which there is a bony conical proceſs, which is covered with a ſingle ſcale. It is a native of St. Domingo, where it is common.

Calotes; Galeot lizard. Tail long and round; back dentated on the fore part, and the head on the hind part.

The animals of this ſpecies ſeldom exceed a foot and a half in length, from the tip of the noſe to the extremity of the tail, but in other reſpects the calotes reſembles the common guana. It wants the pouch, and in its place there is only a ſlight enlargement of the throat: the colour is commonly of an elegant bright blue, variegated with broad, irregular, white, tranſverſe bands on each ſide of the body and tail. The limbs are ſlender, and this is particularly the caſe with the toes. It is a native of the warmer regions of Africa, Aſia, and many of the Indian iſlands. It is very common in Ceylon. It is ſaid to be found in Spain, where it wanders about the tops of houſes in ſearch of ſpiders.

There is a variety, of which the body above is livid, and beneath green: and a ſecond, the neck of which is covered with broad obtuſe prickles.

Superciliosa; Fringed lizard. Tail carinated; back and eye-brows ciliated, with upright lanceolated ſcales. It inhabits South America and India.

The general appearance of this ſpecies bears ſome reſemblance to the guana, and ſtill more to the variety deſcribed as the horned guana, in having the appearance of a pair of ſharp-pointed horn-like proceſſes above and beyond each eye; between theſe are placed ſome aculeated ſcales.

Scutata; Shielded lizard. Tail ſub-compreſſed, moderately long; dorſal ſuture toothed; hind-head with two ſharp ſcales. It inhabits Aſia. This ſpecies is diſtinguiſhed from the fringed lizard by having a proportionably larger head, and a row of ſcales more elevated than the reſt, paſſing over each eye; and from theſe a ridge is continued towards the back, in form of a denticulated creſt to the beginning of the tail. The body is covered with ſmall acuminated ſcales; the limbs and tail with larger ones. This is a native of Ceylon.

Amboinensis; the Amboina lizard. Tail compreſſed, long, with a radiate fin; dorſal ſuture toothed. This ſpecies, which ſometimes grows to the length of three feet, is diſtinguiſhed by the ſingularity of its appearance, and the beauty of its colours. The head and neck are green, and variegated with white tranſverſe undulations. The back and tail are brown, with a ſhade of purple. The ſides and belly are greyiſh, or pale brown, the head is tuberculated above, and covered with roundiſh ſcales; the mouth is wide, and the teeth are ſharp and numerous.

It is a native of the Eaſt Indies, but is found moſt frequently in the iſland of Amboina, frequenting the neighbourhood of rivers and other freſh waters. It is often ſeen on the banks of riſing grounds, and on low ſhrubs which grow near the water. Whenever it is diſturbed by the approach of men or other animals, it plunges into the neareſt water and conceals itſelf beneath the rocks, or ſtones under the banks. It may be eaſily taken, as it does not attempt to defend itſelf, but ſeems, in ſome meaſure, ſtupified. Like other ſpecies of this numerous tribe, it depoſits its eggs in the ſand, on the banks of the rivers which it frequents. The eggs, while in the body of the animal, are diſpoſed in two long groups or cluſters, and are of a yellow colour; but when excluded, they are white and oblong.

This lizard appears in ſome degree to form a connecting link between the guana and the baſiliſk. The male and female differ conſiderably in ſize and in the diſtribution of their colours; the female being of a more obſcure tinge than the male, and having but little appearance of the creſt or proceſs on the tail. It has been diſſected, and a ſmall triangular heart found within it: an oblong liver, with a round gall-bladder; ſmall reddiſh lungs, ſlightly tinged with lead-colour; a narrow, whitiſh ſtomach, coated, or enveloped in fat, and large inteſtines, in which were diſcovered the berries and ſeeds of certain aquatic ſhrubs, together with ſome ſmall ſemi-tranſparent pebbles, and a kind of worms not unlike millepedes. There was a fine ſpecimen of this ſpecies in the Muſeum of the late Mr. John Hunter.

Agama; American galeot. Tail long, round; the upper part of the neck, and the back of the head, are aculeated; ſcales of the hind head reverſed. This ſpecies reſembles, in ſome reſpects, the calotes: but it wants the ſtrong ſerratures on the back, inſtead of which it has only a ſmall denticulated carina. The head is proportionally larger, and on the back part it is furniſhed with ſharp-pointed ſcales, ſome of which are reverſed at the extremities. The colour is browniſh, and variouſly clouded. In the male, the creſt on the back is compoſed of longer ſpines, and extends to the lower part. It is found in different parts of South America and in the Weſt Indian iſlands.

There is a variety of this ſpecies named the muricated lizard. The tail is long, round; body greyiſh; ſcales carinated and ſharp pointed. This lizard meaſures a foot or more in length. The want of the reverſe ſcales on the back part of the head conſtitutes the principal difference between this and the calotes. It is found in New South Wales.

Umbra; Clouded lizard. Tail round, long; nape ſubcreſted; hind-head callous; back ſtriated. This is found in the ſouthern parts of America: the body is clouded; ſcales keeled, and daggered at the tip, head more obtuſe and round than others of its tribe: the *callus* on the hind part of the head is large and naked: under the throat is a deep fold.

Marmorea; Marbled lizard. Tail round, long; throat ſubcreſted, dentate on the fore-part; back ſmooth. It is found in America, and alſo in Spain. Its body is compreſſed; tail ſtreaked, and the claws are black above.

Cristata; Creſted lizard. Tail lanced, ſhort, pinnate; back creſted; body porous, naked. It is of a reddiſh-brown with lead-colour ſpots; creſt reaching from the head to the tail; the head is very thick, obtuſe; ſnout broad; feet cleft; four toes on the front feet and five on the hinder ones; tail bordered on each ſide with a membrane.

Section E. Body naked; feet unarmed; fore-feet four-toed.

Species.

Americana. Tail lanceolate, middle-ſized; back fringed; belly ſpotted with yellow; it is only about four or five inches long, and is found in America. The fore-part of the head is rounded; ſnout broad; body duſky blueiſh, beneath yellow ſpotted with black, ſides pale ochre;

legs without blueiſh, within yellow; a fringe extending from the head to the tip of the tail.

Palustris; Warted newt. Body blackiſh; ſides ſpeckled with white; belly orange, with irregular black ſpots. This ſpecies is ſmall, and bears a conſiderable reſemblance to the ſalamander. It is from five to ſix inches in length. The tail is flat, with thin ſharp edges, and terminating in a point; on each ſide of it in the male there is a ſilvery white broad band, accompanied with a blueiſh tinge. This ſtripe and the dorſal creſt are ſometimes wanting in the female.

It is found in many parts of Europe, but is rarely ſeen in Britain. It frequents ſtagnant waters in cool and ſhady places, and lives entirely on inſects. It is ſaid to be entirely harmleſs with regard to larger animals, but that a fluid is exuded from its ſkin which ſeems to act as a poiſon on ſmall animals.

Lacustris; Fenny-newt. Of this ſpecies there are ſeveral varieties. 1. Black; tail lanceolate, middle-ſized. 2. Much larger; ſpotted with black. 3. Variegated white and yellow, and ſpotted with black. 4. Tuberculate; chin ſpeckled; belly ſpotted; tip of the tail red. 5. Tuberculate; belly ſaffron colour. 6. Head round; black ſpotted with pale yellow. 7. Black with whitiſh bands. 8. Black; beneath dotted with white. This ſpecies, which is found in many parts of the world, is very deſtructive of fiſh.

Aquatica; Water-newt. Tail roundiſh, middle-ſized; there are likewiſe varieties; brown or yellowiſh; and one with a dorſal line dotted with white and black; the firſt is found in many parts of Europe; the ſecond inhabits France; and the third in Germany.

It lives in pools, ditches, and ſtagnant waters, and is killed in three minutes if ſalt be ſprinkled upon it. The body is ſpongy, blackiſh dotted with black; chin rough; back ſubcreſted; tail ſmooth, ſpeckled with a longitudinal white ſtripe on each ſide.

The general length of this ſpecies is from three to four inches. The male is readily diſtinguiſhed from the female by a conſpicuous dorſal creſt, which is more elevated, and more regularly ſinuated than that of the paluſtris. The broad creſt is very tranſparent, and when examined by a magnifying-glaſs ſhews the ramifications of the blood-veſſels and the circulation of the blood. In the female the dorſal creſt is nearly wanting. The fore-feet are tetradactylous; but the hind-feet have five toes, and in all, the claws are wanting; but with regard to colour, the breadth of the tail, and that of the toes, water-newts differ at different ſeaſons of the year, in different ſtates of the weather, and ſometimes a conſiderable variation is obſerved even in the courſe of the ſame day.

This ſpecies is very common in ſtagnant waters. It breeds early in the ſpring, and depoſits ſmall oblong ſtrings or cluſters of ſpawn. The ova are of a kidney ſhape, and the larvæ are ready formed, and may be ſeen active and ſporting before they leave the gluten. They extricate themſelves in about ten days, and when they are firſt excluded, the branchial fins are diſtinctly ſeen, and ſoon after their fore-legs appear. In a fortnight the hind-legs are viſible, and in about four or five months the branchial fins become obliterated, and the animal aſſumes a perfect form. In the larva ſtate, the animal has the appearance of a ſmall fiſh. It caſts its ſkin, which may be found floating on the waters which it frequents, and is ſometimes ſo perfect as to repreſent the whole form of the complete animal. The reproductive power of this ſpecies of lizard has been noticed as a very ſtriking circumſtance in natural hiſtory. They have been known to have their legs, tails, and even their eyes reſtored after they have been deſtroyed. It has alſo been aſcertained that water-newts have been completely encloſed in a maſs of ſolid ice, in which they have remained ſeveral weeks, and yet upon a thaw the little animals have been reſtored to their former health and vigour. We may mention in connection with this a ſpecies deſcribed by Dr. Shaw, denominated the

Leverian Water newt; of which there was a good ſpecimen in the Leverian muſeum. The total length of this is 17½ inches, and its tail is about ſix or ſeven inches of it. The head is flattened, the mouth moderately wide, and the upper jaw is furniſhed in front with two concentric rows of numerous, ſmall, briſtly teeth. The under jaw has only a ſingle row. The eyes are ſmall, round, ſituated on each ſide of the front of the head, ſo that they are remote from each other. The colour is pale brown, marked with darker variegations. The legs are about an inch in length, and they are all furniſhed, along their whole length behind with a dilated ſkin or creſt. The tail is like that of a common water-newt, but ſhorter and not ſo deeply finned.

Salamandra; Salamander. The ſpecific character of this animal is, colour black, ſpotted with golden yellow; tail round, and of moderate length. Of this ſpecies there are, beſides the one deſcribed, ſome entirely black; ſome brown; ſome white; and ſome ſmall, brown; with a tail in ſome degree compreſſed. The ſalamander, ſo long the ſubject of popular error, and of which ſo many idle tales have been recited by the more ancient naturaliſts, is an inhabitant of many parts of Germany, Italy, France, &c. but has not been diſcovered in England. It delights in moiſt and ſhady places, and during winter conceals itſelf in receſſes under ground, in the cavities of old walls, or about the roots of old trees. It is eaſily diſtinguiſhable by its fine colours; being of a deep ſhining black, variegated with large, irregular patches of bright orange-yellow; which on each ſide the back are commonly ſo diſpoſed, as to form a pair of interrupted longitudinal ſtripes; on each ſide of the back of the head is ſituated a pair of large tubercles, which are in reality the parotid glands, that are protuberant not only in this and other ſpecies of the Lacerta genus, but in a remarkable manner in the Rana or frog tribe. See Rana.

Theſe parts, as well as the back and ſides of the body, are beſet in the ſalamander with ſeveral large open pores, through which a peculiar fluid is exuded, ſerving to lubricate the ſkin, and which, on any ſudden irritation, is ſecreted in a more ſudden and copious manner under the form of a white gluten of a ſlightly acrimonious nature; and from the readineſs with which the animal, when diſturbed, appears to evacuate it, has ariſen the long continued popular error of the ſalamanders being enabled to live uninjured in the fire, which it has been ſuppoſed capable of extinguiſhing by its natural coldneſs and moiſture; the real fact is this, that like the other cold and glutinous animals, as ſnails, frogs, &c. it is not quite ſo inſtantaneouſly deſtroyed by the force of fire as an animal of a drier nature would be. The general length of the ſalamander is about ſeven inches, though it ſometimes arrives at a much larger ſize. It lives principally on inſects, ſmall ſnails, &c.; its tongue is not by any means formed to catch theſe in a ſudden manner, being ſhort, broad, and in ſome degree confined, ſo as not to be darted out with celerity. It is capable of living in water as well as on the land, and is found occaſionally in ſtagnant pools. Its pace is ſlow, and its habits torpid. The ſalamander is viviparous, and the young are produced perfectly formed, in the ſame way as the viper. It is ſaid to retire into the water to depoſit its young, the number of which at one birth amounts to 30 or 40; when they are firſt excluded, they are furniſhed with branchial-fins on each ſide the neck; theſe are but temporary organs, and are afterwards obliterated like thoſe of the tadpole.

It has been thought that the ſalamander was a venomous animal, and that its poiſon is of ſo malignant a nature, as ſcarcely to admit of any remedy. Later obſervations and experiments have aſcertained that it is perfectly innocent, and although the fluid ſecreted from the ſkin may be noxious to ſmaller animals, it is incapable of inflicting either wound or poiſon on any large animal.

Strumosa; Strumous lizard. Tail round, long; breaſt gibbous, projecting forward. This is of a ſmall ſize, has no ſerratures, but is furniſhed with a large flat creſt at the throat, of a pale red colour; the other parts of the animal are of a pale blueiſh-grey, with ſome ſlight ſhades of a more duſky hue. The limbs are ſlender. It is a native of South America.

Vittata; Forked lizard. The tail of this ſpecies is round, long; body brown with a white dorſal fillet, forked over the head. It inhabits India; it does not exceed ſix or ſeven inches in length; the head is large in proportion to the body, the toes are lamellated beneath; terminated by curved claws. The upper ſurface is covered with extremely ſmall tubercles, which are ſo minute as ſcarcely to be perceptible.

Turcica; the Turkiſh lizard. Tail ſubverticillate, middle-ſized; body grey, and a little warty. It inhabits the Eaſt. Its body is duſted with brown ſpots, unequal, and as if ſprinkled with ſcarcely viſible warts; the tail is about the length of the body.

Rapicauda; Turnip-tailed lizard. Tail turbinate; ears concave. This ſpecies is found in ſeveral of the American iſlands; the body is white, ſpotted with brown; warts ſmall, thickly ſprinkled; claws hollowed in the middle underneath.

Gecko; Common Gecko lizard. Tail round, middle-ſized; toes a little clawed; ears concave. This animal is ſaid to have received its name from the peculiar ſound of its voice, which bears a reſemblance to that word when uttered in a ſhrill tone. It is twelve or fourteen inches long, and is accordingly ranked among the middle-ſized animals of the lizard tribe; but it is thicker and ſtronger than the greater part of lizards. Its head is flattiſh, ſomewhat triangular, and large, with a covering of minute ſcales; its mouth is wide, eyes large, teeth ſmall, and its tongue is broad and flat. The uſual colour of the gecko is brown, with ſome irregular duſky or blueiſh variegations, but this colour becomes more brilliant in warmer regions.

It inhabits India, Arabia, Egypt, and the warmer parts of Europe; it frequents houſes in ſummer, but is ſeldom ſeen in the winter; makes a noiſe like a weaſel; is tame, and when frighted will run into houſes for ſhelter; it emits a poiſonous fluid from the lamellæ beneath its feet, which, if ſmeared over fruit, or other articles of food it has run over, cauſes a violent colic in thoſe who happen to eat them; it frequently ſtands in an erect poſture on its hind-feet; from the peculiar ſtructure of its feet the animal is enabled to attach itſelf to the ſmootheſt ſurfaces.

There is a variety of this ſpecies denominated *Tokai*, deſcribed by the Jeſuit miſſionaries ſent by Lewis XIV. to Siam; of which the body is covered above by a granulated ſkin, varied with red and blue undulations; the belly is of an aſh colour, and interſperſed with red ſpots; the head is large and triangular. It is a native of Siam, and is regarded as a poiſonous animal. Bontius, in his Hiſtory of Java, appears to deſcribe one of a ſimilar kind, under the name of the Indian ſalamander. It is called Gecko, on account of its ſhrill cry. It is about a foot long, and its colour is ſea-green, ſpotted with red, the head is large and toad-like; the eyes are large and extremely protuberant. It is ſaid that the Javaneſe hold up the animal by the tail to make it diſcharge ſaliva from the mouth, which they collect and preſerve for the purpoſe of poiſoning their arrows.

Geitje. Tail lanceolate, middle-ſized; fore-feet with four toes; this ſpecies is found at the Cape of Good Hope. It is called by ſome naturaliſts *Sparmanniana*, on account of its having been firſt deſcribed by Sparmann. Its colour on the upper parts is a variegation of darker and lighter ſhades, and on the under parts it is whitiſh. It is looked on as a poiſonous animal, and is ſuppoſed to ſecrete from its pores a fluid which produces tumours and even gangrenes, that are ſometimes cured by the application of citron juice, but which, if long neglected, are very productive of dangerous ſymptoms.

Section G. The animals in this diviſion have feet with five toes; ſome of which are connected; the tail is round, ſhort, incurved.

Species.

Chamæleon. Three varieties are mentioned in the Syſtema Naturæ, of which the ſpecific character of the firſt is, body cinereous; head flat; of the ſecond the body is white; and of the third the head is very large.

The chamæleon inhabits India and New Spain; it lives chiefly in trees: from the anatomical deſcription, the lungs are large, and capable of being inflated to an enormous ſize by the animal; the eyes are ſo moveable that the creature can look in different directions at the ſame time; the pupil has a golden glare, and frequently changes its colour.

Few animals have been ſo much celebrated as the chamæleon, which, it was long believed, has the power of changing its colour at pleaſure, and of aſſimilating it to that of any particular object or ſituation. This, however, is not the real ſtate of the caſe; the change of colour which the animal exhibits varies in degree according to the circumſtances of health, temperature of the weather, and other cauſes, and conſiſts chiefly in an alteration of ſhades from the natural greeniſh or blueiſh-grey of the ſkin into pale yellowiſh, with irregular ſpots of dull red. Another erroneous aſſertion with regard to the chamæleon was, that it could ſubſiſt on air. This aroſe from the long abſtinence which it is known capable of enduring.

The length of the chamæleon is about ten inches, but including the tail, it is nearly double that length. The ſkin on every part of the animal is granulated. There are five toes on each foot, two and three of which are united by a common ſkin as far as the claws. The ſtructure of the tongue is peculiar; it is very long, and furniſhed with a dilated ſomewhat tubular tip, by which means it is enabled eaſily to ſeize inſects, by darting it out and ſecuring them on the tip. It is found in many parts of the world, and particularly in India and Africa; and has been ſeen in the warmer parts of Spain and Portugal. For a farther account of this animal, ſee Chamæleon.

Africana; or African lizard. Black; head carinate; it inhabits the northern parts of Africa and Spain; in its habits it reſembles the chamæleon; the protuberant parts are all white.

Pumilla; Dwarf lizard. Sides blueiſh, with two yellowiſh lines; it is found at the Cape of Good Hope. In this ſpecies the head is ſomewhat flatter than that of the Africana, but ſtill elevated in the middle, and edged on each ſide with a denticulated margin. The Africana and the Pumilla have been regarded, by ſome naturaliſts, as varieties of the ſame ſpecies.

Section H. The animals of this diviſion have their collar double; and ſquare abdominal ſcales.

Species.

AMEIVA; the blue lizard. Tail verticillate, long; abdominal ſcales thirty; collar beneath with a double wrinkle. It inhabits America, but occurs in Africa and Aſia. The abdominal ſcales are in eight rows.

TILIGUERTA. Tail verticillate; twice as long as the body, abdominal ſcales eighty. It is about ſeven or eight inches long, and is found during the whole year in the fields and meadows of Sardinia.

AGILIS; Scaly or green lizard. Tail long, verticillate, with ſharp ſcales; collar is ſcaly beneath. This elegant ſpecies, which is found in all the warmer parts of Europe, varies in length from fifteen inches to two feet. It is the moſt beautiful of all the European lacertæ, exhibiting a rich and varied mixture of darker and lighter green, interſperſed with ſpecks and marks of yellow, brown, blackiſh, and even ſometimes red. The head is commonly of a more uniform green than the reſt of the body; the under part of the animal, both on the body and limbs, is of a pale blue-green caſt; the head is covered with large angular ſcales; the reſt of the upper parts with very ſmall ovate ones; the tail, which is commonly longer than the body, is marked with numerous rings of oblong-ſquare ſcales, ſlightly bifid at their extremities; beneath the throat is a kind of collar, formed by a row of ſcales of much larger ſize than the reſt: the abdomen is covered, down its whole length, with ſix rows of broad tranſverſe plates, and the under ſurface of the limbs is alſo covered with ſimilar ſcales; along the inſide of the thighs runs a row of papillæ or tubercles, about thirteen in number, which, in this and other ſpecies, probably aſſiſt the animal in climbing or clinging to the ſtems and branches of vegetables; the tongue is moderately long, and formed to enable the animal to retain and ſwallow its prey, which conſiſts chiefly of inſects, ſmall worms, &c.

This ſpecies is a native of all the warmer parts of Europe. It is found in gardens, about and in crevices of warm walls, buildings, &c. It is, as its name imports, a very active animal, and purſues its prey, which conſiſts of inſects, with great celerity. When it is caught it may be tamed, and it ſoon becomes familiar.

It appears to run into numerous varieties both as to ſize and colour; but in them all the particular characteriſtics of the ſpecies are eaſily aſcertained. Beſides the one already deſcribed, we have in the Syſt. Nat. the following varieties: 1. One in which the loweſt ſcales of the collar are looſe. 2. That in which the ſkin is very thin and of a brown colour. 3. Body with eye-like ſpots. 4. Brown; on each ſide a ſeries of indiſtinct ſpots. 5. Sides brown; back tawny. 6. Blueiſh; each ſide a triple row of ocellate ſpots. 7. Green ſpeckled with brown; collar tawny. 8. Blue; head white; back longitudinally ſtriate; hind-legs ſpotted. 9. Blue; the ſides ſpeckled with white.

The 8th, found in America, is deſcribed as innocent, active, elegant, living in dry meadows, walls, and rocks. Some of the animals of this ſpecies have been uſed as a medicine, and have been ſuppoſed to poſſeſs peculiar virtues in leprous and other ſimilar caſes.

SEPS; the eft. Tail verticillate, long; lateral ſuture reflected, ſcales ſquare.

This is a ſmall ſpecies, and is eaſily known from the thin lengthened form of the body, and its long ſlender tail. There are three varieties, the firſt anſwers to the ſpecific character given; the ſecond is variegated with cheſnut; head varied with black and white; the third is black-blue, marbled with confluent white bands mixed with round ſpots. It inhabits ſouthern countries. The body is covered above and beneath with truncate ſcales in eight rows, forming lateral and longitudinal ſtreaks, belly flat; tail with about 50 whorls, half as long again as the body; legs ſhort, diſtant, but well formed for running. See EFT.

VELOX; Swift lizard. Tail verticillate, longiſh; collar beneath ſcaly, body above cinereous, varied with five longitudinal paler ſtreaks and brown dots; ſides ſpotted with black, dotted with blueiſh.

This ſpecies is found in Siberia, particularly in the ſultry deſert places about the lake of Inderſkien; it wanders among the rocks, and is exceedingly ſwift; it reſembles the ſcaly or green lizard, but is much ſlenderer and leſs; hind-legs marked with round patches.

CRUENTA; Red-tailed lizard. Tail verticillate, above cinereous, beneath ſcarlet with a whitiſh tip; fold of the neck beneath tranſverſe. This ſpecies is found about the ſalt lakes in ſouthern Siberia; reſembles the velox in ſhape, but is three times as ſmall, and has a ſharper head. The body is brown, with ſeven white ſtreaks on the neck, of which four reach the tail, beneath is white; limbs varied with round milky ſpots; thighs without the line of callous dots.

ARGUTA; the argute lizard. The ſpecific character is this; tail ſhort, verticillated; thick at the baſe and filiform at the tip; collar marked with obſcure ſcales. There is a remarkable double plate under the neck.

The ſpecies is ſimilar in ſome reſpects to the green lizard, but is ſhorter and more ventricoſe, and has a ſharper ſnout. It is a native of the ſouth of Siberia, and is found in the dry ſunny places of Irtiſh, and on the ſandy plains beyond.

ALGIRA. Tail long and verticillated, and two yellow lines on each ſide the body; it is a ſmall ſpecies, of about a finger's length; it is brown above, and beneath yellowiſh; back covered with carinated ſcales, and bounded on each ſide by a yellow line, ſeparating the abdomen from the upper parts. It is a native of Algiers.

TILIGUGU; Sardinian lizard. Tail round, conic, middle-ſized; toes five marginate claws.

It inhabits Sardinia, and is eight inches long. The body is thick, brown above, variegated with numerous black dots, beneath whitiſh; legs very ſhort, the hinder ones longer; tail three inches and a half long.

URALENSIS; Ural lizard. Tail round, longiſh; neck beneath folding; feet all-toed; back livid-aſh, wrinkled, and ſubwarted.

It inhabits the country about Ural, is four inches long; very ſwift. The head is roundiſh; body whitiſh beneath.

BULLARIS; Bladder lizard. Tail round, long; chin pouched.

This ſpecies is about ſix inches long, of a ſhining graſs-green colour. When it is approached, the throat ſwells into a globular form, and the protruded ſkin becomes of a bright colour. This has been thought to be a threatening aſpect, but probably without any foundation. It is a native of Jamaica, where it is common about hedges and trees. The green Carolina lizard is ſuppoſed to be a variety of this ſpecies, as it is an exact reſemblance in every reſpect, except in the appearance of the pouch. In dry hot weather it appears of a bright green colour; but in cold weather it changes to a brown. It is very common in and about the houſes of Carolina.

AURITA; Eared lizard. Tail round, middle-ſized, with callous dots on each ſide; the throat fold tranſverſe, almoſt double; angles of the mouth each ſide dilated into a ſemiorbicular, ſoft, rough, dentate creſt. This ſpecies is found among the ſandy hillocks of ſouthern Siberia, and gravel-pits in the deſert of Comani, it is ſomething larger than the gecko; the upper part waved with cinereous and yellowiſh, and thickly ſpeckled with brown; underneath it is whitiſh; tip of the tail and blotch on the cheſt black.

TEGUIXIN. Tail round, long; lateral ſuture folded; neck beneath wich a triple fold. Inhabits India and South America. Back and tail verticillate with crowded ſtreaks.

HELIOSCOPA; Star-gazing lizard. Tail imbricate, tapering; neck with a tranſverſe fold beneath; head covered with calloſities. This ſpecies inhabits in vaſt numbers the burning ſand-hillocks of ſouthern Siberia; moves very quick, but in a leſs ſerpentine direction than the ſcaly lizard; holds its head very erect with its eyes turned upwards, and is about two inches long. The colour of the upper parts of the body is grey, with brown and blueiſh ſpots, and linear ſtreaks. The neck is often marked above with a red ſpot. The tip of the tail is red beneath.

PLICA; Plica lizard. The hinder part of the head is callous; eye-brows excoriated above; neck plaited beneath, and warted at the ſides; tail long and round. This is a ſmall ſpecies, about two or three inches in length. It is entirely covered with conical ſcales; there is a double plate beneath the throat. It is a native of South America and India.

Section I. Body lineate or banded, ſcaly; tongue bifid.

Species.

SEXLINEATA; Six-lined lizard. Tail verticillate, long; back with ſix white lines. It inhabits Carolina. The back is hoary, with three narrow white lines and three black; under the neck are two wrinkles; thighs with a row of callous dots behind.

QUINQUELINEATA; Five-lined lizard. This alſo is an inhabitant of Carolina. The head is marked with ſix yellow lines, and two between the eyes; back is blackiſh, with lines reaching to the middle of the tail; the tail half as long again as the body; the belly is ſtreaked imbricately.

NILOTICA; or the lizard of the Nile. Tail long, the outer ſide triangular; body ſmooth; back with four lines of ſcales. It is found in Egypt.

INTERPUNCTATA; Aſiatic lizard. Tail round, long; back with yellow lines, interſperſed with black dots. Inhabits different parts of Aſia. Body included between two lines and diſtinct from the ſides. In the area are ſix longitudinal rows of brown dots, and as many on each ſide; legs and tail dotted in the ſame manner.

LEMNISCATA; Eight-lined lizard. Tail round, long; back with eight whitiſh lines. It inhabits Guinea. The thighs are dotted with white.

FASCIATA; Blue-tailed lizard. Tail round, long, blue; back with five yellowiſh lines. Inhabits Carolina.

VULGARIS; Brown lizard, or common Newt. Tail round, middle-ſized; feet clawed; fore-feet four-toed; back with a double brown line.

It inhabits Europe, and is about three inches long. It is found in gardens, in the neighbourhood of dunghills, &c. Like the ſlug and toad it makes its way into cellars. It is altogether a land ſpecies, and it ſeems to be viviparous.

JAPONICA; Japoneſe lizard. Tail round, long; feet clawed; fore-feet four-toed; back banded. Body beneath yellow; the upper part is livid, with a dentate broad yellow band from the hind-head to the tip of the tail; eyes ſmall; eye-brows large, rough; claws black; tail a little compreſſed at the tip. It is found in the Japan iſlands.

DESERTI; Ural lizard. Tail round, longiſh; feet five-toed; body above black, with ſix white longitudinal lines. It is found in the deſert of Ural, and is ſomewhat more than two inches long. The body beneath is white; lines of the back conſiſting of oblong ſpots, and between each outer line, and the next, are five white dots.

QUADRILINEATA; Four-lined lizard. Tail round, long; feet ſomewhat clawed; hind-feet four-toed; body with four yellow lines. It inhabits North America.

PUNCTATA; Dotted lizard. Tail round, middle-ſized; feet unarmed; fore-feet four-toed; back longitudinally dotted with white. It is found in Carolina. The body is brown, with a double row of white ſpots on the back, and a ſingle one on the tail.

SPUTATOR; Spitting lizard. Tail round, middle-ſized, with a longitudinal row of ſcales beneath; feet unarmed, five-toed; body cinereous, with white bands above, before and behind it is edged with liver colour. It is found in South America, in houſes and among old buildings; when irritated, it diſcharges a black acrid matter, the effects of which on the human body may be cured by camphor or ſpirits of wine. The whole animal, except the very tips of the jaws, and the lower ſurface of the tail, is covered with minute truncate ſcales; the tongue is round, a little notched at the tip; tail near the end, and legs ſpotted with brown.

Section K. The belly of the animals of this diviſion is covered with imbricate ſcales; the tongue is entire.

Species.

SEPIFORMIS. Tail ſhort; body greeniſh-black; head armed; back flat; hind-thighs on the hinder part covered with callous dots.

SCINCUS; Scink. Tail round, middle-ſized, compreſſed at the tip; toes unarmed, marginate. This ſpecies is thus characterized by Dr. Shaw. "Yellowiſh-brown lizard, with tranſverſe brown bands on the upper part, ſhort tail with compreſſed tip, and upper jaw longer than the lower."

"The ſcink," ſays the writer juſt quoted, "is one of the middle-ſized or ſmaller lizards, and is a native of many of the eaſtern parts of the world. It abounds in Lybia, Syria, Egypt, and Arabia, frequenting moderately dry and ſandy ſoils, and growing to the length of ſix or ſeven inches, or even ſometimes more. The head of the ſcink is large, the body thick and round, and the tail conſiderably ſhorter than the body."

It is of a pale yellowiſh-brown colour, with a few broad, duſky, tranſverſe undulations or zones, and is uniformly covered with moderately large or fiſh-like ſcales, lying extremely cloſe and ſmooth, ſo that the ſurface has a gloſſy or oily appearance. It is an animal of harmleſs manners, and like moſt lizards derives its ſubſiſtence from various inſects, which wander about the regions that it inhabits. It was once in high eſtimation as an article in the Materia Medica.

Mr. Bruce, in his Travels, has deſcribed the ſcink under the name of El Adda, which, he ſays, is very common in the province of Atbara in Abyſſinia. (See *El* ADDA.) It burrows in the ſand ſo quickly, that it is out of ſight inſtantly, and appears rather to have found a hole than made one, yet it comes out in the heat of the day to baſk in the ſun; and if not very much frightened, will take refuge behind ſtones, or in the withered, ragged roots of the abſinthium, dried in the ſun to nearly its own colour. It has long legs, but makes no uſe of them to ſtand upright; it creeps with its belly almoſt cloſe to the ground; its motions are, however, very rapid. Mr. Bruce informs us, that lizards in general are peculiarly numerous in the eaſtern regions. The deſert parts of Syria bordering on Arabia Deſerta abound with them to ſuch a degree, as to render it impoſſible to count them. "I am poſitive," ſays the traveller, "that I can ſay, without exaggeration, that the number I ſaw one day in the great court of the temple of the ſun at Balbec, amounted to many thouſands; the ground, the walls, and ſtones of the ruined buildings were covered with them, and the various colours of which they conſiſted made a very extraordinary appearance, glittering under the ſun, in which they lay ſleeping and baſking.

Scincoides; Scincoid lizard. Tail round, middle-ſized; legs ſhort; toes very ſhort.

This ſpecies is a variety of the *occidua* of Dr. Shaw, to which he gives the name of the galliwaſp. It is nearly two feet long, according to him; but Gmelin makes it about eighteen inches only. It is a native of New Holland. The body is a pale yellowiſh-brown, with a long patch of deep brown or blackiſh each ſide the neck; ſides tinged with the ſame colour; tail deeper than the ſides; teeth ſomewhat obtuſe, ſhort. The tongue in this, as in other ſcinks, is ſhort, flat, rounded and entire; not forked, as in moſt lizards.

The occidua or galliwaſp itſelf is a native of the American iſlands, and is particularly common in Jamaica, where it frequents woody and marſhy diſtricts. Its colour is uſually a paliſh brown, clouded with ſomewhat irregular bands of a deeper caſt; but it is ſaid occaſionally to change its colour into a lively golden yellow. It was formerly thought to be the moſt venomous reptile in the iſland of Jamaica, and it was ſaid that no creature could recover from its bite; but this is now regarded as a popular error.

Ocellata; Ocellate lizard. Tail roundiſh, ſhort; body beneath white, above greeniſh-grey, with roundiſh ocellate ſpots, brown on the margin, rectangular and white on the diſk. It is found in Egypt, is very beautiful, and about a ſpan long.

Guttata; Spotted ſcink. Tail round, long, the tip and four tranſverſe ſpots black; body above hoary, dotted with white, beneath whitiſh.

It is a very ſmall ſpecies, not much exceeding three inches in length. It inhabits the deſerts of Ural. The body is ſmooth above; the feet are five-toed, with claws.

Section L. The animals of this diviſion crawl on the belly; reſembling both the lizard and ſerpent.

Species.

Chalcides. Tail round, long; feet five-toed; legs very ſhort. Inhabits ſouthern Europe and Africa. It is found of different ſizes, from the length of a few inches to that of a foot, or even more. The head is covered in front with large ſcales, and is terminated by a ſlightly tapering, but not pointed, ſnout; the eyes are ſmall, and the openings of the ears very diſtinct. There is no neck, the diameter continuing nearly equal from the head to the beginning of the tail, which is often longer than the body, and gradually tapers to a ſmall point. The colour of this animal is pale ferruginous, or cheſnut brown; hence its name, with ſome naturaliſts, is the "Ferruginous lizard."

In the living animal, the colour is generally ſaid to have a kind of metallic or braſſy caſt, which probably gave riſe to the ſpecific appellation "Chalcides," and "Chalcidica."

"This ſingular lizard," ſays Dr. Shaw, "is deſcribed by Linnæus as having feet furniſhed with five toes; but whatever may have been the caſe with the individual ſpecimen which he examined, it ſeems pretty certain that the general number is three. In the Britiſh Muſæum is an elegant ſpecimen. The chalcides is an animal of a very harmleſs nature, frequenting moiſt ſhady places, moving rather ſlowly, and feeding on inſects, ſmall worms, &c. It is a viviparous ſpecies, and is ſaid to produce a great many young. The ſerpents to which it bears the neareſt alliance, in point of form, are thoſe of the genus anguis, and particularly the A. fragilis, or common ſlow-worm."

The "Chalcide," deſcribed by the count de Cepede, appears to be extremely allied to the one juſt mentioned; but, inſtead of having imbricated ſcales, it is marked into a continual ſeries of annuli throughout its whole length.

Serpens; Serpent lizard. Head, body, and tail, a continued cylinder; legs very minute, remote, five-toed, and clawed. It inhabits Java; is about four or five inches long. Its ſhape is very much like that of a ſerpent, but more conical; the upper part of the body is decorated with from fourteen to twenty brown, longitudinal ſtripes; beneath it is ſilvery. It has an auditory canal.

Anguina; Snake lizard. Tail verticillate, ſtiffiſh at the extremity; body ſtriate; feet without toes, ſubulate. The animals of this ſpecies are about fourteen inches long, of which the body itſelf is only four. The head is rather ſmall; the noſe taper; the legs very ſhort, placed near the head and vent, and apparently terminating in one undivided toe or proceſs; the whole animal appears covered with ovate ſcales, and is brown above, aſh-coloured on the ſides, and yellowiſh beneath; the upper ſurface is marked throughout its whole length by ſeveral dark lines or ſtripes. It is a native of the Cape of Good Hope, where it is found in great plenty in the water, and about the rocks in the Table bay.

Lumbricoides; Lumbriciform lizard. Body ſubequal, round, ferruginous, teſſellate with ſquare ſtreaks; beneath paler; there are no hind-feet, but the others are ſhort and four-toed. This is the la cannellè of the count de Cepede, who firſt deſcribed it in his Hiſtory of Oviparous Quadrupeds. Its length is about eight inches, of which the tail is only one inch. Along the whole body, from head to tail on each ſide, runs a continued ſulcus or channel, ſeparating the upper and lower ſurfaces; legs only two, extremely ſhort, placed near the head, and divided into five minute toes with claws. Colour of the living animal ſuſpected to be green; paler beneath. It inhabits Mexico.

Bipes; Biped lizard. Body ſubequal, round, pale, imbricate; each ſcale with a brown dot. There are no fore-feet; hind-feet with two toes. This is a very ſmall ſpecies, ſaid to be found in South America and in India. Its length is ſix inches; the diameter no larger than that of a good-ſized gooſe-quill. This lizard was deſcribed by Linnæus in the Muſæum Adolphi Frederici, as a ſpecies of ſnake, under the title of "Anguis bipes."

Apus; Cylindrical lizard. Head, body, and tail, a continued imbricate cylinder; it has no fore-feet, and ſcarcely any that can be ſo called behind. This ſpecies is a ſtill nearer approach to the ſnake tribe than even the chalcides. It is a native of Greece, the ſouthern parts of Siberia, and probably of many other parts of Europe and Aſia. It is ſometimes full three feet long, and ſo perfectly reſembles the general form of a large ſnake, that it requires very cloſe inſpection to find that it belongs to the race of lizards. It inhabits the graſſy meadows of the deſerts of ſouthern Siberia, and near the rivers Sarpa, Cuma, and Terek. Though in general appearance it reſembles a ſnake, in its internal ſtructure it is formed like a lizard.

Two ſpecimens of this lizard were brought from Greece by Dr. John Sibthorp, profeſſor of botany in the univerſity of Oxford.

Having, in the foregoing account, followed the Linnæan ſyſtem, with ſuch occaſional additions and illuſtrations as occurred from other writers of diſtinguiſhed reputation; we ſhall conclude with noticing ſome ſpecies which later naturaliſts have added to this genus, and which have been deſcribed, and moſt of them figured, in the intereſting works of Dr. Shaw. Of theſe the firſt is the

Acanthura. The ſpecific character of this is as follows: Throat plaited beneath; the body covered with minute ſcales; the tail long, and verticillated with carinated triple-ſpined ſcales. A ſpecimen of this animal is preſerved in the Britiſh Muſæum. Its length is a foot and a half; the head reſembles that of the ameiva and teguixin, is covered with rather ſmall ſubhexagonal ſcales, and is very diſtinctly marked off, as it were, from the body; beneath the throat is a conſpicuous tranſverſe plait; the whole ſkin about the neck, throat, and beginning of the ſides, is very lax, ſo that it is thought in the living animal the ſkin beneath the throat may have a kind of pouch appearance, though entirely without any middle carina on that part; the feet are all pentadactylous, and the toes rather long. The colour of this ſpecies on the upper part is glaucous, variegated with a few ſmall and ſomewhat indiſtinct clouds and marblings of a whitiſh caſt; the tail and under parts are of a pale or yellowiſh-white colour. Dr. Shaw ſays, this ſpecies is much allied to the quetzpaleo of Seba, which is generally ſuppoſed to repreſent the azurea of Linnæus.

Lophura. Body covered by diſſimilar ſcales; the back ſerrated; the tail is long and carinated. This is a very large ſpecies, reſembling the teguixin in ſize, colour, and ſome other reſpects, but is coated with ſcales of diſſimilar ſize on different parts. Specimens are found in the Britiſh Muſæum, and in that of Dr. William Hunter.

Erythrocephala. Blackiſh-green, with tranſverſe black undulations; abdomen longitudinally banded with black, white, and blue; the breaſt black, and the top of the head red. This, which is reckoned a middle-ſized ſpecies, is a native of the iſland of St. Chriſtopher, and is deſcribed by the count de Cepede. Colour deep or dark green above, mixed with brown; back marked by ſeveral tranſverſe black undulations; top of the head and part of the ſides of the neck red; throat white; breaſt black; belly variegated with longitudinal black, blue, and whitiſh bands, and covered with ſcales or plates. The head is covered with larger ſcales than the other parts; beneath the thighs is a row of tubercles.

Teniolata. Lizard with long round tail, and body marked above with black and white ſtripes; beneath it is white. This ſpecies, allied to the faſciata, is covered entirely with ſcales; colour cheſnut brown above; pale or whitiſh beneath; on the back ſix narrow white linear ſtripes, the intermediate ſpaces of the central and lowermoſt ſtripes being black; the tail is long and narrow; limbs ſtriped longitudinally with black. It is ſlender, five-toed, and a native of New Holland.

Sinensis. Tail flat, all the toes unguiculated, and the face perforated by ſeveral pores. This ſpecies, which is omitted in the Syſt. Nat., was firſt deſcribed by Oſbeck, who obſerved it in China, where it is frequently ſeen in houſes, running about the walls, and climbing with extreme readineſs on the ſmootheſt ſurfaces, preying chiefly on the ſmaller kind of blattæ.

Fimbriata. Body with a membranaceous fimbriated border on each ſide of the body, tail flat, and lamellæ of the feet divided by a furrow. This ſpecies was firſt deſcribed by the count de Cepede, who informs us that it appears in ſome degree to connect the chamæleon, the gecko, and the water-newts: the head, ſkin, and general form of the body, reſembling thoſe of the chamæleon; the tail, that of the water newts; while the feet reſemble thoſe of the gecko.

The colour of this animal is not conſtant or permanent, as in moſt of the lizard tribe; but variable, as in the chamæleon, preſenting ſucceſſively ſhades of red, yellow, green, and blue. This variation of colour is confined to the upper ſurface of the animal; the lower always continuing of a bright yellow. Theſe ſeveral changes have been obſerved in the living animal in its native country, Madagaſcar, where it is rather common, and where, though harmleſs, it is held in great abhorrence by the natives, who believe that it darts on their breaſt, and adheres with ſuch force by its fringed membrane, that it cannot be ſeparated from the ſkin without being cut off. Its reſidence is on the branches of trees, where it lives on inſects, holding itſelf ſecure by coiling its tail half round the twig on which it ſits. It chiefly appears in rainy weather, when it moves with great agility, often ſpringing from bough to bough.

Lizard, *Devil.* See Maboujas.

Lizard, *Fly-catching.* See Gobemouch.

Lizard *Iſland*, in *Geography*, one of the iſlands called "Direction iſlands," in the South Pacific ocean, about 240 miles in circumference, and in general rocky and barren. Captain Cook gave it the name on account of the number of lizards, ſome of which were very large, which he found upon it; 20 miles N.E. of Cape Flattery.—Alſo, one of the ſmaller Bahama iſlands.

Lizard *Point*, or *The Lizard*, a promontory on the ſouth coaſt of Cornwall, and the moſt ſouthern point of land in England, at the north entrance of the Engliſh channel. N lat. 49° 59′. W. long. 5° 12′.

Lizard, in *Naval Rigging*, an iron thimble ſpliced into the main bow-lines, and pointed over to hook a tackle to.

Lizard's *Tail*, in *Botany*. See Saururus.

LIZENED Corn, in *Agriculture*, a term provincially uſed for ſhrunk or lank corn.

LIZIERE, the ſame with *berme*, *foreland*, or *relais*.

When this ſpace is covered with a parapet, it is called a fauſſe-braye, or low wall.

LIZOU-TCHEOU, in *Geography*, a city of China, of the firſt claſs, in the province of Quang-ſi, on the river Long. N. lat. 24° 12′. E. long. 108° 47′.

LIZY-sur-Ourcq, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the diſtrict of Meaux. The place contains 1200, and the canton 11,885 inhabitants, on a territory of 245 kiliometres, in 28 communes.

LLALA, a town of Peru, in the audience of Lima; 100 miles N. of Lima.

LLAMA, or Glama, in *Zoology*. See Camelus.

LLANBADARN-Vawr, in *Geography*, a market town and pariſh in the hundred of Genecin Glyn, Cardiganſhire, Wales. This place is ſuppoſed to have been anciently called *Mauritania*, and to have changed its name in the ſixth century, in memory of St. Paternus, who built a monaſtery here, which was afterwards conſtituted an epiſcopal ſee. This dignity it retained till the inhabitants, quarrelling with the biſhop, murdered him, when it was united to the ſee of St. David's. The government of the town is veſted in a portreve. It has a ſmall harbour; but the little trade it formerly poſſeſſed has of late years been transferred to Aberyſtwith. The market for meat is now likewiſe held at the ſame place, ſo that this town is much declined. The ancient church, built in the form of a croſs, and ſurmounted by a maſſive ſquare tower, is a large edifice, in an early ſtyle of architecture. It is remarkable as the ſeat of one of the oldeſt biſhoprics in Wales. The interior contains a few modern monuments, one of which was raiſed to the memory of Lewis Morris, the celebrated author of the "Celtic Remains." In the church-yard is an ancient croſs, finely decorated with fret-work. The pariſh is very extenſive, and contains a number of hamlets, of which Aberyſtwith is the largeſt and moſt populous. The waſte lands, or commons, may be about 8000 acres. Several old Britiſh forts and tumuli can eaſily be traced in different parts of it. In a vale, called Dyfryn caſtell, is a circle of ſtones, which tradition informs us was a Druidical temple and court of judicature. This town and pariſh were entirely laid waſte by the Danes in the year 988. The town was ſoon rebuilt; but in little more than thirty years after again ſuffered a ſimilar fate, being burnt to the ground by Gruffydd al Llywellin, during his conteſt for the ſovereignty of this diſtrict with Howel ap Edwin. The houſes in this pariſh, according to the parliamentary returns of 1800, amounted to 249 in number, and the inhabitants to 1228. For an ample and intereſting account of this pariſh and the county, the reader is referred to a volume recently publiſhed by S. R. Meyrick, entitled "The Hiſtory and Antiquities of the County of Cardigan," 4to. 1808.

LLANBEDER, Llampeter, or *Llanbedrpont-Stephen*, a market-town and pariſh in the hundred of Modwin, and county of Cardigan, South Wales. It is a corporation, governed by a portreve, bailiff, and town-clerk, and joins with Cardigan, Aberyſtwith, and Aſpar, in returning one member to parliament. The addition of Pont-Stephen to the name of this place is ſuppoſed to have ariſen from the circumſtance of king Stephen having thrown a bridge over one of the principal trenches of a camp in this vicinity. The market is held here on Tueſday. The principal traffic conſiſts in horſes, cattle, and hogs, vaſt numbers being bought for the Engliſh markets. The foundations of a noble caſtle, which anciently ſtood in this neighbourhood, can ſtill be diſcovered at a very ſhort diſtance from the town. The old family manſion of the Lloyds forms a very curious and pictureſque object. It is ſurmounted by four lofty turrets, which, peeping through a thick planted incloſure, have a ſtriking appearance. The pariſh is ſmall, and the ſoil remarkably unproductive, though much improved of late years, by the free uſe of lime. The houſes, according to the parliamentary returns of 1800, amount to 161 in number. The inhabitants were eſtimated at 669. Meyrick's Hiſtory, &c. of Cardiganſhire, 4to. 1808.

LLANDAFF, *i. e.* the church upon the Taff, a city in the hundred of Kibbor, and county of Glamorgan, South Wales. It is watered by the river Taff, which falls into the Severn, about four miles below the town. The name of this place is ſuppoſed to be a corruption of the word Llanar-daff, ſignifying the church on the Taff, the walls of the cathedral burying-ground being cloſe upon its banks. Llandaff, though a very ancient city in appearance, is only a ſtraggling village, placed on an eaſy eminence. The pariſh includes the hamlets of Canton, Elay, Fairwater, Gabalfa, and Llandaff. The pariſh comprehends 2399 acres of land. It has no market; but has the advantage of a tolerably good harbour, which opens into the Briſtol channel. This place is now chiefly ſupported by Cardiff, which is two miles W.N.W. It deſerves notice principally on account of its cathedral-church, which is ſaid to have been firſt founded here ſoon after the introduction of Chriſtianity into Britain, *i. e.* A. D. 186. It was not, however, till the beginning of the ſixth century, that Llandaff was raiſed to the dignity of a biſhop's ſee, by Myric, king of the Silures, who endowed it with all the lands between the rivers Taff and Elwy. The original church being deſtroyed at the time of the conqueſt, or at leaſt its oldeſt part, the preſent was erected in the year 1120, by biſhop Urban. Its ſituation is truly monaſtic, in a bottom ſurrounded by riſing ground. According to Groſe, it meaſures in length, from eaſt to weſt, 263½ feet. The breadth of the body is 65 feet, and the height from the floor to the centre of the roof 119 feet. The weſt front is a beautiful relic of the Norman and pointed ſtyles of architecture united. At the corners of this front formerly roſe two magnificent towers, one of which is now nearly deſtroyed. That on the north-weſt, ſtill remaining entire, is embelliſhed with a profuſion of ſculpture. The entrance on this ſide is under a ſemi-circular arch, over which are three windows, with lancet-ſhaped arches. The interior contains ſeveral monuments of the biſhops; alſo, one in honour of the lady Godiva, the celebrated patroneſs of the men of Coventry. A full deſcription of this church, with views and details, will be found in N° 1. of Cooper's Architectural Reliques. Nothing can exceed the abſurd and fantaſtical appearance of this edifice, when viewed as a whole. Beneath the towers has been ingrafted an Italian ſummer-houſe, with a Venetian window, alſo pilaſters and flower-pot jars upon the parapet. The eccleſiaſtical eſtabliſhment of this ſee conſiſts of a biſhop, as dean, an archdeacon, a ſub-dean, a chancellor, precentor, and nine prebendaries. The choral-ſervice has long been diſcontinued; and the cathedral uſed as the pariſh church. A chapter-houſe, in the kitchen, and an office for the proctor-general, have been erected in the church-yard, where the officers meet once a-year at Peter's-tide, for the auditing of accounts, &c. Two vicars are appointed by the chapter to ſerve Llandaff and Whitechurch alternately. The petty ſeſſions for the hundred of Kibbor are holden at Llandaff. The biſhop has no palace here, nor are there any eſtabliſhed houſes for other members of the church. The dioceſe contains about three-fourths of the county of Glamorgan, and all Monmouthſhire, but ſeven pariſhes. A gate-way and a ruined tower, which formerly contained the great bell called Peter, now at Exeter, are the only remains of the biſhop's palace. The names of the prelates of this ſee have been preſerved by hiſtorians from the period of its erection, though with much uncertainty as to the dates of their conſecrations and deaths, till the cloſe of the ninth century. Llandaff, according to the parliamentary returns of 1801, contains 191 houſes, and 860 inhabitants. Two fairs are held here annually, one on the 9th of February, and another on Whit-Sunday. Brown Willis has publiſhed an hiſtory and deſcription of Llandaff cathedral in 1 vol. 8vo. See Malkin's Account of South Wales, 2 vols. 8vo. and Donovan's Tour through South Wales, &c. 2 vols. 8vo. Hoare's Edition of Giraldus Cambrenſis, 2 vols. 4to. 1809.

LLANDEILO Vawr, a market-town and pariſh in the hundred of Penfedd, and county of Caermarthen, South Wales. The town is ſituated on the declivity of a hill, at the bottom of which flows the river Towy, or Tywi, giving name to one of the moſt delightful vales in the county. The town itſelf has very little to recommend it, the ſtreets being extremely narrow, ſteep, and irregular. The church is an ancient low building, and conſiſts of two aiſles. The pillars which ſupport the roof do not exceed five feet in height. A market, held here every Saturday, is well ſupplied with proviſions. Llandeilo is 15 miles E. by N. from Caermarthen, and 202 W. by N. from London. No leſs than eight fairs are held annually in this town, and another at Fair-Fach, about one mile diſtant. The pariſh comprehends an area of about 16 miles from north to ſouth, by eight miles from eaſt to weſt. About one-tenth part of this land is uncultivated. On an eminence about one mile diſtant from the town, to the S.W. ſtands the pictureſque ruins of Dinevor, or Dinas-fawr caſtle, which commands ſome of the fineſt and moſt romantic views of the ſcenery of Newton-park, and the extenſive vale of Tywi. This caſtle was built by Rhys ap Theodore, in the reign of William the Conqueror. It ſeems to have been originally of a circular form, and ſtrongly fortified by a double moat and rampart. This caſtle was for ſome time the royal reſidence of the princes of South Wales. South from it are the ruins of Cappel yr Ywn, ſtanding between two round towers. It was formerly a chapel of eaſe to the mother-church. At ſome diſtance to the weſtward is Grongar-hill, which has been immortalized by the muſe of Dyer. At a ſhort diſtance, on a rugged hill, ſtand the mouldering fragments of Druſlwyn-caſtle. About four miles S.E. of the town are the pictureſque ruins of Craig-Cenen-caſtell, *i. e.* the caſtle on the rock by the Cenen. The ſituation is ſingularly romantic, being ſeated on an inſulated rock, which was inacceſſible on all ſides but one. It is ſuppoſed to have been erected by Goronw, lord of Is-Cenen, who was one of the knights of king Arthur's round table. The well in this caſtle is conſidered a ſingular curioſity. The farm-houſe, called Cwrt Bryn y Beirdd, which lies about a mile to the ſouth of this caſtle, was formerly a celebrated bardiſh reſidence. Here the river Llychwr takes its riſe, iſſuing with a copious ſtream immediately from the ſolid rock. Cloſe to this ſpring is a cavern, in ſome places ſo narrow, as hardly to permit a perſon to paſs through, but in other parts extremely ſpacious, and exhibiting a variety of beautiful petrifactions. At Llan-de-Faen, which lies to the ſouth-weſt, at the diſtance of four miles, is a well formerly conſidered as very efficacious in paralytic and ſcorbutic affections. Beſides this, there are other chalybeate ſprings in different parts of the pariſh; but none poſſeſs any peculiar medicinal properties. Near Llandeilo-vawr are Talieris-park, the ſeat of lord Robert Seymour; and Edwinsford, the ſeat of J. H. Williams, eſq. The river Tywi, which, paſſing the town, meanders along the vale, abounds with excellent ſalmon-trout and eel. According to the hiſtory of Wales, by Carradoc of Llancarvan, the laſt deciſive battle between the forces of Edward I. and Llewellin, prince of Wales, was fought in this neighbourhood. The victory remained with the Engliſh, and put a final period to the independence of Wales. The inhabitants of Llandeilo, according to the parliamentary returns for 1801, are eſtimated at 647, and the houſes at 141. Wyndham, Skrine, Malkin, Barber, and ſir Richard Hoare, in Giraldus Cambrenſis, have given accounts of this town and its neighbourhood in their reſpective Tours.

LLANDOVERY, or LLAN YM DDYFRI, a market-town and pariſh of Llan-Dingad, and hundred of Penfedd, Caermarthenſhire, South Wales. The town is ſituated on the river Brane, near its junction with the Towey, and conſiſts of five ſtreets, containing, according to Mr. Carliſle, about 800 inhabitants. The buildings of this town have a low and mean appearance. On a mount near the centre of the town, and ſurrounded by a deep trench, are the ruins of a ſmall caſtle, built by Richard de Powers, and it is remarkable for the birth and reſidence of the celebrated Rees Pritchard, (Rhys Prytherch,) well known throughout Wales as author of the "Vicar's Book," a collection of very ſimple poetry. This caſtle was beſieged in 1116 by Gruffydd ap Rhys, who burnt the outer ward, and put a great part of the garriſon to the ſword: but his own troops, in effecting this object, ſuſtained ſo conſiderable a loſs, that he was compelled to raiſe the ſiege. The ſcite of this caſtle is very remarkable, being an inſulated rock of ſome elevation, totally unconnected with any adjacent riſing ground. A handſome ſtone bridge is here thrown acroſs the river Brane. The church ſtands on an eminence at one end of the town. It does not poſſeſs any thing worthy of being particularly noticed. The market is held on Friday every week, and, conſidering the extent of the place, is one of the largeſt and beſt ſupplied in Wales.

Llandovery is undoubtedly a town of conſiderable antiquity: it roſe upon the ruins of a Roman ſtation, which was at or near Llan-Fair-ar-y-Brynn, about half a mile diſtant. That theſe celebrated conquerors had a fixed reſidence there, is ſufficiently clear from the number of Roman bricks, earthen pots, coins, and other remains of antiquity, which have been diſcovered on that ſpot. This town was formerly a contributary borough to Caermarthen, but the privilege has been loſt for a conſiderable period. It ſtill, however, retains its charter, by virtue of which a bailiff is annually elected, as are likewiſe a recorder, a town-clerk, aldermen, and ſerjeants at mace; but their offices at preſent ſeem to be little more than nominal. The county magiſtrates hold here the petty ſeſſions for the upper diviſion of the hundred of Penfedd. It poſſeſſes no leſs than five benefit ſocieties, three for men and two for women, which are ſaid to be extremely advantageous to the ſubſcribers.

The neighbourhood of Llandovery is diſtinguiſhed by a moſt enchanting diſplay of the more placid deſcription of mountain ſcenery. The paſs of Cwm-Dwr, which winds round the Black mountain to the eaſt, is peculiarly fine. On a part of this mountain the decayed town of Trecaſtle is ſituated; but it contains nothing worthy of attention, except the remains of a caſtle erected by Bernard de Newmarch, in the reign of William Rufus. On the ſummit of the Gaer hill is a Roman encampment, part of the fortifications of which are ſtill tolerably entire; and on Pen y Craig an oval one, with three foſſes and two vallums, ſuppoſed to be of Britiſh conſtruction. A monumental ſtone, about ſix feet high, called Maen y Morynnion, is placed on an old Roman cauſeway which joins the road to Brecknock. It ſeems to have been richly ſculptured. The words "Conjux ejus" are the only ones of the inſcription that can now be diſtinguiſhed. Carliſle's Typographical Dictionary of Wales, 4to. 1811. Skrine, Malkin, and Evans's Tours in South Wales.

LLANDRINDOD, or TRINITY-CHURCH, a village of South Wales, in Radnorſhire, near which are medicinal ſprings, much frequented; 8 miles W. of New Radnor.

LLAN-ELLY, a market-town and pariſh in the hundred of Carnwyllion, in Caermarthenſhire, South Wales, contains, according to the parliamentary returns in 1801, 501 houſes, and 2972 inhabitants. The market-days are Thurſday and Saturday. The buildings of the town are irregularly ſituated upon a creek near the ſea-ſhore. At the mouth of this creek is a ſmall iſland, formed by the river Bury, where a monaſtery, founded by St. Piro, formerly ſtood. The church, dedicated to St. Elliw, is an old ſtructure, remarkable for its high, ſquare, embattled tower. The inhabitants of this place are chiefly miners and ſailors. The coal wrought in the vicinity is reckoned remarkably fine. The harbour is tolerably large, and is the controuling port both for Caernarvon and Kidwelly. Two fairs are held here annually; one on Aſcenſion day, and the other on the 30th of September. The pariſh contains about 15,000 acres of land, of which nearly 3000 lie uninclosed and without cultivation. The hamlets are Berwich, Glynn, Hên Coed, Weſtſtowe, and the Borough hamlet. At Berwich and at Ddewi the ruins of two chapels can ſtill be diſtinguiſhed. The chapel of St. John has been lately repaired by ſubſcription, and is at preſent uſed as a meeting-houſe by the Methodiſts. Pembree-hill, a few miles diſtant from the town, commands one of the fineſt and moſt extenſive marine views to be found in any part of Great Britain.

LLANES, a ſmall ſea-port town of Spain, in Aſturias, near the North coaſt; 54 miles N.E. of Oviedo.

LLAN-GADOG-VAWR, a market-town and pariſh in the hundred of Penfedd, and county of Caermarthen, South Wales. The town, which ſtands between the rivers Brane and Sawdde, is tolerably well built, but was formerly much more extenſive than at preſent. It lies about 6 miles S.S.W. of Llandovery, and 190 W. by N. from London. A ſmall manufacture of coarſe woollens and ſtockings is carried on here, principally to ſupply the conſumption of the town. The market-day is Thurſday; and the fairs are held on the 12th of March, the laſt Thurſday of May, 9th of July, the firſt Thurſday after the 11th of September, and the ſecond Thurſday after the 11th of December. The ancient caſtle, mentioned by many touriſts, has been for many years entirely demoliſhed. A collegiate church is ſaid to have been founded here, A.D. 1283, by Thomas Beck, biſhop of St. David's, in honour of St. Maurice and his companion, and St. Thomas the Martyr. This diſtinction ſeems to have been enjoyed but a very ſhort time, if it ever actually took place. The preſent church is dedicated to St. Cadog, and the living is a vicarage in the gift of the biſhop mentioned above. Bledri, the ſon of Cedifor, the great lord of Gwydigada and Elfed, who died in 1119, was buried here. The pariſh contains three hamlets; the hamlet of Dyffryn Caead Rhych, the hamlet of Gwynfe, and the hamlet above the Sawdde. The population, according to the parliamentary report of 1801, amounted to 1821 perſons.

LLANGOLLEN, a market-town and pariſh, ſituated in the hundred of Chirk, and county of Denbigh, North Wales. The houſes of the town have a mean appearance. According to the parliamentary returns for 1801 they amounted to 281, and the inhabitants to 1287. The church is nowiſe remarkable, excepting for the length of the name of its patron ſaint, *i. e.* St. Collen ap Gwynnawg ap Clydawg ap Cowdra ap Caradog Fruchfras ap Lleyn Merim ap Eynion Yrth ap Cunedda Wledig. The market is held here on Saturday every week, and there are four fairs annually. The ruins of Caſtell Dinas Brân nearly cover the ſummit of a vaſt conoid hill, which begins its aſcent near the foot of the bridge oppoſite to the town. This is one of the primitive Welſh caſtles, but the name of its founder is unknown. The form of it is oblong, extending about 300 yards in breadth, and 150 in length. On one ſide of the hill, which is leſs ſteep than the others, deep trenches are cut through the ſolid rock. The materials compoſing this building are the common coarſe ſtone of the country, interſperſed with a few free-ſtone mouldings. In the reign of Henry III. this caſtle ſerved as an aſylum to the traitor Gryffydd ap Madog, who, baſely taking part with the enemies of his country, was compelled to ſecure himſelf in this aerial faſtneſs. It afterwards became the reſidence of Muſamvay Vechan, the beautiful and accompliſhed miſtreſs of Hoel ap Eynion, one of the moſt illuſtrious of the Welſh bards. It is remarkable that this caſtle ſtands at leaſt 600 yards above the level of the ſea: the two ſprings within its walls are never deficient in water. On the north-ſide of the hill may be ſeen a vaſt rock, called Craig Eglwyſeg, or the Eagle's Rock; the ſtrata of which are ſo placed upon one another as to form a ſeries of ſteps parallel with the horizon, known to naturaliſts by the name of Saxa ſedilia. The bridge at the bottom of the hill is one of the moſt beautiful and romantic in Wales, and is generally reckoned among the wonders of the principality. The foundation is on the ledge of a rock. It conſiſts of four arches, the centre one of which is 30 feet in diameter. Tradition informs us it was the work of Trevin, biſhop of St. Aſaph, in the year 1400. About two miles from the bridge ſtands the abbey of de Valle Crucis, one of the fineſt ſpecimens of architectural antiquity in Wales. The weſtern window has been adorned with a variety of ſculptural ornaments, but moſt of them are entirely defaced. Concerning the etymology of the name of this abbey hiſtorians are not agreed; ſome deriving it from the buildings being in the form of a croſs, and others from the circumſtance of its monks having made a preſent of a part of the true croſs to Edward I. At the diſtance of a quarter of a mile hence, is the remainder of a round column, called the pillar of Eliſeg, which is perhaps one of the moſt ancient Britiſh pillars now exiſting. It was entire till the time of the great rebellion, when it was thrown down and broken by ſome ignorant fanatics, on account of its reſemblance, in figure, to a croſs. This pillar has, no doubt, been erected to perpetuate the memory of ſome celebrated chief. It ſtood on a great tumulus, and, when complete, meaſured 12 feet in height. The inſcription was copied by Mr. Edward Llwyd, but it is now entirely illegible. From the ſhape of the letters in the copy taken by that great antiquary, it is concluded to have been written ſome time in the ſixth century. The tumulus was opened ſome years back, when ſome bones were diſcovered placed between flat ſtones.

The beauties of the vale of Llangollen are celebrated both in proſe and verſe. It is watered by the river Deva, and has a canal from the Pont y Cryſylltau aqueduct running throughout its whole length to the Oernant ſlate-quarries. The low price of labour, and the great plenty of proviſions and fuel, have lately induced ſeveral adventurers in the cotton manufacture to eſtabliſh ſome extenſive works in this neighbourhood. The great mail-road from London to Holyhead paſſes through both the vale and town. The pariſh is very extenſive, and is divided into three portions, called Traian y Glynn, Traian Llangollen, and Traian Trevor; each of which contains ſeveral hamlets. We might have mentioned the romantic reſidence of two ladies, who have for many years lived together in the vicinity of this town. It is well known by all touriſts. Pennant, Skrine, Bingley, Wyndham, Evans, Warner, and Hutton have given accounts of Llangollen, and of the principal places in its vicinity, in their reſpective tours in Wales.

LLANNERCH Y MEDD, a market-town, ſituated chiefly in the pariſh of Amlwch, in the hundred of Twr Celyn, and county of Angleſea, North Wales. A market is held here on Wedneſdays, and the fairs on the 5th of February, 25th of April, 6th of May, and Thurſday after Trinity. This town owes its ſupport principally to the circumſtance of its being ſtationed in the neighbourhood of the Parys mountain. The petty ſeſſions are held here. Aikin's Tour in North Wales.

LLANOS, Los, a town of Mexico, in the province of Mechoacan; 100 miles N.N.E. of Mechoacan.

Llanos *De Almeria*, a town of Spain, in the province of Grenada, on the coaſt of the Mediterranean; 20 miles W.S.W. of Almeria.

LLAN RHAIADAR, in Mochnant, a pariſh conſiſting of 17 townſhips, ſituated partly in the hundred of Chirk, and county of Denbigh, and partly in the hundred of Llan-Fyllin, in Montgomeryſhire, North Wales. It lies in a deep hollow, ſurrounded by lofty mountains. The petty ſeſſions for the diviſion of Cynllaeth and Mochnant are held in the village which gives name to the pariſh. William Morgan, D. D. an eminent divine, and the perſon who firſt tranſlated the bible into Welſh, was vicar here, till tranſlated to the ſee of Llandaff, by queen Elizabeth in the year 1595. The buildings of the village are ancient and irregular. The rectory is a ſinecure in the patronage of the biſhop of St. Aſaph. According to the parliamentary returns for 1801, the whole pariſh contained a population of 1869 perſons.

LLANRWST, a market-town and pariſh, ſituated in the weſtern extremity of the hundred of Uwch Dulas, and county of Denbigh, North Wales. The town is watered by the river Conwy, over which, at this place, is a noble bridge of three arches, built by the celebrated Inigo Jones in the year 1636. The market is on Tueſdays, and there are four fairs during the year. Here are held the petty ſeſſions for the hundred. Mr. Burke calls this "the moſt charming ſpot in Wales." In the town is a good market-hall, and a richly endowed free-ſchool. A ſmall trade is carried on in harp-making, and it is the centre of all the buſineſs of the populous vale in which it ſtands. The church is ſuppoſed to have been built in 570, and is dedicated to St. Grwſt, who was a biſhop of London about the year 360. In this church is ſome curious carved work, ſaid to have been brought from the neighbouring abbey of Maenan. Adjoining to it ſtands a chapel, erected by ſir Richard Wynne, after a deſign by the architect already mentioned. Here are a few monuments in honour of the Wynne family, which deſerve the attention of the curious. They are braſſes, each containing, beſides the inſcription, a portraiture of the perſon to whoſe memory they were engraved. An ancient monument of Howel Coytmor has been lately removed from the church to this place. Near it is a large ſtone coffin, ſuppoſed to be that of prince Llewelyn ap Jerwerth, who was denominated Llewelyn the Great. The high road from Shropſhire to Holyhead paſſes through the town. In the neighbourhood ſtands Gwydwhouſe, an ancient manſion, conſiſting of an extenſive pile of buildings, of irregular appearance, but ſufficient to denote the great opulence and ſplendour of its former poſſeſſors. Immediately behind the houſe the ground riſes rapidly to the foot of the perpendicular cliffs which form the weſtern boundary of the valley. All this ſpace is now covered with fine plantations of different kinds of trees. Half way up the rock, on an irregular plain of nearly five acres in extent, are the remains of a terrace, and a handſome domeſtic chapel, in the pointed ſtyle of architecture. About a mile from the town, at the hamlet of Mayne, is a ſpring in high repute for its medicinal virtues. Five miles to the ſouth-eaſt lies the ancient nunnery of Gwythwin, where St. Winefrid is ſaid to have been buried. The box which contained the relics of this ſaint is ſtill pointed out to ſtrangers, but her chapel on the ſouth-ſide is totally demoliſhed. The church-yard contains four upright ſtones, one of which is in the ſhape of a priſm, and bears an inſcription now illegible. North of Llanrwſt, at the diſtance of three miles, the abbey of Maenan formerly ſtood. Its ſcite is now occupied by a large old houſe, built out of the ruins. The reſident population of this pariſh, according to the parliamentary returns of 1801, amounted to 2549 perſons. See the Tours of Pennant, Wyndham, Aikin, Bingley, Skrine, Warner, Evans, and Hutton: all of whom viſited this part of Wales.

LLANSTEPHAN, a village in the hundred of Derllys, and county of Caermarthen, South Wales, is ſeated beneath a hill, in a woody vale; whence the ſituation is peculiarly pictureſque and intereſting. Here is a well, called St. Anthony's, which formerly was in high eſtimation for its medicinal virtues; but it has not been much reſorted to of late years. Here was formerly a caſtle, which is now in ruins. It is ſituated on an eminence, on the weſtern ſide of the entrance of the navigable river Tywi, or Towey. Its broken walls encloſe a large area; and furniſhed with ſeveral encircling earthen ramparts, appear to have poſſeſſed conſiderable ſtrength. This caſtle is ſaid to have been built by the ſons of Uchtred, prince of Merionethſhire, A. D. 1138. There is a handſome modern houſe on the hill on which the caſtle ſtands. The pariſh of Llanſtephan, which includes the hamlets of Aliſton, Laques, and Llan y Bre, contained, according to the return to parliament in 1801, a population of 974 perſons, inhabiting 205 houſes. Carliſle's Topographical Dictionary of Wales, 4to. 1811.

LLANTRISSANT, a borough and market-town in the hundred of Miſkin, and county of Glamorgan, South Wales, is ſituated near the ſummit of a cleft in one of the high hills which abound in the vale of Glamorgan. The only acceſs to it is by a ſteep circuitous road. One narrow irregular ſtreet, compoſed of poor habitations, makes up nearly the whole of this place. The church is a large Norman ſtructure. The cemetery affords a very extenſive proſpect. Here was an ancient Norman caſtle, of which but little now remains, except the fragment of a circular tower; the veſtiges of the outworks being nearly concealed by ſhrubs. Within the precincts of the caſtle are the town-hall and market-houſe, new buildings erected by the late earl of Bute. The borough is governed by a portreve, and unites with Cardiff, Swanſea, &c. in ſending one member to parliament. Llantriſſant is diſtant from Llandaff 10 miles, and from London 170: a weekly market is held on Friday, and three fairs annually. In the year 1801, the pariſh was returned as containing 376 houſes, inhabited by 1715 perſons. Barber's Tour in South Wales, 8vo.

LLANVYLLING, a market-town in the hundred to which it gives name, in the county of Montgomery, North Wales, is ſituated in a pleaſant valley, near the river Cane, 15 miles from Montgomery, and 186 from London. The town is neat, and many of the houſes are well built. It was firſt incorporated by Llewellyn ap Gryffydd, lord of Mecham and Mochnant, in the reign of Edward I.; and is governed by two bailiffs, choſen annually, who are juſtices of the peace during the time of office. Many Roman coins have been found here. Four fairs are held annually, and a weekly market on Tueſday. According to the population report of the year 1801, Llanvylling contained 444 houſes, and 1394 inhabitants. Pennant's Tour in Wales, and Skrine's Tour.

LLANWRTYD Wells, a medicinal ſpring of South Wales, in the county of Brecon; 12 miles W. of Builth.

LLANYDLOES, a market-town in the hundred of the ſame name, and county of Montgomery, North Wales, is pleaſantly ſituated near the bank of the river Severn, 13 miles from Newtown, and 180 from London. Several of the ſtreets are ſpacious, but the buildings are irregular, and chiefly of lath and plaſter. The church is a neat edifice, being ſupported by ſix arches, the pillars of which have capitals of palm-leaves, and are ſaid to have been brought from Cwmber Abbey. About the town are ſeveral very extenſive ſheep-walks; and a number of perſons are conſtantly employed in the neighbouring ſlate quarries. The pariſh conſiſts of the townſhips of Brithdir, Cil-Machen, Glynn-Hafren-Is-Coed, Manleodd, Morfodion, Treffin, and Yſtrad Dunod. The petty ſeſſions for the hundred are holden here. Llanydloes was formerly a contributory borough to Montgomery, but was diſfranchiſed with Pool and Llan-

Fyllin. The town however has ſtill the nominal appendages of a mayor, and his ſubordinate officers. A conſiderable manufactory of flannels is carried on here. Pennant, Evans, Bingley, and Skrine deſcribe this place and its neighbourhood in their reſpective tours in North Wales.

LLATA, a town of Peru, in the dioceſe of Lima; 90 miles from Lima.

LLAUGHARNE, Llaugharm, *Llacharn*, or *Laugharne*, a market-town, ſea-port, and pariſh, in the hundred of Derlis, Caermarthenſhire, Wales. The town is ſituated at the mouth of the river Coran, and is one of the moſt ſequeſtered towns in the principality. The church is a large handſome building, in very excellent condition. Towards the ſouth end of the town, and cloſe upon the bay of Caermarthen, ſtand the ruins of an old caſtle, which is ſaid to have been erected, or at leaſt re-built, by Guido de Brian, in the reign of Henry III. The remains of the gateway, which is covered with a profuſion of ivy, and various other parts of it, are ſtill in good preſervation. The corporation of Llaugharne conſiſts of a portreve, a recorder, an indefinite number of aldermen, two common attornies, four conſtables, and 76 burgeſſes. The market is held on Friday, and there are two fairs annually, but theſe are very inconſiderable. This was the birth-place of a celebrated political writer and divine, Dr. Joſiah Tucker, who died in 1799.

At a ſhort diſtance from the town are the veſtiges of a ruin, now called Roches caſtle. This building, according to tradition, was formerly a monaſtery, but when it was built, or by what order of monks, is wholly unknown. The pariſh church is ſaid anciently to have ſtood on the farm named Craſeland, *i. e.* Chriſt's land, but no traces of ſuch a building can now be diſcovered. In the year 1801, this town contained 1484 inhabitants.

LLECH, the Welſh name for a kind of monumental ſtone found in that country. See Pillar.

LLENDILAFAYA, a town of Spain, in the province of Aſturia; 8 miles S.W. of Orviedo.

LLERENA, a town of Spain, in the province of Eſtramadura, belonging to the knights of the order of St. Jago, by whom it was founded; 53 miles E. of Cordova. N. lat. 38° 7'. W. long. 5° 59'.—Alſo, a town of Mexico, in the province of Zacatecas; 80 miles N.N.W. of Zacatecas. N. lat. 23° 48'. W. long. 104° 46'.

LLIRIA. See Liria.

LLIVIA, a town of Spain, in Catalonia, in the Pyrenees, near the ſource of the Segre, anciently called "Julia Libyca;" 6 miles N.E. of Puycerda.

LLOBREGAT, a river of Spain, in Catalonia, which runs into the Mediterranean, about 9 miles W. from Barcelona.

LLOMSA, a town of the duchy of Warſaw, on the Narew; 70 miles N.N.E. of Warſaw.

LLORENTE don Bernardo, in *Biography*, a Spaniſh painter, who was in favour at the court of Philip V., and employed to paint the infant Don Felipe. From the proſpect of preferment this circumſtance held forth to him, he was diverted by a decided turn for ſolitude; which made him fly the court, and in the ſequel obtained for him the name of Pintor de las Paſtoras, the painter of ſhepherdeſſes, from the number of madonnas which he painted, arrayed in their garb, and ſurrounded by flocks. He died in 1757, at the age of 72.

LLORET, in *Geography*, a town of Spain, on the S.E. coaſt of Catalonia; 20 miles N.E. of Mataro. N. lat. 43° 42'. E. long. 4° 42'.

LLOWITSCH, a town of the duchy of Warſaw; 24 miles N.W. of Rava.

LLOYD, William, in *Biography*, an Engliſh prelate, was born at Tilehurſt, in Berkſhire, in 1627. His father, rector of his native place, took great pains in the education of his ſon, who repaid his attention by a moſt rapid progreſs in the learned languages. He was not quite twelve years of age when he was entered a ſtudent of Oriel-college, Oxford, whence he removed, in 1640, to a ſcholarſhip in Jeſus-college. He was ordained in 1656, and, after the reſtoration, he obtained, in a very ſhort time, conſiderable preferment in the church, till at length, in 1680, he was promoted to the ſee of St. Aſaph. In 1684, he publiſhed his "Hiſtory of the Government of the Church, as it was in Great Britain and Ireland, when they firſt received the Chriſtian Religion." In 1688, biſhop Lloyd was one of the ſix biſhops who, together with archbiſhop Sancroft, were committed to the Tower for preſenting a petition to king James II., againſt that prince's declaration for ſuſpending the laws in favour of the Papiſts, which the clergy were enjoined to read in the churches. Their triumphant acquittal is well known to our readers. About the cloſe of the ſame year, being known to concur very zealouſly in the revolution, he was made almoner to king William III., and, in 1692, was tranſlated to the ſee of Lichfield and Coventry. In 1699, he publiſhed "A Chronological Account of the Life of Pythagoras, and of other famous Men, his Contemporaries: with an Epiſtle to the Rev. Dr. Bentley, &c." In 1699, he was tranſlated to the biſhopric of Worceſter. Having, ſome time after this, been charged with an improper interference in the county election, he was diſmiſſed from the office of almoner. He died at Hartlebury-caſtle in the year 1717, when he had attained to the ninety-firſt year of his age. According to biſhop Burnet, Dr. Lloyd "was a great critic in the Greek and Latin authors, but chiefly in the ſcriptures. He was an exact hiſtorian, and the moſt punctual in matters of chronology. As much, however, as he was ſet on learning, he had never neglected his paſtoral care. He was a holy, humble, and patient man, ever ready to do good when he ſaw a proper opportunity; even his love of ſtudy did not divert him from that." He was author of a great number of publications, the titles of which are given in the Biographia Britannica: and he left ſeveral pieces behind him in an unfiniſhed ſtate; among theſe was "A Syſtem of Chronology," out of which his chaplain, Mr. Benjamin Marſhal, was ſaid to have compoſed his Chronological Tables. He was ſuppoſed to have had a principal ſhare in the "Series Chronologica Olympiadum, Iſthmiadum, Nemeadum, &c." publiſhed by his ſon at Oxford in 1700. He engaged biſhop Burnet to undertake his "Hiſtory of the Reformation," furniſhed him with a curious collection of facts and obſervations: and he aſſiſted Dr. Wilkins in compoſing his "Eſſay towards a real Character, and a philoſophical Language." Biog. Brit.

Lloyd, Robert, ſon of Dr. Peirſon Lloyd, was one of the uſhers of Weſtminſter-ſchool. We have already, under the article Churchill, refered to this unfortunate young man, who is known chiefly as an author, by a poem, entitled "The Actor," which not only exhibited proofs of great judgment in the ſubject he was treating of, but had alſo the merit of ſmooth verſification and ſtrength of poetry. He was ſome time at the univerſity of Cambridge, where he took the degree of M. A. After he quitted his place as uſher at Weſtminſter-ſchool, he relied entirely on his pen for ſubſiſtence: being of a thoughtleſs and very extravagant diſpoſition, he got deeply into debt, and was in conſequence thrown into the Fleet priſon, where he depended almoſt wholly on the bounty of his friend Churchill, whoſe kindneſs to him continued undiminiſhed during all his neceſſities. On the death of his benefactor, Mr. Lloyd ſunk into a ſtate of deſpondency, which put an end to his exiſtence in 1764. Mr. Wilkes ſays, that "Lloyd was mild and affable in private life, of gentle manners, and very engaging converſation. He was an excellent ſcholar, and an eaſy natural poet. His peculiar excellence was the dreſſing up an old thought in a new, neat, and trim manner. He was contented to ſcamper round the foot of Parnaſſus on his little Welſh poney, which ſeems never to have tired. He left the fury of the winged ſteed, and the daring heights of the ſacred mountain, to the ſublime genius of his friend Churchill." His works were publiſhed in 2 vols. 8vo. in 1774.

LLOYD, NICHOLAS, an Engliſh divine, who was rector of St. Mary Newington, Surrey, where he died in 1680, at the age of 49. He compiled an hiſtorical, geographical, and poetical dictionary, which was printed at Oxford in 1670, in folio, and again in 1695, in 4to.

LLOYD'S *Lake*, in *Geography*, a bay on the S. coaſt of Eaſt Florida. N. lat. 25° 18′. W. long. 80° 50′.

LLUCH MAYER, a town of the iſland of Majorca, ſituated in the middle of a large plain, at the end of which is a mountain ſtanding by itſelf, called La Randa. This town was built in the reign of James II. in the year 1300: the population amounts to about 3500 perſons. The ſtreets and houſes are very regularly built; it has one pariſh church, conſecrated to the archangel St. Michael.

LLULLA *and Chiloas*, a juriſdiction of the dioceſe of Truxillo, in South America, lying S. of Chachapayas, and E. of the Cordillera of the Andes; low, warm, and moiſt, and covered with woods, ſo that a great part of it is uninhabited. It borders on the river of Moyabamba, which, commencing its courſe from theſe ſouthern provinces of Peru, forms the river of the Amazons. The principal commodity of this country is tobacco, which, with a particular kind of almonds called "Andes," and a few other fruits natural to its climate, form the commerce carried on by this province with the others.

LLYN SAVADDAN, or *Savathan Pool*, a lake of South Wales, in Brecknockſhire; 4 miles E. of Brecknock. This lake is larger than any in Wales, except that of Bala, being two miles in length, and, in ſome places, one mile broad. The river Lunwy paſſes through this lake, and finds its way to the Wye, in a direction nearly due north. It is obſerved not to mix its waters with thoſe of the lake in its paſſage; and the ſeparation is underſtood to be ſo complete, that unleſs immediately after heavy ſtorms, the fiſh of the river are not found in the lake, nor thoſe of the lake in the river. The depth of Llynſavaddan is ſaid to be about thirteen fathoms. The ancient tradition of a city being drowned, ſo univerſally applied to ſuch bodies of water, is too trivial to deſerve further notice.

LLYWARCH AP LLYWELYN, in *Biography*, an ancient Welſh bard, who flouriſhed from about 1160 to 1220. Many of his pieces are in the Welſh Archaiology, and contain ſeveral hiſtorical notices of value.

LLYWELYN AP GRUFFYDD, the laſt ſovereign of Wales, who reigned from A.D. 1254, to 1282. He was a brave prince, and reſiſted the ambition of Edward I. king of England a long time, but he at laſt fell, and with him the independence of the Welſh as a diſtinct nation.

LLYWELYN SION, an eminent poet of Glamorgan, who collected the ſyſtem of Bardiſm, which is preſerved. He preſided at ſeveral meetings of the bards, and died in the year 1616.

LLYWELYN, THOMAS, a Welſh nonconformiſt divine of the Baptiſt denomination, was a native of Monmouthſhire, and died in 1796. He publiſhed a hiſtory of the different editions of the Welſh bible.

LO, ST. in *Geography*, a town of France, and principal place of a diſtrict, in the department of the Channel, of which it is the capital, ſeated on the Vére, ſurrounded with walls, and defended by a citadel, which has ſome manufactures of cloth, ſerges, and leather. The place contains 6987, and the canton 11,707 inhabitants, on a territory of 90 kiliometres, in 11 communes. N. lat. 49° 7′. W. long. 1° 1′.

LOACH, in *Ichthyology*, the Engliſh name of a fiſh, called alſo the *groundling*, and by the Germans the *ſmorle* or *ſmorling*. It is a ſpecies of the *Cobitis*. See COBITIS *Barbatula*.

LOAD, or LODE, in *Mining*. See LODE.

LOAD is alſo uſed for nine diſhes of ore, each diſh being about half a hundred weight.

LOAD, *Maſter*, among *Miners*. See MASTER-*load*.

LOAD, *Training a*. See TRAINING.

LOAD *Water-line*, in a *Ship*, is the deepeſt line of floatation, or when all her cargo is taken in.

LOADING. See CARGO and LADING.

LOADMANAGE, in *Maritime Affairs*: the hire is ſometimes ſo called, which the pilot of a ſhip receives of a maſter, for conducting a ſhip up the river, or into port.

LOADSTONE. See MAGNET.

LOADSTONE, *Floating*, an inſtrument invented and ſo called by Mr. Boyle, which he uſed to diſcover whether guineas or other coins were counterfeit, by putting the inſtrument, with the piece of coin to be tried and faſtened to the bottom of it, into a tall glaſs or other veſſel of water: marks being ſo made on the ſlender metalline pipe, which forms the upper part of the inſtrument, that the hollow ball which made the lower part of it, would ſink much lower, at leaſt two inches, if the coin be true gold than if it be not: and according as the water reaches to one or other of the aforeſaid marks, an eſtimate may be made, whether the piece of coin, if counterfeit, be made of tin, braſs, copper, ſilver, or lead. The inſtrument might be applied to any coins, either of gold or ſilver, provided that they were of any conſiderable bulk. Birch's Hiſt. of the Royal Society, vol. iii. p. 115.

LOAM, derived from the German word *leime*, and anciently ſignifying a viſcid earth, in *Natural Hiſtory*, a claſs of compound or mixed earths, compoſed of diſſimilar particles, hard, ſtiff, denſe, harſh, and rough to the touch, not eaſily ductile while moiſt, readily diffuſible in water, and uſually compoſed of ſand and a tough viſcid clay.

Hill comprehends under this claſs two genera. 1. The *thrauſtomicthes*; and, 2. The *gliſchromicthes*. The firſt are compoſed of ſand and a leſs viſcid clay, and are of a friable or crumbly nature; the ſecond are compoſed of ſand and a more viſcid clay, and are of a more tough and viſcid texture.

Da Coſta diſtinguiſhes them by their colour into black and white, which are not acted upon by acids; yellow loams, ſome of which are not acted upon by acids; and other alkaline, brown loams, ſome acted upon by acids, to which claſs belongs the Windſor loam, ſo well known and ſo much uſed for making bricks, building furnaces, lutes, &c. and others alkaline; and the green loams not acted upon by acids.

According to Woodward, loam conſiſts of clay, mixed with fine ſand, or of clay with a ſuperabundance of ſand; and Mr. Bergman, having analyſed ſome loam found in the neighbourhood of London, and conſidered as very excellent, found it to conſiſt of 87 *per cent.* of a reddiſh-grey ſand, as fine as meal, and 13 of argil. Suppoſing, therefore, clay to conſiſt, as it moſt frequently does, of 30 *per cent.* of argil, and 70 of fine ſand, we ſhall find, ſays Kirwan, that loam of the beſt kind contains an exceſs of ſand amounting to 17 *per cent.*; if the exceſs of ſand be greater, it will form what is called a *ſandy loam;* if ſmaller, *clayey loam.* Mr. Bergman found nothing calcareous in the loam; when it contains any, it ſo far inclines to the nature of marle, and this *marlaceous loam* may be either *ſandy* or *clayey*, according as the proportion above indicated is exceeded on either ſide. But loams moſt frequently contain alſo a portion of calx of iron, and this calx is more or leſs oxygenated; a circumſtance which produces a conſiderable variety in the colour, and probably alſo in the vegetative powers of this earth: if its proportion be conſiderable, *viz.* 4 or 5 *per cent.* they often contain alſo ſome proportion of vitriolic acid. The colour of loam frequently proceeds from that of the calces of iron contained in it, but more frequently from its ſandy part. Gravel, which is a coarſer ſort of ſand, either of a calcareous or ſiliceous nature, is often mixed with loams, and alſo pebbles, whence new diſtinctions ariſe of importance to agriculture. Kirwan's Elem. of Mineralogy, vol. i. See Mould and Soil.

Loam is alſo uſed for a ſort of mortar made of this earth, by tempering it with water, ſtraw, &c.

LOAMY Soil, in *Agriculture*, that ſort of ſoil into which loam enters in a conſiderable proportion. Theſe ſoils are diſtinguiſhed by many different names and colours. See Soil.

LOAN-Banks, or *Lending-houſes*, eſtabliſhments which may be traced to an ancient origin, formed and ſupported by humane perſons, with a view of lending money to the poor for a certain period, on pledges, without intereſt. Thus, we are told, the emperor Auguſtus converted into a fund the ſurplus of the money which aroſe to the ſtate from the confiſcated property of criminals, and lent ſums from it, without intereſt, to thoſe who could pledge value equal to double the amount. (Suet. Vit. Auguſti, cap. 41.) Tiberius alſo advanced a large capital, from which thoſe were ſupplied with money for three years, who could give ſecurity in lands equivalent to twice the value. (Suet. Vit. Tiberii, c. 48. Tacit. Annal. vi. 17. Dio Caſſius, c. viii. 21.) Alexander Severus reduced the intereſt of money by lending money at a low rate, and advancing ſums to the poor without intereſt to purchaſe lands, and agreeing to receive payment from the produce of them. (Æl. Lamprid. Vit. Alex. Severi, cap. 21.) Theſe examples of the ancients were followed in modern Italy. In order to collect money, the popes conferred upon thoſe who would contribute towards that object many fictitious advantages, which at any rate coſt them nothing. At firſt, money was lent to the poor for a certain time without intereſt, provided they could depoſit pledges of proper value. At length the pontiffs reſolved to allow the lending-houſes to receive intereſt, not for the whole capitals which they lent, but only for a part, merely that they might raiſe as much money as might be ſufficient to defray their expences. In proceſs of time, it was thought proper, for the purpoſe of their having ſufficient ſtock in hand, to give to thoſe who ſhould advance them money a moderate intereſt, which was prudently concealed by blending it with the unavoidable expences of the eſtabliſhment. The lending-houſes, therefore, gave and received intereſt. But in order to avoid the odious name, the intereſt that was received was ſaid to be "pro indemnitate;" and this is the expreſſion made uſe of in the papal bull. The pope declared the holy mountains of piety, as they were called, to be legal; and threatened thoſe with his vengeance who dared to entertain any farther doubts on the ſubject. All the cities now haſtened to eſtabliſh lending-houſes; and their example was at length followed in other countries. The origin of lending-houſes, in the ſtrict ſenſe of the term, is referred to the time of pope Pius II. or Paul II., who filled the papal chair from 1464 to 1471. The greater part of the lending-houſes in Italy was eſtabliſhed in the fifteenth and following centuries by certain Minorites. Notwithſtanding the manifeſt advantages with which lending-houſes were attended, and though many of them had been ſanctioned by the infallible court of Rome, many, but chiefly Dominicans, exclaimed againſt theſe inſtitutions, which they did not call *montes pietatis*, but *impietatis*. As this diſpute was revived with much warmth in the beginning of the 16th century, it was at length terminated by pope Leo X., who, in the council of the Lateran, declared by a particular bull, that lending-houſes were legal and uſeful; that all doubts to the contrary were ſinful; and that thoſe who ſhould write againſt them would be in a ſtate of excommunication. The council of Trent alſo, by a decree, acknowledged their legality, and confirmed them. See Mounts *of Piety*. See alſo Lombards and Bank.

LOANDA, in *Geography*, an iſland in the Atlantic, near the coaſt of Angola, about 12 miles long, and one wide, ſeparated from the continent by a narrow channel, which forms a good harbour. The ſoil does not produce grain; but fruits, ſuch as oranges, figs, &c. are plentiful. It contains ſeven or eight villages, and on the coaſt are found ſhell-fiſh, called "zimbi," uſed for money by the natives, like cowries in India. S. lat. 8° 50′.

Loanda, or *St. Paul de Loanda*, a ſea-port town of Africa, in the kingdom of Angola, the ſee of a biſhop, and capital of a fertile province called Loanda, in poſſeſſion of the Portugueſe; containing ſeveral churches and convents, and about 5000 inhabitants, of whom 1000 are whites, and the reſt blacks or mulattoes. The country abounds in cattle and ſheep; Indian corn, millet, manioc, and fruits. S. lat. 8° 53′. E. long. 13° 22′.

LOANGHILLY, a town of Africa, in Loango; the uſual burying place of the emperor; 10 miles S. of Loango.

LOANGO, a country or kingdom of Africa, ſituated on the W. coaſt towards the Atlantic, and bounded on the N. by Benin, on the E. by Anziko, and on the S. by Congo. Its climate is hotter, but not leſs healthy and pleaſant than that of Congo and Angola, nor is its ſoil leſs fertile. The inhabitants, inſtead of cultivating the land, content themſelves with bread and fiſh, and ſuch fruits, greens, and pulſe, as the ſoil naturally produces. Cocoas, oranges, and lemons are not much cultivated; but ſugar-canes, caſſia, and tobacco, as well as the palm, banana, cotton and pimento trees, grow here plentifully. They have alſo a great variety of roots, herbs, fruits, grain, and other vegetables, of which they make bread, and which they uſe for food. They have few quadrupeds for domeſtic uſe except goats and hogs, but poultry and various ſorts of game are abundant: among the wild beaſts they have the zebra, and a great number of elephants, whoſe teeth they exchange with the Europeans for iron. The natives, who are called Bramas, are tall, ſtout, and well formed, and though formerly cannibals, are of late much improved in their manners. They practiſe circumciſion, are addicted to trade among themſelves, and are friendly and hoſpitable in their mutual intercourſe. They are fond of females and jealous of their wives. Their dreſs conſiſts chiefly of cloth manufactured by themſelves; and they are fond of ornaments about their necks, legs, and wriſts, which they form of beads of coral, ivory, ſhells of a beautiful hue, chains of copper, tin, or iron, obtained from Europe. Polygamy is allowed among them; their rich men having 12 or more wives, and the poor not fewer than three. Of a Supreme Being, their notions are very imperfect and confuſed. Their worſhip is addreſſed to demons, domeſtic and rural; and to theſe they aſcribe great influence. To their monarchs they attribute a kind of ſupernatural and unlimited power. The foreign commerce of the country conſiſts chiefly in ſlaves; and they likewiſe ſell conſiderable quantities of ivory, tin, lead, iron, and copper. The kingdom of Loango, ſeparated from Congo, of which it was formerly a part, is divided into four principal provinces, *viz.* Lovangiri, Louango-Mongo, Kilongo, and Piri. The firſt is fertile and well inhabited; the ſecond, lying N.E. of the former, is ſpacious and productive, particularly of palm-trees, the oil of which they extract in great quantities; and the inhabitants employ themſelves in working a variety of linen and cloth; the third is a maritime province, and is the largeſt and the moſt populous of the four; its plains are extenſive and fertile, and they are ſheltered at a diſtance by ridges of high mountains; the trade of the inhabitants, who are rude and unpoliſhed, conſiſts in elephants' teeth; the laſt province, north of Kilongo and Louango-Mongo, is low and flat, but abounds with variety of fruits and other trees, and is well peopled and cultivated; the inhabitants are peaceable and ſtrangers to war. They have plenty of cattle, and of wild and tame fowl, and take great pleaſure in hunting. Their food is ſupplied by the game they take, and the milk of their cattle. In all theſe provinces there are many towns and villages.

Loango, a city of Africa, and capital of the above-mentioned country, ſituated on a river, which forms a bay at its mouth, about ſix miles from the coaſt of the Atlantic. The natives call it “Borai,” or “Boori.” It is very ſpacious and airy, as the houſes are not contiguous to one another. The ſtreets are wide and clean, and lined with palm-trees, bananas, and bacavas, which ſhelter the houſes both before and behind. The palace adjoins to a ſquare in the centre of the city, and of itſelf forms another ſquare, one and a half mile in compaſs, ſurrounded with a paliſado of ſtately palm-trees. Beſides the public buildings of which it conſiſts, it is occupied by the houſes of the king's women, ten in number, and each capable of accommodating ſeven or eight of them. At a ſmall diſtance is a market place, which ſupplies purchaſers every day with meal, poultry, fiſh, wine, corn and oil, as well as palm-cloth; and in the market-place is a famous temple and mokiſſo, or idol, called “Mokiſſo a Loango,” which has been held in great veneration both by the kings and their ſubjects. The houſes are of an oblong ſhape, flat in the middle part of the roof, and each houſe is fenced round with a hedge of palm-twigs, canes, or bulruſhes.

The bay of Loango, though upon the whole good, is incommoded by a bank on the N. ſide of its entrance, running half a league along the coaſt, and having not more than two and a half fathoms of water. The numerous and large rivers that flow from the continent, occaſion ſuch rapid and ſtrong currents towards the north during almoſt the whole year, that it is very difficult to weather them, and gain a ſouthern courſe. The only months in which they may be ſtemmed with ſafety are January, February, March, and April; during the other months of the year the currents flow ſo ſtrong, that even coaſters muſt keep at leaſt 10 or 12 leagues off the land. S. lat. 4° 40′. E. long. 10° 25′.

Loango, a river of Africa, which runs into the Atlantic, S. lat. 10° 30′.

LOANO, or Lovano, a town of Genoa, near the ſea; ſix miles S.S.W. of Finale.

LOANS, Government. See Stocks.

LOAR, or Loarre, in *Geography*, a town of Spain, in Aragon; 13 miles S. of Jaca.

LOARDEGA, a town of Hindooſtan, in Bahar; 40 miles S. of Palamow.

LOBARIA, in *Natural Hiſtory*, a genus of the Vermes molluſca claſs and order: Body lobate, convex above, flat below. There is only one ſpecies, *viz.* quadriloba, characterized as having a tail with four lobes. It is found in the northern ſeas.

LOBATUM Folium, in *Botany*, a leaf the outline of whoſe ſegments is curved. See Leaf.

LOBAU, in *Geography*, a town of Pruſſia, in the territory of Culm; 44 miles E. of Culm.

Lobau, or *Liebe*, one of the moſt ancient towns in the province of Upper Luſatia, containing two churches, three chapels, an hoſpital, and a Latin ſchool, and trading chiefly in linen and thread; 10 miles S.W. of Gorlitz. N. lat. 51° 7′. E. long. 14° 46′.

LOBB, Theophilus, in *Biography*, a phyſician of conſiderable reputation about the middle of the laſt century, practiſed his profeſſion in London, and left ſeveral works on medical topics. He died on the 19th of May, 1763, in the eighty-fifth year of his age. The following are the titles of his publications. “Treatiſe of the Small-pox,” London, 1731, 1748, 8vo.; which was tranſlated into French in 1749. “Rational Method of curing Fevers, deduced from the Structure of the Human Body,” ibid. 1734, 8vo.: in this work he adopted the doctrines of Boerhaave. “Medical Practice in curing Fevers,” ibid. 1735, 8vo. “A Practical Treatiſe on painful Diſtempers, with ſome effectual Methods of curing them,” ibid. 1739. “A Treatiſe on Solvents of the Stone, and on curing the Stone and the Gout by Aliments,” ibid. 1739. This work paſſed through ſeveral editions, and was tranſlated into Latin and French. The author conſidered the matter of urinary calculi and of gout as of an alkaline nature, and vegetable acids as the remedy. “Letters concerning the Plague and other contagious Diſtempers,” ibid. 1745. “A Compendium of the Practice of Phyſic,” ibid. 1747. Beſides theſe works, he was the author of ſeveral papers printed in the Gentleman's Magazine, and of one or more tracts on religious ſubjects in the latter part of his life. Eloy Dict. Hiſt. Gent. Mag.

LOBBY, in *Architecture*, is a ſmall hall or waiting-room: it is alſo an entrance into a principal apartment, where there is a conſiderable ſpace between that and a portico or veſtibule, and the length or dimenſions will not allow it to be conſidered as a veſtibule or an anti-room. See Antichamber.

Lobby, in a *Ship*, an apartment cloſe before the captain's cabin.

Lobby, in *Agriculture*, a ſort of narrow confined place, formed either by hedges and trees, or other kinds of fencing, near to the farm-yard, for the purpoſe of confining live-ſtock. It is obſerved by Mr. Marſhall, in his Minutes of Agriculture in the Midland Counties, that “every farmery ought to have a lobby and a croft appending to it, ſerving as a double fence; thereby preventing ſtock from running over, poaching, and injuring the farm; the latter for calves, a ſaddle horſe, and invalids. He found the conveniency of a lobby in Surrey, and the want of one in Norfolk, and in this diſtrict; he can foreſee the uſe of that which he is forming, with a ſcreen of planting; emboſoming the entire farmery, in ſuch a manner as to ſhelter it effectually from the north and eaſt winds."

LOBE, or Lobus, in *Anatomy*, an epithet applied to the more or leſs ſeparate parts, of which the glands of the body are compoſed. Thus we have lobes of the brain, lungs, liver, &c.

Lobe is alſo uſed for the tip of the ear; which is more fat and fleſhy than any other part thereof.

Du Laurent ſays, that the word *lobe*, in this laſt ſenſe, comes from the Greek, λωβεῖν, *to ſhame*, or *be aſhamed*; this part of the ear being ſaid to bluſh when the perſon is aſhamed.

Lobe is alſo uſed in ſpeaking of fruits and grains.

Thus the bean conſiſts of two equal parts, called lobes, which compoſe the body thereof, and are encompaſſed with the other ſkin. And all other grains, even the ſmalleſt, are divided, like the bean, into the two lobes, or equal parts; as Dr. Grew has ſhewn in his Anatomy of Plants. See Lobus.

LOBEDA, in *Geography*, a town of Germany in the principality of Eiſenach; three miles S.S.E. of Jena.

LOBEDIUN, a town of Ruſſia, in the government of Tambov; 100 miles W.N.W. of Tambov. N. lat. 53° 28′. E. long. 38° 50′.

LOBEGUN, a town of Weſtphalia, in the duchy of Magdeburg; 25 miles N. of Leipſic.

LOBEIRA, Vasco, in *Biography*, author of "Amadis of Gaul," was born at Porta about the middle of the fourteenth century. He was knighted upon the field of battle at Aljubarrota by king Joam I. in the year 1386, and died at Elvas, where he poſſeſſed a good eſtate. According to Mr. Southey nothing more has been collected by the Portugueſe biographers of Lobeira. It has been queſtioned whether he was the author of the Amadis de Gaul, and whether that poem was not written in France rather than in Portugal; to which the tranſlator replies, "Some weight muſt be allowed to the authority of the Portugueſe writers, who have all, with the exception of Cardoza, attributed it to Lobeira as an original production." "The romance," he farther adds, "is not older than Lobeira's age; for it refers to the Engliſh claim upon the crown of France, and repreſents Windſor as the moſt ſplendid court, and the king of England as the moſt powerful king in Chriſtendom. It was written in a country remote from England; for Windſor is called an iſland, and the adventurers who croſs from France make Briſtol their port. Many other ſuch inſtances of geographical ignorance could be mentioned; miſtakes which might eaſily be made by a Portugueſe, but not by a Frenchman. It was written in Portugal, for many of the names are Portugueſe. Better proofs of time and place cannot be required." Of the poem Mr. S. ſays; it may be ſafely affirmed that it contains nothing which, in the age in which it was written, would be regarded as impoſſible, ſcarcely any thing that would be thought exaggerated. The actions of Amadis, and the importance of a ſingle chief, would not appear incredible to a people who had then living among them their own hero, Nuno Alvares Pereira, whoſe military exploits were as extraordinary, and as important to his own character. To a nation who knew this man, and knew alſo that it was chiefly owing to his courage that they exiſted as a ſeparate people, the character of Amadis would not appear exaggerated. Amadis has been conſidered as the model of a perfect knight. "Truly," ſays ſir Philip Sidney, "I have known men, that even with reading Amadis de Gaul, which, God knows, wanteth much of a perfect poeſie, have found their hearts moved to the exerciſe of courteſy, liberality, and eſpecially courage."

LOBEL, or L'Obel, Matthias de, a botaniſt nearly contemporary with Cluſius, whoſe wooden cuts, for the moſt part, re-appeared in his works, was not, as ſome have thought, an Engliſhman, but born, in 1538, at Liſle in Flanders, where his father practiſed in the law. He acquired in his youth an ardent love of plants, and had good opportunities of gratifying his taſte, and advancing his knowledge, at Montpellier, where he ſtudied phyſic under the learned Rondelet, or Rondeletius. During his reſidence there, he found opportunities of making ſome botanical excurſions over the ſouth of France. At Narbonne he became acquainted with Pena, afterwards his fellow labourer in the *Adverſaria*, the firſt edition of which was publiſhed, in ſmall folio, at London, in 1570, and dedicated to queen Elizabeth. The few cuts diſperſed through this volume are moſtly original, but inferior in ſtyle and accuracy, as well as in ſize, to thoſe of Cluſius. Before the publication of the *Adverſaria*, our author had extended his travels to Switzerland, the Tyrol, ſome parts of Germany and Italy; had ſettled as a phyſician at Antwerp, afterwards at Delft; and had been appointed phyſician to the illuſtrious William prince of Orange, and to the ſtates of Holland. Dr. Pulteney has not been able to aſcertain the time of Lobel's removal to England, but juſtly concludes it to have been before 1750; indeed, moſt probably, ſome years earlier, as he mentions in this edition of the *Adverſaria*, p. 92, having long ago received from Dr. Turner ſeeds of the Sea Kale, *Crambe maritima*, of which he there exhibits an indifferent cut, mentioning it as a plant whoſe flowery tops might be eaten, though much inferior to the cultivated kinds of the ſame tribe. It appears by this, that the young ſprouts, now known to be ſo excellent for the table, had not then been tried.

The aim of the authors of the *Adverſaria* was to inveſtigate the botany and *materia medica* of the ancients, and eſpecially of Dioſcorides. They therefore frequently criticiſe Matthiolus, the moſt celebrated commentator of the Greek writer, for it is ſcarcely poſſible for different people to purſue this intricate and obſcure path long without diſagreement. Indeed half a ſcore commentators on the plants of Dioſcorides might all exerciſe their ingenuity, in moſt caſes, with equal ſkill, without any body being able to decide which of them was neareſt the truth. The *Adverſaria* was reprinted at Antwerp in 1576, the dedication being, of courſe, there ſuppreſſed. New title-pages had been printed to help the ſale of the original, in 1571 and 1572. Some copies of the Antwerp impreſſion appear to have been made up into a new edition at London in 1605, an ample *Pharmacopeia*, the foundation of which was from Rondeletius, being prefixed, and an appendix to the *Adverſaria* ſubjoined. This volume is dedicated to Edward lord Zouch, whom Lobel had attended, on his embaſſy to Denmark, in 1592, and he calls himſelf, in the title, botaniſt to king James I. Dr. Pulteney obſerves, after Haller, that this work exhibits ſome traces of a natural diſtribution of plants, inſomuch at leaſt as they are thrown together into a number of tribes or orders, according to their habits or flowers; but this is done without any remarks, and with ſo little preciſion, that it can only be ſaid the method of Lobel is better than that of Dodonæus, in which there is no conſiſtent principle at all. His work is much more valuable for the various remarks which it contains, and for the accounts of new plants, diſcovered by himſelf in England or elſewhere. On the ſubject of Britiſh natives indeed, Ray accuſes him of having made ſeveral miſtakes, from having truſted too much to his memory.

The *Stirpium Hiſtoria* of this author, a volume in ſmall folio ſimilar to his *Adverſaria*, was publiſhed at Antwerp in 1576. This is much leſs copious in matter, the pages being moſtly occupied with wooden cuts, which are thoſe of Cluſius, borrowed for the preſent occaſion by the printer, Plantin. An impreſſion of theſe cuts, of an oblong ſhape, was ſtruck off, with names only, in 1581, and another in 1591. Linnæus poſſeſſed both. This publication is in very general uſe, and well known by the title of Lobel's *Icones*. It is, when complete, accompanied by an index in ſeven languages.

Lobel ſeems to have had a very large work in contemplation, which he intended to call *Stirpium Illuſtrationes*. This he did not live to complete. A fragment of it was publiſhed in quarto, without plates, by Dr. W. How, in 1655, making 170 pages, beſides a cauſtic preface of the author, aimed chiefly at Gerarde, whom he doubtleſs comprehends among the "*ſordidi pharmacarii*," charged with robbing the moſt experienced phyſicians of their honours. The body of the work is interſperſed with notes of Dr. How's againſt Parkinſon, who is ſaid to have made diſhoneſt uſe, in his *Theatrum Botanicum*, of ſome papers of Lobel, that fell into his hands. It muſt be allowed that ſuch authors are juſtly cenſured for tranſlating and interweaving deſcriptions, remarks, and places of growth, from foreign works, which apply to the plants of other countries. This fault is not diſſimilar from what we have cenſured in a more modern writer; ſee LIGHTFOOT, and the botanical article FLORA. But the ſtyle of Lobel's preface is properly reprobated by Dr. Pulteney, who blames him for this groſs abuſe of Gerarde after his death, though he had formerly on every occaſion extolled him. The botanical contents of this fragment are, however, very honourable to Lobel, for the number of new plants therein mentioned.

Our author laboured to an advanced age in the purſuit of his favourite ſtudy, and procured from his correſpondents abroad, many new plants for the gardens of his friends. He had the ſuperintendance of a garden at Hackney, cultivated at the expence of lord Zouch; and appears to have reſided, in the decline of life, at Highgate, where he had a daughter, married to a Mr. James Coel. His wife is recorded as having aſſiſted him in his botanical reſearches. He died in 1616, aged 78. Lobel's works. Haller's Bibl. Bot. Pulteney's Sketches.

LOBEL, a ſtrolling, blind, fiddling, Bohemian Jew, the firſt maſter, on the violin, of the celebrated Benda, firſt violin to Frederic II. king of Pruſſia, during the whole reign of that muſical prince. See BENDA, and Burney's German Tour, vol. ii.

LOBELIA, in *Botany*, ſo called in honour of Matthias de Lobel; ſee that article. The plant to which Plumier originally applied the name, is now the *Scævola* of Linnæus. When the latter, at the ſuggeſtion of Jacquin, diſcovered that he and other botaniſts had confounded, under this original *Lobelia*, a vaſt number of ſpecies generically diſtinct from it, but which were then become much better known than itſelf by the name in queſtion, he judged it much leſs inconvenient to keep this name for them, and to give the genus of Plumier a new one. It is hoped the ſame meaſure would be adopted, ſhould any botaniſt aſcertain the original *Magnolia* of Plumier, to be really diſtinct in generic characters from all the other ſpecies ſo called, of which there is ſaid to be ſome ſuſpicion.—Linn. Gen. 456. Schreb. 596. Willd. Sp. Pl. v. 1. 937. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 242. Ait. Hort. Kew. ed. 2. v. 1. 356. Juſſ. 165. Lamarck Illuſtr. t. 724. (Rapuntium; Tourn. t. 51. Gærtn. t. 30.)—Claſs and order, *Pentandria Monogynia*. (Syngeneſia Monogamia; Linn.) Nat. Ord. *Campanaceæ*, Linn. Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, ſurrounding the germen, in five deep, nearly equal, withering ſegments; the two ſuperior ones moſt directed upwards. *Cor.* of one petal, irregular, ſlightly ringent; tube cylindrical, longer than the calyx, divided lengthwiſe at the upper ſide; limb in five deep lanceolate ſegments, of which the two uppermoſt are ſmalleſt, moſt reflexed, and moſt deeply ſeparated, conſtituting the upper lip; the three lowermoſt more ſpreading, and generally largeſt. *Stam.* Filaments five, awl-ſhaped, the length of the tube of the corolla, united upwards; anthers united into an oblong, ſomewhat oblique and curved, cylinder, ſeparating into five parts at the baſe. *Piſt.* Germen more than half inferior, pointed; ſtyle cylindrical, the length of the ſtamens; ſtigma obtuſe, hiſpid. *Peric.* Capſule ovate, or roundiſh, of two or three cells, and two or three valves, burſting at the top, encompaſſed by the calyx; the partitions contrary to the valves. *Seeds* numerous, minute, ſmooth. *Receptacle* conical.

Eſſ. Ch. Calyx in five ſegments, crowning the germen. Corolla of one petal, irregular. Anthers cohering, incurved. Capſule half inferior, of two or three cells.

So much uncertainty attends the characters of ſome plants which have been referred to *Lobelia*, that we can hardly gueſs with any degree of correctneſs at the number of ſpecies. The 14th edition of the *Syſtema Vegetabilium* exhibits the lateſt view that Linnæus or his ſon took of the genus, and there 42 ſpecies are enumerated, of which however the 21ſt, *lævigata*, and 25th, *ſurinamenſis*, are one and the ſame, and *tenella*, No. 40, which is *parvifolia* (not *parviflora*) of Bergius, is *Lightfootia oxycoccoides*; ſee LIGHTFOOTIA. Three others, *Phyteuma*, *bulboſa*, and *volubilis*, go along with *Cyphia*, *cardamines*, and *inciſa*, of Thunberg's Prod. 39, to form the genus CYPHIA, Berg. Cap. 173. Willd. Sp. Pl. v. 1. 952. Ait. Hort. Kew. ed. 2. v. 1. 362, of which we have ſpoken in its place, and which perhaps, when we conſider its having five diſtinct petals, with linear and ſtraight, as well as ſeparate, anthers, may be allowed to conſtitute a tolerably good, though not a very natural, genus. Willdenow, retaining this genus, has ſtill 48 *Lobeliæ*, diſpoſed in three, not very correct, ſections, of each of which we ſhall mention a few examples. Two ſpecies only are natives of Britain.

Sect. 1. *Leaves entire.*

L. *Dortmanna*. Water Lobelia. Linn. Sp. Pl. 1318. Engl. Bot. t. 140. Fl. Dan. t. 39. (Dortmanna lacuſtris, floribus ſparſis pendulis; Rudb. Act. Upſ. for 1720. 97. f. 2. Gladiolus lacuſtris; Ger. em. 105.)—Leaves linear, entire, of two parallel cells. Stem nearly naked.—Found in the clear ſhallow parts of lakes, in the colder parts of Europe, growing in the pure gravelly bottom, and raiſing the flowering part of its ſtem only above the ſurface. The *root* is perennial, compoſed of numerous, long, white, ſimple fibres. *Herb* ſmooth, milky when wounded. Radical *leaves* numerous, entirely immerſed, linear, recurved, nearly cylindrical, though flattiſh on the upper ſide, obtuſe, two or three inches long, very remarkable for conſiſting internally of two cavities, ſeparated by a longitudinal partition. *Stem* ſolitary, erect, round, hollow, almoſt leafleſs, bearing a looſe cluſter of pendulous blue *flowers* in July and Auguſt, often overflowed by ſudden floods. Cluſius received this plant from a Mr. Dortmann, and has repreſented it in his *Curæ Poſteriores*, 40; but the cut, reprinted in Johnſon's edition of Gerarde, is juſtly criticiſed by Rudbeck; for the germen is repreſented ſuperior, the ſtamens totally erroneouſly, and the corolla by no means well.

Sect. 2. *Stem erect. Leaves cut or ſerrated.*

L. *Tupa.* Willow-leaved Lobelia. Linn. Sp. Pl. 1318. (Rapuntium ſpicatum, foliis acutis, vulgò *Tupa;* Feuill. It. v. 2. 739. t. 29.)—Leaves decurrent, lanceolate, finely ſerrated. Cluſter ſpiked. Stem hollow. Feuillée gathered this plant on the mountains of Chili, in 37 degrees ſouth latitude; (not 65, as in Bot. Mag. 1325.) He ſpeaks of it as one of the moſt active of poiſons, the ſmell of the flowers cauſing ſevere vomitings, and the milk of the plant, if by any accident it touches the eyes, occaſioning blindneſs. The *root* is a foot and a half long, apparently perennial. *Stem* as tall as a man, hollow, five-ſided, terminating in a ſpike of large, blood-red, ſtalked flowers, with a lanceolate *bractea* at the baſe of each partial ſtalk. *Leaves* decurrent for the ſpace of 2½ inches, the reſt of their length, about ſeven inches, elliptic-lanceolate, acute, finely ſerrated, minutely downy; reticulated with veins beneath. Feuillée deſcribes the ſerratures, but does not figure them.

L. *gigantea.* Gigantic Lobelia. Sims in Curt. Mag. t. 1325. (L. Tupa; Dryand. in Ait. Hort. Kew. ed. 2. v. 1. 357.)—Leaves ſeſſile, lanceolate, finely ſerrated. Flowers axillary, ſolitary, ſtalked. Stem ſhrubby, ſolid.—Our ſpecimen of this plant was gathered by Mr. Menzies near Valparayſo in Chili, in latitude 33½ ſouth, whence Dr. Brandt is ſaid alſo to have brought ſeeds to Meſſrs. Lee and Kennedy, in whoſe conſervatory the ſhrubby *ſtem* is 15 or 16 feet high, ſolid, and round. *Leaves* ſeſſile, lanceolate, more or leſs ſerrated, ſcarcely reticulated beneath. *Flowers* dull orange, on ſimple, ſolitary, axillary ſtalks, much ſhorter than the leaves. Theſe characters have, in our opinion, juſtified Dr. Sims in making it diſtinct from the laſt, to which it ſeems moreover inferior in virulence.

L. *aſſurgens.* Purple Jamaica Lobelia. Linn. Sp. Pl. 1321. Andr. Repoſ. t. 553.—Leaves elliptic-lanceolate, tapering at both ends, ſharply toothed, ſomewhat decurrent. Cluſter compound, terminal, downy.—Native of Jamaica. It flowers in the latter part of ſummer in our ſtoves, making a handſome appearance, though its purpliſh colour is leſs ſtriking than the ſcarlet of the following.

L. *cardinalis.* Scarlet Lobelia. Linn. Sp. Pl. 1320. Curt. Mag. t. 320.—Leaves broadly-lanceolate, ſerrated. Spike terminal; the flowers turned one way.—Native of North America. Hardy in our gardens, in a ſtrong moiſt ſoil, flowering in Auguſt and September. The *root* is perennial. *Stems* three feet high, leafy. *Flowers* of a moiſt rich and vivid ſcarlet.

L. *urens.* Acrid Lobelia. Linn. Sp. Pl. 1321. Curt. Lond. faſc. 6. t. 63. Engl. Bot. t. 953.—Stem nearly erect. Lower leaves obovate, finely toothed; upper lanceolate, ſerrated. Flowers racemoſe.—Native of France, Spain, and ſome few parts of Devonſhire, on gravelly buſhy commons. This is perennial, flowering in Auguſt and September. Its habit is ſlender, delicate, and ſmooth. *Stem* 18 to 24 inches high, milky. *Leaves* ſcattered. *Flowers* ſmall, blue, numerous, in long weak cluſters. Segments of the *calyx* briſtle-ſhaped, rough, as long as the tube of the flower.

Sect. 3. *Stem moſtly decumbent. Leaves ſomewhat cut.*

L. *Laurentia.* Italian Annual Lobelia. Linn. Sp. Pl. 1321. (Laurentia annua minima, flore cæruleo; Mich. Gen. 18. t. 14.)—Stem proſtrate, branched. Leaves lanceolate-oval, crenate. Stalks ſolitary, axillary, ſingle-flowered, very long.—Native of Italy. A little delicate annual ſpecies, ſent to Kew in 1778, by M. Thouin. It bloſſomed in the green-houſe in July. The *flowers* are blue, very minute.

L. *ſetacea.* Briſtle-ſtalked Lobelia. Sm. Prodr. Fl. Græc. Sibth. v. 1. 145. Fl. Græc. ined. t. 221. (L. tenella; Bivon. Cent. 1. 53. t. 2.)—Radical leaves ſpatulate, wavy; thoſe of the ſtem briſtle-ſhaped. Stems perfectly ſimple, ſingle-flowered, erect.—Native of boggy places in Crete, Cyprus, and Sicily. *Root* annual. *Leaves* ſpatulate, on long ſlender radical ſtalks, obtuſe, wavy, ſmooth, ſomewhat like thoſe of a daiſy. The little ſlender *ſtems* bear two ſmall briſtle-like leaves, and one elegant blue flower. The ſtems appear to be erect, but on account of the cloſe affinity of the preſent ſpecies to *L. Laurentia,* they cannot be disjoined. They are indeed confounded by Willdenow, and by Boccone in his t. 27, where both are well drawn, as one ſpecies. Our *ſetacea* is Rapuntium creticum minimum, bellidis folio, flore maculato; Tourn. Cor. 9.

L. *lutea.* Yellow Lobelia. Linn. Sp. Pl. 1322. Curt. Mag. t. 1319.—Stems aſcending. Leaves lanceolate, ſerrated. Flowers reverſed, in ſhort ſpikes.—Native of the Cape of Good Hope. It flowers here in the green-houſe, and is remarkable for its golden *flowers,* whoſe poſition, as Dr. Sims obſerves, is reverſed, their tube very ſhort, and the poſture of their two ſmaller ſegments, arched over the ſtamens, very peculiar.

Numerous new ſpecies of *Lobelia* are to be added to Willdenow's liſt, from the diſcoveries in New Holland. Theſe are uſually of a ſmooth delicate habit. See Labillardiere, t. 71—74, and Brown's *Prodromus,* v. 1. 562. The latter defines 20 ſpecies from that country, none of them in Willdenow.

Lobelia, in *Gardening,* comprehends plants of the herbaceous and under-ſhrubby perennial kind, of which the ſpecies uſually cultivated are the ſcarlet lobelia, or cardinal's flower (L. cardinalis;) the blue lobelia, or cardinal's flower (L. ſiphilitica;) the long-flowered lobelia (L. longiflora;) the pine-leaved lobelia (L. pinifolia;) and the bladder-podded lobelia (L. inflata.)

Method of Culture.—The firſt and ſecond kinds may be increaſed by ſeed, cuttings of their ſtalks, and parting the roots. The ſeeds ſhould be ſown in autumn, or early in ſpring, in a warm border, or in pots or boxes, ſo as to be moved to different ſituations in different ſeaſons, to have ſhelter from froſt, and ſhade from the mid-day ſun in ſummer. Thoſe ſown in autumn generally come up more freely the following ſpring than thoſe which are ſown in that ſeaſon. They ſhould have ſhelter in hard froſts, either under a frame or awning of mats, but be fully expoſed in mild weather, giving occaſional waterings in the ſpring and ſummer. When the plants have attained two or three inches growth, they ſhould he pricked out in ſeparate ſmall pots of rich earth, giving water, and placing them in the ſhade till freſh rooted, repeating the waterings occaſionally in hot dry weather, and ſhifting them into larger pots as they may require; in winter moving them into a frame to have occaſional ſhelter from inclement weather; and in the ſpring following ſome of them may be turned out into the full ground about March, when they will flower the enſuing ſummer. Some ſhould alſo be retained in pots to be moved under ſhelter in winter, as a reſerve in caſe thoſe in the open air ſhould be killed by the froſt.

And as the plants generally flower in the greateſt perfection the firſt and ſecond year of their blowing, it is proper to raiſe a new ſupply of them every year or two in order to have them flower in the utmoſt perfection every year.

Where the ſecond mode is in uſe, the cuttings of the young ſtalks ſhould be divided into lengths of five or ſix inches, and be planted in an eaſterly border, two parts deep, being covered down with hand-glaſſes, and watered occaſionally. They moſtly emit roots, and form young plants in a month or ſix weeks, when the glaſſes ſhould be taken away, and the plants managed as the others.

And theſe hardy ſorts ſometimes afford off-ſets from their ſides at bottom, which may be ſeparated in autumn, and potted for young plants, being managed as the ſeedlings.

Each of the three laſt ſorts may alſo be raiſed by ſeeds procured from abroad, which ſhould be ſown in pots of light ſandy earth in the autumn, and plunged in the bark-bed; and when the plants are three inches high, planted in ſeparate pots, being replunged in the bark-bed, giving water and occaſional ſhade till they are freſh rooted. They muſt remain conſtantly in the hot-houſe, and have frequent moderate waterings given them.

The firſt two ſorts have a fine appearance in the borders and clumps of pleaſure-grounds, where they will ſucceed when protected in winter from froſts and other injuries.

And all the tender ſorts afford a fine variety in hot-houſe collections.

Lobelia *Siphilitica*, *Blue Lobelia*, or *Cardinal Flower*, in the *Materia Medica*, is a native of Virginia, and flowers from Auguſt till October. Every part of the plant abounds with a milky juice, and has a rank ſmell. The root, which is the part preſcribed for medicinal uſe, in taſte reſembles tobacco, and is apt to excite vomiting. It derived the appellation of *ſiphilitica* from its efficacy in the cure of ſyphilis, according to the experience of the North American Indians, who conſidered it as a ſpecific in that diſeaſe, and who long kept it a ſecret. But the ſecret was purchaſed by ſir William Johnſon, and has been ſince publiſhed by different authors. The method of employing this medicine is ſtated as follows: a decoction is made of a handful of the roots in three meaſures of water. Of this half a meaſure is taken in the morning faſting, and repeated in the evening; and the doſe is gradually increaſed till its purgative effects become too violent, when the decoction is to be intermitted for a day or two, and then renewed till a perfect cure is effected. During the uſe of this medicine, a proper regimen is to be enjoined, and the ulcers are alſo to be frequently waſhed with the decoction, or if deep and foul, to be ſprinkled with the powder of the inner bark of the New Jerſey tea-tree (Ceanothus Americanus.) Although the plant thus uſed is ſaid to cure the diſeaſe in a very ſhort time, yet the antiſyphilitic powers of the lobelia have not been confirmed by any inſtances of European practice. Woodv. Med. Bot.

LOBENSTEIN, in *Geography*, a town of Saxony, and chief place of a lordſhip, on the Lemnitz, in the county of Reuſſen; 26 miles N. of Bayreuth. N. lat. 50° 21′. E. long. 11° 50′.

LOBERA, a town of Spain, in Aragon; 20 miles W.S.W. of Jaca.

LOBES, a town of Bohemia, in the circle of Boleſlaw; 9 miles W.N.W. of Jung-Buntzel.—Alſo, one of the ſmaller Canary iſlands, between Lancerotta and Fortaventura. N. lat. 28° 50′. W. long. 13° 40′.

Lobes *of the Ear, Boring of.* To bore or perforate the lobes of the ears, you muſt firſt of all mark the place with a ſpot of ink. About the middle is generally the beſt ſituation for the aperture. The lobe of the ear is to be extended with the left fore-finger and thumb, and the perforation made exactly where the dot is, with a large common ſewing needle. The ring being now introduced, and gently moved about a few times every day until the margin of the puncture is healed, will hinder the little hole from becoming impervious. See Heiſter's Surgery, vol. ii. p. 5.

LOBINEAU, Guy-Alexis, in *Biography*, was born at Rennes in 1666, entered among the Benedictines of St. Maur in his ſeventeenth year, and devoted his life and talents to ſtudy. He died in the year 1727. His principal works are "L'Hiſtoire de Bretagne," two vols. folio, to which he gave the finiſhing hand, it having been compoſed by Father le Gallois: "L'Hiſtoire de Deux Conquètes d'Eſpagne par les Maures," which is a tranſlation from the Spaniſh, and is probably little more than a romance. "Hiſtoire de Paris," 5 vols. folio: this work was begun and much advanced by father Felibien, and put into the hands of Lobineau to finiſh. "L'Hiſtoire des Saints de Bretagne." He tranſlated the "Stratagems of Polyænus" from the Greek, and made verſions of ſome of Ariſtophanes' comedies. Moreri.

LOBITH, in *Geography*, a town of the duchy of Cleves; 5 miles N.W. of Emmerick.

LOBKOWITZ, Prince, in *Biography*, deſerves well to be remembered among illuſtrious dilettanti in muſic. He was in England at the ſame time as the myſterious count St. Germaine, from 1746 to 1748; and from congenial taſtes in muſic, they were ſeldom aſunder. This prince, who was uncle to the charming and accompliſhed madame Thune at Vienna, was no leſs remarkable for his muſical talents, than the beauty and dignity of his perſon. We have ſeen and heard at Vienna many of his muſical compoſitions, chiefly for the German flute, which, from their correctneſs, would not have diſgraced an eminent profeſſor. The termination of this gallant prince's career was melancholy; after diſtinguiſhing himſelf in the army, as well as by his accompliſhments and good taſte in the fine arts, he loſt his faculties; and was ſeized with a dark and gloomy deſpondency, in which he lingered during the remainder of his miſerable exiſtence.

Lobkowitz, Boleslas de Hassenstein, *Baron de*, a Bohemian nobleman and man of letters. After travelling into various countries, and bearing arms with reputation, he embraced the eccleſiaſtical ſtate, and was employed in public affairs. He died in 1510. His poems were firſt printed at Prague in 1563, and again in 1570. Moreri.

LOBLOLLO Bay, in *Geography*, a bay of the iſland of Antigua, on the W. coaſt.

LOBLOLLY-Bay, in *Botany*. See Gordonia.

Loblolly, a ſea-faring diſh, otherwiſe called *burgoo*.

LOBLOSOW, in *Geography*, a town of Poland, in Red Ruſſia; 36 miles S.E. of Halicz.

LOBO, Jerome, in *Biography*, a Jeſuit miſſionary, born at Liſbon in 1593, entered among the Jeſuits in his ſixteenth year, and in 1622 he went out as one of their miſſionaries to the Eaſt Indies. After paſſing ſome time at Goa, he ſailed to the coaſt of Africa, and penetrated into Abyſſinia, where he reſided ſome years, ſubject to much danger and many hardſhips and ſufferings: on his return he was ſhipwrecked and narrowly eſcaped deſtruction. He promoted the intereſt of the Abyſſinian miſſion at Madrid and Rome, and, notwithſtanding the calamities to which he had been ſubjected, he took a ſecond voyage to the Indies. He returned to Liſbon in 1658, and was made rector of the college of Coimbra, where he died in 1678, at the age of 84. He was author of "An Hiſtorical Account of Abyſſinia," containing much curious and valuable information. It was tranſlated from the Portugueſe language into the French by the Abbè le Grand, with additions, which tranſlation was abridged by Dr. Samuel Johnſon. Moreri.

Lobo, Rodriquez Francis, a Portugueſe poet, was born at Eſtramadura. He was author of a comedy called "Euphroſyne," which is a great favourite among his countrymen. He was likewiſe the author of a folio volume of poems printed in 1721. Moreri.

Lobo, in *Geography*, a town on the S. coaſt of the iſland of Luçon. N. lat. 13° 40′. E. long. 121° 10′.

LOBON, a town of Spain, in the province of Eſtramadura; 13 miles W. of Merida.

LOBOS, a ſmall iſland in the Atlantic, near the coaſt of Africa. N. lat. 21° 20′.—Alſo, a ſmall iſland at the mouth of La Plata river; 15 miles S.W. of Cape St. Maria. N. lat. 35°.—Alſo, a ſmall iſland in the gulf of Mexico, on the coaſt of Guaſteca. N. lat. 22° 28′.—Alſo, iſlands in the Pacific ocean, near the coaſt of Peru, ſurrounded with rocks; about twelve miles from each other, in S. lat. 6° 25′ and 6° 45′. They are alſo called "Sea-Wolves," or "Seals' iſlands."—Alſo, a cluſter of ſmall iſlands in the South Pacific ocean, near the coaſt of Chili. S. lat. 52° 20′.

Lobos *Key*, or *Seal Key*, a ſmall iſland among the Bahamas. N. lat. 22° 45′. W. long. 77° 44′.

LOBRES, a town of Spain, in the province of Grenada; 7 miles N. of Motril.

LOBS, in *Mining*, are ſteps that aſcend or deſcend within the mines, as ſtairs up to and down from a chamber.

LOBSKOI, Pelanskoi, in *Geography*, a town of Ruſſia, in the government of Olonetz, near the lake Sig; 52 miles W.N.W. of Povenetz.

LOBSTADT, a town of Saxony, in the circle of Leipzig; 10 miles S.S.E. of Leipzig.

LOBSTER, in *Zoology*, a ſpecies of the ſquilla, according to ſome writers; but in the Linnæan ſyſtem a ſpecies of the cancer. See Cancer *Gammarus*.

LOBULUS, in *Anatomy*, a diminutive from *lobus*, is a ſmall lobe, and denotes more minute diviſions of glandular bodies, than thoſe which form lobes: as, for example, the lobuli of the lungs. Lobulus auris is that part of the external ear which is pierced for ear-rings. (See Ear and Lobes.) Lobulus Spigelii is a ſmall portion of the liver. See Liver.

Lobulus, in *Botany*, a little lobe, a term ſuggeſted by Dr. Smith, for what has uſually, but erroneouſly, been called the auricle, in ſome ſpecies of *Jungermannia*; ſee that article.

LOBURG, in *Geography*, a town in the duchy of Magdeburg; 22 miles E. of Magdeburg.

LOBUS, in *Botany*, a lobe, a principal diviſion of a leaf, the margins of which are in ſome degree rounded. The term is alſo uſed for the diviſions of the petals, or any other ſuitable part. A capſule is ſometimes ſaid to be lobed, there being ſcarcely any other way of deſcribing, in Engliſh, a tricoccous or tetracoccous fruit.

LOCAGNANO, in *Geography*, a town of the iſland of Corſica; 12 miles N. of Baſtia.

LOCAL, ſomething ſuppoſed to be tied or annexed to ſome particular place.

Thus, in *Law*, a thing is ſaid to be local, *i. e.* annexed or fixed to the freehold. An action of treſpaſs for battery, &c. is tranſitory, not local; that is, it is not neceſſary, that the place where battery was committed ſhould be ſet down as material in the declaration; or if it be ſet down, the defendant cannot traverſe it, by ſaying, he did not commit the battery in the place mentioned in the declaration, and ſo avoid the action.

Local, *Choſe*. See Chose.

Local *Colour*, a technical term in the art of *Painting*, wherein, however, it has two meanings. The one is the actual colour of an object intended for imitation; the other alludes to that colour in conjunction with the ſituation the object which poſſeſſes it fills in a picture; wherein it muſt be more or leſs ſubject to ſhadows, and the regulations of aerial perſpective: which latter diminiſhes the force of colours according to their diſtance from the eye, by the intervention of that of the atmoſphere.

It is a difficult but a neceſſary part of the art to maintain local colours in objects and yet throw them into ſhade, and ſtill more to ſupport it in the gradations from light to dark. A degree of cool colour intervenes in nature, the admixture of which in the ſubſtances uſed in painting too often deſtroys the local or real colour, ſo that painters have often had recourſe to their ſhadow-colour alone, and by mixing that with the poſitive colour, truſt to its effect for harmony, and omit the greater delicacies of nature. But Titian, Vandyke, Correggio, and ſir J. Reynolds, ventured to attempt the full ſupport of the colour of the body, and ſucceeded, particularly the two latter, whom the artiſt will do well to ſtudy on this head.

Local *Cuſtoms*, are thoſe peculiar to ſome lordſhip, or other diſtrict, and not agreeable to the general cuſtoms of the country. See Custom.

Local, or *Artificial Memory*. See Memory.

Local *Motion*. See Motion.

Local *Problem*, in *Mathematics*, is ſuch an one as is capable of an infinite number of different ſolutions; becauſe the point that is to ſolve it, may be indifferently taken within a certain extent; *e. gr.* any where in ſuch a line within ſuch a plane figure, &c. which is called a *geometrical locus*.

A local problem may be either *ſimple*, as when the point ſought is in a right line; *plane*, as when the point ſought is in the circumference of a circle; *ſolid*, as when the point required is in the circumference of a conic ſection; or *ſurſolid*, as when the point is in the perimeter of a line of a *higher kind*, as the geometers call it.

Local *Treſpaſs*, in *Law*. See Trespass.

LOCANA, in *Geography*, a town of France, in the department of the Dora, on the Orco, in a valley, called the "Valley of Locana;" 21 miles S. of Aoſta.

LOCARNO, one of the Italian bailliages of Switzerland, ceded to the Swiſs cantons by Maximilian Sforza, duke of Milan, in the year 1512, and governed by a bailiff whoſe office continues two years; about 15 miles in length and about 12 in breadth. It is ſituated on the N.W. coaſt of the lake Maggiore, is fertile in grain and fruits, and contains 49 pariſhes, and 30,000 inhabitants. By the peace of Luneville it was ceded to the Ciſalpine republic, now the kingdom of Italy.

Locarno, the capital of the bailliage of the ſame name, a ſmall, open, well-built, market town, agreeably ſituated in a fertile plain, near the N.W. border of Locarno, or Maggiore lake, and containing about 1500 inhabitants. Part of the town is built on piazzas in form of a creſcent with two wings; in front is a row of trees and the public walk; the old part of the town is dirty, and the ſtreets narrow. It contains three convents, and a ſmall Franciſcan monaſtery, perched on a rock overhanging the valley, and commanding a ſuperb view of the lake and its magnificent boundaries. The canopy in the church of the Capuchins deſerves mention on account of its beautiful execution; it is of ſtraw-work, and almoſt rivals velvet and gold fringe. Locarno was once ſituated on the lake, and had a port capable of receiving large barks: at preſent it ſtands at the diſtance of a quarter of a mile; a circumſtance which is owing to the accumulation of ſand brought down by the torrent Maggia. The environs of the town abound in wine, fruit, and paſtures. It is now annexed to and included in the department of Verbano. N. lat. 45° 59′. E. long. 8° 35′.

Locarno, *Lake*, or *Lago Maggiore*. See Lake.

LOCATE, a town of Italy, in the department of the Olona; 6 miles S. of Milan.

LOCATELLI, Pietro, in *Biography*, a native of Bergamo, and one of the greateſt performers on the violin in Europe, during the early part of the laſt century; but no leſs remarkable for caprice in his compoſitions, than for execution and a full tone in his performance. He publiſhed twelve grand concertos for violins, and much muſic for other inſtruments, at Amſterdam, where he reſided from 1744 to 1764. Few could play his concertos but himſelf; yet there was "more method in his madneſs," than in that of Vivaldi; ſometimes a ſolidity and good taſte, particularly in his ſlow movements, not inferior to the adagios of Tartini. In 1772, we were very much ſurpriſed to find the blind organiſt and Carilloneur Potholt at Amſterdam poſſeſſed of a taſte ſo delicate and modern in a place where little other muſic was encouraged or liſtened to than "the jingling of bells and of ducats," till that excellent performer told us that Locatelli, the famous player on the violin, who had lived many years in that city, and died in 1764, uſed to give him inſtructions, and to encourage his muſical ſtudies by allowing him the advantage of being always a hearer at his public concerts as well as private performances. This, in ſome meaſure, helped us to account for his taſte and fancy; for Locatelli was poſſeſſed of a great deal of both; and though he delighted in capricious difficulties, which his hand could as eaſily execute as his head conceive; yet he had a fund of knowledge in the principles of harmony, that rendered ſuch wild flights agreeable, as, in leſs ſkilful hands, would have been inſupportable. Foreigners who travelled through Holland, and were curious to hear Locatelli perform, were previouſly appriſed, that the remuneration expected was fixed at two golden ducats for himſelf, and a ſilver ducat to the perſon who accompanied him.

LOCATION, in the *Civil Law*, an act by which any thing is let out, on rent.

The ſecond title of the nineteenth book of the Digeſt is on the ſubject of location and conduction. Location and conduction are relative terms, and are uſed as well for the action of him that lets, as for that of him who takes on that letting.

Location, *Tacit*, is, when the perſon who takes, continues on the premiſes beyond the term of his leaſe; which by the civil law he is allowed to do, at leaſt for the ſpace of a year, on the ſame terms.

LOCCO, in *Geography*, a town of Naples, in Abruzzo Citra, on the Peſcara; 10 miles N. of Sulmona.

LOCH, in the *Materia Medica*, a name given by Avicenna and others to the gum lac. They call it alſo *keikem* and *kenkem*, and are too apt to confound it with the cancanum, ſandarach, and other gums, with which they made their ſeveral ſorts of varniſh.

Loch, or *Lohoch*, in *Pharmacy*, a compoſition of a middle conſiſtence between a ſyrup and a ſoft electuary; chiefly uſed for diſeaſes of the lungs.

The word is originally Arabic; but continues ſtill in uſe among the apothecaries.

The Latins call it *linctus*, and the Greeks εκλειγμα, becauſe the manner of taking it is by licking.

Loch, in *Geography*, a name given in Scotland to a lake and alſo to a bay.

Loch *Alarich*, a lake in the county of Perth; 10 miles S. of George's town:—L. *Alſarrig*, a lake in the county of Inverneſs; 14 miles N.W. of Fort Auguſtus:—L. *Anacat*, a lake in the county of Perth; 11 miles S.E. of George's town:—L. *Anſtronmun*, a lake in the county of Perth; four miles N.W. of George's town:—L. *Archeig*, a lake in the county of Inverneſs, 10 miles long and one broad; 12 miles N. of Fort William:—L. *Aven*, a lake in the S.W. part of Bamffshire; 21 miles S. of Inveraven:—L. *Awe*, a lake in the county of Argyle, 30 miles long, and from a mile to two wide, ſhaded with many ſmall woody iſles, one of which bears the ruins of a monaſtery, and another thoſe of an ancient fortreſs, the reſidence of the Campbells of Lochawe, afterwards dukes of Argyle:—L. *Baa*, a lake on the iſland of Mull, communicating with loch Nagaul to the N.:—L. *Barnera*, a lake or inlet of the ſea, on the N.W. coaſt of the iſland of Lewis; 11 miles W. of Stornaway:—L. *Broom*, a bay on the W. coaſt of Scotland, ſeven miles long and two broad, communicating with L. *More*, its mouth being in N. lat. 57° 56′. W. long. 5° 13′:—*Little L. Broom*, a bay on the W. coaſt of Scotland, eight miles long and one broad; eight miles S.E. of Udrigil Head, N. lat. 57° 52′. W. long. 5° 16′:—L. *Broom*, a town of Scotland, in the county of Roſs, at the S. end of L. Broom lake; 25 miles W.N.W. of Dingwall:—L. *Caſtle Semple*, a lake in the county of Renfrew; ſix miles S.W. of Paiſley:—L. *Catherine*, a lake in the S.W. part of the county of Perth, about ſix miles in length; 20 miles W.S.W. of Crieff:—L. *Dalreach*, a lake in the county of Ayr; 10 miles S.S.E. of Ayr:—L. *Damb*, a lake in the county of Perth; ſeven miles S. of George's town:—L. *Dee*, a lake in the county of Kircudbright; 12 miles N.W. of New Galloway:—L. *Derculoch*, a lake of Perth; ſeven miles S. of Blair Athol:—L. *Dirantadlin*, a lake in the counties of Argyle and Perth; ſeven miles N.W. of George's town:—L. *Doine*, a lake of Perth; 20 miles W.S.W. of Crieff:—L. *Druinard*, a lake on the N.W. ſide of the iſland of Ilay:—L. *Drumelly*, a lake of Perth; ſeven miles N.W. of Coupar:—L. *Duntelchah*, a lake in the county of Inverneſs; 20 miles N.E. of Fort Auguſtus:—L. *Eil*, a lake of Inverneſs, eight miles long and one broad, near Fort William:—L. *Enoch*, a lake in the county of Kircudbright; 14 miles N.W. of New Galloway:—L. *Ericht*, a lake in the county of Inverneſs, 12 miles long and half a mile wide; four miles N. of George's town:—L. *Erriboll*, a capacious and ſafe bay on the N. coaſt of Scotland; three miles W. of Whitenhead, its mouth being in N. lat. 58° 32′. W. long. 4° 29′:—L. *Erſey*, a lake in Arran iſland; five miles N.W. of Brodick:—L. *Eſſan*, a lake of Perth; 18 miles S. of George's town:—L. *Etive*, a bay on the W. coaſt of Scotland, 20 miles long and about one broad; 15 miles N. of Inverary, N. lat. 36° 26′. W. long. 5° 5′:—L. *Fainiſh*, a lake in the N.W. part of the county of Roſs; 16 miles W. of Dingwall:—L. *Fine*, a bay in the county of Argyle, 34 miles long, and from one to four and ſix broad, extending from about ſix miles N.E. of Inverary to the river Clyde; its mouth being in N. lat. 55° 50′. W. long. 5° 8′:—L. *Fintrakin*, a lake in the county of Dumfries; ſeven miles N.W. of Lochmaben:—L. *Fitty*, a lake in the county of Fife; three miles N.N.E. of Dumfermline:—L. *Frenchy*, a lake of Perth; nine miles N. of Crieff:—L. *Garry*, a lake of Perth; nine miles N.E. of George's town:—L. *Garvie*, a lake in the county of Roſs; 10 miles W. of Dingwall:—L. *Goyle*, a lake which branches off to the N.W. from loch Long, N. lat. 56° 8′. W. long. 5°:—L. *Heck*, a lake in the county of Argyle, between loch Long and loch Fine:—L. *Inver*, a lake in the county of Kircudbright; five miles N. of New Galloway:—L. *Kenmoor*, a lake at the union of the Ken and Dee, five miles long and half a mile wide:—L. *Kingsmoor*, a lake in the county of Selkirk; 11 miles S.S.W. of Selkirk:—L. *Laggan*, a lake of Inverneſs, eight miles long and half a mile wide; 10 miles S.E. of Fort Auguſtus:—L. *Lawerſton*, a lake in the county of Kincardine; nine miles N.N.E. of Stonehaven:—L. *Leadmore*, a lake in the county of Roſs; 24 miles W.N.W. of Dornoch:—L. *Lee*, a lake in the county of Angus; 11 miles N.N.W. of Brechin:—L. *Leven*, a bay on the E. coaſt of Scotland, in Inverneſs, 10 miles long and half a mile wide; nine miles S. of Fort William, its mouth being in N. lat. 56° 40'. W. long. 5° 20':—Alſo, a lake of the ſame name, ſituated in the county of Kinroſs. Though inferior to loch Lomond, not only in extent but in beauty of ſcenery, ſtill it muſt be allowed to preſent to the eye a noble expanſe of water, interſperſed with a variety of fruitful and pleaſant iſlands. This lake varies in ſize conſiderably at different ſeaſons. It is bounded on the eaſt by the Lomond-hills, on the ſouth by the hill of Balneartie, and on the weſt by the plain of Kinroſs. The trout of loch Leven are of a large ſize, and bear a ſtrong reſemblance, both in taſte and appearance, to the ſalmon. They are regularly brought to the Edinburgh markets, where they find a ready ſale, being conſidered extremely delicate. The red colour of their fleſh undoubtedly ariſes from their feeding chiefly on a ſmall ſhell fiſh of a very deep tinge, which abounds in the bottom of the loch. A variety of other fiſh are likewiſe caught here. Eels are particularly plentiful. Theſe, in the month of September, generally migrate towards the ſea in great numbers by the channel of the Leven river, which takes its riſe from the lake. It is remarkable that they never proceed in their migration except during the night.

Loch Leven deſerves particular attention on account of the many diſtinguiſhed remains of antiquity which either adorn its iſlands or its banks. The ruins of the caſtle of loch Leven are placed upon an iſland nearly in the centre of the loch. Its original foundation is unknown, for though tradition ſays it was built by Congal, ſon of Dongart, king of the Picts, yet very little credit can be given to this account. The firſt notice taken of it in hiſtory occurs in the year 1334, when it was beſieged by ſir John de Sterling, an Engliſh officer, commanding a party of Scots who had joined the Engliſh army. But what principally renders this caſtle famous in Scottiſh hiſtory, is the confinement here of the unfortunate queen Mary, by the confederate lords to whom ſhe ſurrendered herſelf priſoner, after having parted with Bothwell at Carberry. Being placed in the cuſtody of the wife of Douglas of loch Leven, a woman of rude manners, and an inveterate enemy to the queen, ſhe ſuffered all the miſeries of a rigorous captivity. In this caſtle ſhe remained for ſeveral months almoſt forgotten, till the haughty conduct of the regent having eſtranged the minds of many of the confederates, they reſolved to reſcue her and themſelves from his tyranny and oppreſſion. With this view ſeveral attempts were made to effect her releaſe, but all of them were rendered abortive by the vigilance of her keeper. Love, however, at laſt prevailed over every obſtacle, Mary, conſcious of poſſeſſing thoſe bewitching charms which ſeldom fail in ſecuring a deep intereſt in the breaſt of ambitious youth, reſolved to employ them in captivating the heart of George Douglas, her keeper's brother. She treated him with the moſt marked diſtinction, and even allowed him to entertain the moſt daring hopes. The temptation was too great to be reſiſted. Having engaged ſome accomplices, they contrived to ſecure the keys one evening, when the family were at their devotions, and opening the gates, allowed the queen and her lover to eſcape by a boat which lay ready to receive them. As ſoon as they reached the ſhore the queen was met with the utmoſt joy by lord Seaton and ſir James Hamilton, with whom ſhe immediately fled to Nidrie, in Eaſt Lothian.

On another, and the largeſt iſland in the lake, the priory founded by Brudo, the laſt but one of the Pictiſh kings, formerly ſtood. Its ruins are ſtill viſible. Portmeak-monaſtery was ſituated on the eaſtern bank of the loch; only a few fragments of it remain. To the eaſt are the ruins of the ancient tower or caſtle of Arnot, which was poſſeſſed by a family of that name for upwards of 600 years. Forſyth's Beauties of Scotland:—L. *Leys*, a lake in the county of Kincardine; 11 miles N.W. of Stonehaven:—L. *Lochy*, a lake of Inverneſs, between Fort William and Fort Auguſtus, 10 miles long, and more than one wide, communicating with loch Eil, loch Linnhe, and loch Archeig:—L. *Lomond*, a lake in the county of Argyle, 17 miles long, and from one to four wide, with ſeveral ſmall iſlands on the broadeſt part, which are ſuppoſed to form part of the Grampian chain, that terminates here on the W. communicating with the Clyde, by a river which joins the Clyde at Dumbarton; 24 miles W. of Stirling; its S. extremity being in N. lat. 56° 3'. W. long. 4° 30'. At the time of the earthquake in Liſbon in the year 1755, the waters of this lake were agitated in a ſingular manner (ſee LOMOND):—L. *Loyal*, a lake in the county of Sutherland, five miles long; two miles S. of Tongue:—L. *Luichart*, a lake in the county of Roſs; 11 miles W. of Dingwall:—L. *Lydoch*, a lake of Perth; five miles W. of George's town:—L. *Lyon*, a lake of Perth; 10 miles S.W. of George's town:—L. *Maddy*, a lake of Inverneſs; five miles long, and half a mile wide; 17 miles N.N.W. of Fort Auguſtus:—L. *Mahaake*, a lake of Perth; five miles N.W. of Dumblane:—L. *Monteith*, a lake in the vicinity of L. Lomond, about five miles in circumference, with two woody iſles, one preſenting the ruins of a monaſtery, the other thoſe of a caſtle of the old earls of Monteith:—L. *Merk*, a lake of Perth; ſeven miles N. of Blair Athol:—L. *Mickly*, a lake of Inverneſs; 13 miles N.N.E. of Fort Auguſtus:—L. *Milford*, or *Melfort*, a ſafe road or harbour, on the W. coaſt of Scotland, much frequented by herrings. N. lat. 56° 16'. W. long. 5° 32':—L. *Moan*, a lake in the N.W. part of the county of Kircudbright; 18 miles N.W. of New Galloway:—L. *Mochrum*, a lake in the county of Wigton; ſeven miles W. of Wigton:—L. *Monar*, a lake in the county of Roſs; ſix miles long and half a mile wide:—L. *Moorn*, a lake in the N.W. part of the county of Roſs; nine miles N of Dingwall:—L. *Moy*, a lake of Inverneſs, near a town of the ſame name; nine miles S.E. of Inverneſs:—L. *Naver*, a lake in the N. part of Scotland, 12 miles in circumference; 28 miles N.N.W. of Dornoch:—L. *Nell*, a lake of Argyle; 17 miles N.W. of Inverary:—L. *Neſs*, a lake of Inverneſs; 22 miles long and one broad, between Fort Auguſtus and the Frith of Murray, into which its waters are diſcharged. This lake was affected at the time of the earthquake at Liſbon: on account of its great depth, from 60 to 135 fathoms, it never freezes:—L. *Oich*, a lake of Inverneſs; four miles long, and a quarter of a mile wide, communicating with loch Neſs; four miles S.W. of Fort Auguſtus:—L. *Oochan*, a lake of Inverneſs; nine miles W.N.W. of George's town:—L. *Orr*, a lake in the county of Fife; ſix miles N.E. of Dumfermline:—L. *Orent*, a lake in the county of Caithneſs; ſix miles S. of Thurſo:—L. *Paatoch*, a lake of Inverneſs; 12 miles N. of George's town:—L. *Quich*, a lake of Inverneſs; 16 miles N. of Fort William:—L. *Rannoch*, a lake of Perth; about eight miles long, E. of George's town:—L. *Rutton*, a lake in Kircudbright; four miles S.E. of Dumfries:—L. *Shin*, a lake in the N. part of the county of Sutherland; 12 miles long and 1½ wide; 13 miles W.N.W. of Dornoch:—L. *Skene*, a lake in the county of Aberdeen; five miles S. of Kintore:—L. *Skiach*, a lake of Perth; ſix miles N.W. of Dunkeld:—L. *Tay*, a lake of Perth, which is a grand and beautiful expanſe of water, of ſuch length as rather to reſemble a noble river, abounding with fiſh, and terminating in an iſland, on which are ſeen the ruins of a priory; having in its eaſtern extremity the capital manſion and plantations of the earl of Braidalben; 24 miles N.W. of Perth:—L. *Tollie*, a lake in Argyle; 11 miles N.N.E. of Glenorchy:—L. *Treig*, a lake of Inverneſs; 14 miles E. of Fort William:—L. *Tumel*, a lake of Perth; five miles S. of Blair Athol:—L. *Turret*, a lake of Perth; five miles N.N.W. of Crieff:—L. *Vack*, a lake of Perth; three miles S.S.W. of Blair Athol:—L. *Valican*, a lake of Perth; ſix miles E. of Blair Athol:—L. *Voil*, a lake of Perth; 17 miles W. of Crieff:—L. *Vrine*, a lake in the county of Roſs; ſix miles long, and half a mile wide; 25 miles W.N.W. of Dingwall:—L. *Vrotachan*, a lake in the S.W. part of Aberdeenſhire; ſeven miles S. of Caſtleton of Braemar:—L. *Uſſie*, a lake of Roſs; two miles W. of Dingwall:—L. *Watten*, a lake in Caithneſs; ſeven miles W. of Wick:—L. *Yeben*, a lake on the W. coaſt of Scotland, on the N. ſide of Loch Terridon.

LOCHABER, a diſtrict of Scotland, in the county of Inverneſs; about 40 miles long and 25 broad, of which the chief place is Fort William. This is one of the moſt dreary, mountainous, and barren diſtricts in Scotland, thinly inhabited, with the houſes wretched. The chief produce is black cattle, with very large flocks of ſheep. Here prince Charles erected his ſtandard in 1745, upon his landing from France, with ſeven officers, and arms for 2000 men.

LOCHE, or *Sea*-LOCHE, a name uſed in ſome parts of England for the *muſtela*, called in other places, particularly in Cornwall, the *whiſtle-fiſh*. See GADUS *Muſtela*.

LOCHEM, in *Geography*, a town of Holland, in the department of Guelderland, on the Borkel; 10 miles E. of Zutphen.

LOCHER MOSS, a moraſs of Scotland, in the county of Dumfries; 10 miles long and three broad, which muſt have been formerly a foreſt, on account of the oak trees that are dug up in it; and as canoes and anchors have been alſo found here, it muſt have been once covered with ſea.

LOCHES, a town of France, and principal place of a diſtrict, in the department of the Indre and Loire; 21 miles S.S.E. of Tours. The place contains 4342, and the canton 14,701 inhabitants, on a territory of 385 kiliometres, in 18 communes. The caſtle, ſeated on a rock in this town, was formerly an important fortification. It had four ranges of ſubterraneous paſſages, running over one another, in the uppermoſt of which, Louis Sforza, duke of Milan, was impriſoned for 10 years, and where he died. Its large tower contains two cages or moveable rooms, with ſtrong oak gates, covered with iron; and in one of theſe cardinal Balve, biſhop of Angers, was confined by Lewis XII. At a convent near the town, an edict was paſſed in 1576, in favour of the Proteſtants; but it was ſoon after violated by the queen regent, Catherine de Medicis. N. lat. 47° 7'. E. long. 0° 34'.

LOCHIA, in *Midwifery*, a diſcharge of blood from the uterus of women, occurring after the expulſion of the placenta, and continuing four, five, or more days. See LABOUR, *Natural*.

LOCHIAL FEVERS, a term uſed by medical writers to expreſs ſuch fevers as ariſe from ſuppreſſions or imminutions of the lochial diſcharges in lying-in women, or from any other irregularities during the time of that diſcharge.

LOCHMABEN, in *Geography*, a town and royal borough, ſituated in the county of Dumfries, and diſtrict of Annandale, Scotland. It is ſuppoſed to have derived its name from the number of ſmall lochs in its vicinity. This borough, according to tradition, received its original charter from king Robert Bruce, whoſe paternal eſtate was the lordſhip of Annandale. It is certain at leaſt, that this monarch beſtowed upon it a conſiderable portion of lands from his own property. The oldeſt charter extant is a writ of *novodamus*, by James VI., dated 16th July, 1612; which aſſigns as a reaſon for the renewal, the deſtruction of the town and its records by the Engliſh, during ſome of their inroads. Lochmaben has undoubtedly been formerly of more importance than at preſent. The borough-roods and town commouty are very extenſive, and for the moſt part fenced off at a very trifling annual rent. The government of the town is veſted in a provoſt, three bailies, a dean of guild, a treaſurer, and nine common-council-men. Coarſe linen is the ſtaple production of this place; 60,000 yards being annually manufactured here and in the neighbourhood for the Engliſh market. The coal uſed for fuel is brought chiefly from Cumberland. Annan, Dumfries, Kirkcudbright, Sanquhar, and this town, join in ſending one member to parliament.

The pariſh of Lochmaben extends about ten miles along the banks of the Annan, which poſſeſſes a very valuable ſalmon fiſhery, almoſt contiguous to the town. Several ſmaller ſtreams flow into this river, all of which are abundantly ſupplied with trout. In the largeſt of the lochs, which preſent a truly beautiful ſheet of water, a great variety of fiſh are caught. The fiſhermen aſſert, that there are 15 or 16 different kinds fit for the table. Among theſe is one called the vendiſe, or vendace, ſome ſay from Vendois in France, as being brought thence by one of the Jameſes. This ſtory, however, does not ſeem very probable, as it is found by experience, that this fiſh dies the inſtant it is touched. Beſides, it has in vain been attempted to tranſport it to other lochs in the neighbourhood. The vendiſe is about the ſize of a herring, and reſembles it both in external appearance and anatomical ſtructure. In taſte and flavour it is extremely delicate, ſo that it is reckoned among the moſt delicious fiſh that ſwims. It lies generally in the deepeſt parts of the loch, and is caught with the net.

Upon a peninſula which ſtretches out into this loch ſtands a caſtle, originally built by Robert de Bruce, the firſt of that name who ſwayed the Scottiſh ſceptre. It was a place of great ſtrength previous to the introduction of fire-arms, and could ſtill be made ſo, if its fortifications were raiſed anew according to the principles of modern warfare. The original buildings of the caſtle ſeem to have occupied about an acre of ground. The walls were twelve feet in diameter. Three ditches ſurround the whole at different diſtances. The area contained within the outermoſt wall may be about 13 acres. The inner one paſſes through a part of the caſtle, within which there was a place for the ſecurity of the boats, either from the effects of the weather or an enemy. While Scotland was a diſtinct kingdom from England, this fort was the frontier garriſon againſt Carliſle. The marquis of Annandale, among his other titles, aſſumes that of conſtable, or hereditary keeper of the caſtle of Lochmaben. To this office was attached a ſalary of 300*l*. Scotch, along with the fiſhings of the lochs. For the maintenance of the troops compoſing the garriſon, the government had likewiſe what was called a *laird-a-mart*, or *lardiner* *mart* cow, which was one of the beſt fat cows from every pariſh in Annandale. Very little of the caſtle now remains, it having been completely pillaged of its materials for the conſtruction and ornament of many of the houſes in the neighbourhood.

Between this caſtle and the Kirk-lochs, cloſe to the town, are the veſtiges of another fort of more ancient date. Tradition reports that the ſtones were removed to aſſiſt in building another caſtle, probably that in the loch. The ſituation of this caſtle is fine, and commands a beautiful proſpect over an extenſive plain. It was originally the reſidence of the Bruce family, before they aſcended the throne of Scotland. It is ſaid that king Robert I. was born here.

Contiguous to the caſtle firſt mentioned, on the banks of the Annan, lies a large tract of fertile land, called the Four-towns, as comprehending four populous villages. Theſe lands were originally granted by one of the Scottiſh monarchs to his houſhold ſervants, and the property of each being very ſmall, bare poſſeſſion was declared a ſufficient title. When any part of this property is transferred, it is only neceſſary to mark the tranſaction in the books of the lord of the barony. In meaſuring the lands of this diſtrict, an ell, called the barony ell, is made uſe of, which contains 42 inches, whereas the common ell of the country is only 38 inches.

Lochmaben and its vicinity derive no ſmall degree of celebrity, as the ſcene of ſome of the heroic actions of the renowned ſir William Wallace. According to the population report of 1801, this pariſh contained 499 houſes, and 2053 inhabitants.

LOCHNEV, a town of Sweden, in the province of Smaland; 60 miles N. of Calmar.

LOCHSTETT, a town of Pruſſia, in the province of Smaland, near which are the ruins of a caſtle, in which was a dungeon, that ſerved for a priſon; four miles N. of Pillau.

LOCHVITZE, a town of Ruſſia, in the government of Tchernigov, on the Suſa; 96 miles S.E. of Tchernigov. N. lat. 50° 20′. E. long. 28° 14′.

LOCIS COMMUNIBUS. See COMMUNIBUS.

LOCK, MATTHEW, in *Biography*, organiſt and compoſer to his majeſty Charles II., was a native of Exeter, and a choriſter in the cathedral of that city, while William Wake was organiſt there. He had afterwards inſtructions in muſic from Edward Gibbons, and had ſo much diſtinguiſhed himſelf as a profeſſor of abilities, that we are told in the continuation of ſir Richard Baker's chronicle, he was appointed to compoſe the muſic for the public entry of the king at the reſtoration, and captain Henry Cook for his coronation.

But he ſeems firſt to have appeared as an author in 1657, during the interregnum, by the publication of his "little conſort of three parts for viols or violins, conſiſting of pavans, ayres, corants, ſarabands, in two ſeveral varieties, the firſt twenty of which are for two trebles and a baſe."

Some of his compoſitions appear in the ſecond part of John Playford's continuation of Hilton's "Catch that catch can," in 1667. Of which publication, the ſecond part contains "Dialogues, Glees, Ayres, and Ballads, of two, three, and four voices," among which we find the moſt pleaſing of Lock's compoſitions; "Never trouble thyſelf about times or their turnings," a glee for three voices.

Lock was the firſt who attempted dramatic muſic for the Engliſh ſtage, if we except the maſques that were performed at court, and at the houſes of the nobility, in the time of Charles I., and during the reign of Charles II. When muſical dramas were firſt attempted, which Dryden calls heroic plays and dramatic operas, Lock was employed to ſet moſt of them; "Circe," written by ſir William Davenant's ſon, Dr. Davenant, was ſet by Banniſter; but the *ſemi-operas*, as they were called, the Tempeſt, Macbeth, and Pſyche, tranſlated from the French of Moliere by Shadwell, were ſet to muſic by Lock. The Tempeſt and Pſyche were performed in 1673, with muſic, dancing, and ſplendid ſcenes, but not printed till 1675, when it was publiſhed with the following title: "The Engliſh Opera; or the vocal Muſic in Pſyche, with the inſtrumental therein intermixed. To which is adjoined the inſtrumental Muſic in the Tempeſt. By Mathew Lock, compoſer in ordinary to his Majeſty, and Organiſt to the Queen." This publication is dedicated to James duke of Monmouth. There is a preface of ſome length by the compoſer, Matthew Lock, which, like his muſic, is rough and nervous, exactly correſponding with the idea which is generated of his private character, by the peruſal of his controverſy with Salmon, and the ſight of his picture in the muſic-ſchool at Oxford. It is written with that natural petulance which probably gave birth to moſt of the quarrels in which he was involved. He begins with a complaint of the tendency of his brother muſicians "to peck and carp at other men's conceptions, how mean ſoever may be their own. And expecting to fall under the laſh of ſome ſoft-headed or hard-hearted compoſer," he ſets about removing "the few blocks at which they may take occaſion to ſtumble," with a degree of indignation that implies an iraſcible ſpirit under no great governance. The firſt objection which he thinks likely to be made, is to the word opera, to which he anſwers, that it is a word borrowed from the Italian, who by it diſtinguiſhed this kind of drama from their comedies, which, after a plan is laid, is ſpoken extempore; whereas this is not only deſigned, but written with art and induſtry; and afterwards ſet to ſuitable muſic. In which idea he has produced the following compoſitions, which, for the moſt part, are "in their nature ſoft, eaſy, and, as far as his abilities could reach, agreeable to the deſign of the poet. For in them there is ballad to ſingle air, counterpoint, recitative, fugue, canon, and chromatic muſic, which variety, without vanity be it ſaid, was never in court or theatre, till now preſented, in this nation." He confeſſes, however, that ſomething had been attempted before in this way of compoſition, but more by himſelf than any other. And adds, "that the author of the drama prudently conſidering, that though Italy was and is the great academy of the world for muſic and this ſpecies of entertainment, yet as this piece was to be performed in England, which is entitled to no ſuch praiſe, he mixed it with interlocutor, as more proper to our genius."

He concludes his peeviſh preface by confeſſing, that "the inſtrumental muſic before and between the acts, and the entries in the acts of Pſyche, were omitted by the conſent of the author, Signor Gio. Baptiſta Draghi; and that the tunes of the entries and dances in the Tempeſt (the dances being changed) were omitted for the ſame reaſon."

Here we have a ſhort hiſtory of theſe early attempts at dramatic muſic on our ſtage, in which, as in the moſt ſucceſsful repreſentations of this kind in later times, the chief part of the dialogue was ſpoken, and recitative, or muſical declamation, which ſeems to be the true criterion and characteriſtic of Italian operas, but ſeldom uſed, unleſs merely to introduce ſome particular airs and choruſes: as in the modern Comus, the air, "On ev'ry hill, in ev'ry dale," is preceded by the ſhort recitative "How gentle was my Damon's air."

Upon examining this muſic, it appears to have been very much compoſed on Lulli's model. The melody is neither recitative nor air, but partaking of both, with a change of meaſure as frequent as in any old French opera which we ever ſaw.

Lock had genius and abilities in harmony ſufficient to have ſurpaſſed his model, or to have caſt his movements in a mould of his own making; but ſuch was the paſſion of Charles II. and conſequently of his court at this time, for every thing French, that in all probability Lock was inſtructed to imitate Cambert and Lulli. His muſic for the witches in Macbeth, which, when produced in 1674, was as ſmooth and airy as any of the time, has now obtained, by age, that wild and ſavage caſt which is admirably ſuited to the infernal characters that are ſuppoſed to perform it.

In the third introductory muſic to the Tempeſt, which is called a *curtain tune*, probably from the curtain being firſt drawn up during the performance of this ſpecies of overture, he has, for the firſt time that is come to our knowledge, introduced the uſe of *creſcendo* (louder by degrees,) with *diminuendo*, and *lentando*, under the words *ſoft* and *ſlow by degrees*. No other inſtruments are mentioned in the ſcore of his opera of Pſyche, than *violins* for the ritornels; and yet, ſo ſlow was the progreſs of that inſtrument during the laſt century, that in a general catalogue of muſic in 1701, ſcarce any compoſitions appear to have been printed for its uſe.

This muſician was of ſo iraſcible a diſpoſition, that he ſeems never to have been without a quarrel or two on his hands. For his furious attack on Salmon, for propoſing to reduce all the clefs in muſic to one, (ſee SALMON and CLEF,) he had a quarrel with the gentlemen of the Chapel Royal, early in Charles II.'s reign. Being compoſer in ordinary to the king, he produced for the Chapel Royal a morning ſervice, in which he ſet the prayer after each of the ten commandments, to different muſic from that to which the ſingers had been long accuſtomed, which was deemed an unpardonable innovation, and on the firſt day of April 1666, at the performance of it before the king, there was a diſturbance and an obſtruction for ſome time to the performance. To convince the public that it was not from the meanneſs or inaccuracy of the compoſition, that this impediment to its performance happened, Lock thought it neceſſary to print the whole ſervice; and it came abroad, in ſcore, on a ſingle ſheet, with a long and laboured vindication, by way of preface, under the following title; "Modern church-muſick pre-accuſed, cenſured and obſtructed in its performance before his majeſty."

Lock was long ſuſpected of being a Roman Catholic, and it is probable that this new ſervice, by leaning a little more towards the maſs, than the ſervice of the Proteſtant cathedral, may have given offence to ſome zealous members of the church of England.

The public were indebted to Lock for the firſt rules that were ever publiſhed in England, for a *baſſo continuo*, or *thorough-baſe*; theſe rules he gave to the world, in a book entitled "Melotheſia," London, oblong 4to. 1673. It is dedicated to Roger l'Eſtrange, eſq. afterwards ſir Roger l'Eſtrange, an ingenious man, a good muſician, and an encourager of its profeſſors. It contains, beſides the thorough-baſe rules, ſome leſſons for the harpſichord and organ by Lock himſelf, and others. He was author likewiſe of ſeveral ſongs printed in "The Treaſury of Muſic," "The Theatre of Muſic," and other collections of ſongs. In the latter of theſe is a dialogue, "When death ſhall part us from theſe kids," which, with Dr. Blow's "Go, perjured man," was ranked among the beſt vocal compoſitions of the time.

It is preſumed, that when he was appointed compoſer in ordinary to the king, he was profeſſionally a member of the church of England; but it is certain that he went over to the Romiſh communion afterwards, and became organiſt to queen Catherine of Portugal, the conſort of Charles II. and died a Papiſt in 1677.

LOCK, a well-known inſtrument for ſecuring doors and preventing them from being opened, except by means of the key adapted to it. A common lock conſiſts of a ſtrong bolt, which muſt be fitted in a proper box or caſe affixed to the door, and incloſing it on all ſides, to defend it from violence, that it cannot be withdrawn, except by the application of the key, which ſhould enter the lock by a ſmall key-hole, and be ſurrounded by numerous wards, that occaſion the paſſage the key paſſes through, in turning round to move the bolt, to be very crooked and intricate, and thus preventing the introduction of any inſtrument or falſe key to withdraw the bolt. The third part of the lock is the tumbler, which is a catch or click holding the bolt from being withdrawn, except the tumbler is firſt removed by the key, which is done at the ſame time it ſhoots the bolt. This common lock cannot be made perfectly ſecure from being picked or opened without the right key, from the circumſtance that the wards, though they may be variouſly diſpoſed, ſo as to require a very crooked key, muſt be always left fixed in the lock, and their figure may be taken by introducing a ſmall falſe key, covered with wax or other plaſtic ſubſtance, and receiving the impreſſion of the wards, from which information a falſe or ſkeleton key may be made, that will enter the lock and withdraw the bolt; or, if it will only raiſe up the tumbler, the bolt may ſometimes be forced back by other means. Another reaſon of the inſufficiency of the common lock is, that the variations capable of being made in the arrangement of the wards are not ſufficient to produce the required number of locks without having great numbers exactly alike, and their keys capable of opening each other reciprocally; from which circumſtance they become but an imperfect ſecurity, as any ill-diſpoſed perſon may, by furniſhing himſelf with a great variety of old keys, be enabled to open almoſt any common lock; particularly if theſe keys are filed away to ſkeletons, that is, leaving as little as poſſible of the ſolid part of the key, which will then have a greater chance of paſſing in between the intricate wards.

To produce a lock which would be free from theſe objections has been the ſtudy of many ingenious mechanics, whoſe various locks have different properties and advantages. We have devoted *Plate* XXI. *Miſcellany*, to the explanation of two capital locks, one by Mr. Thomas Rowntree, which is an improvement upon the common tumbler-lock, and another by Mr. Joſeph Bramah, which is on an entirely different principle.

Mr. Rowntree's lock is repreſented in *figs.* 5, 6, 7, and 8; in theſe the following parts are thoſe of the common lock: A A is the plate which incloſes the whole mechaniſm, and faſtens it to the door; B B, *fig.* 6, is the bolt, which is guided in its motion by ſliding under two bridges C, D, ſcrewed to the main plate; E, E, are four pillars which ſupport a plate to cover the works: this plate has the key-hole in it; F, &c. are the circular wards ſurrounding the centre pin; and *a*, *fig.* 6, is the key which, in turning round, acts in a notch *r* in the bolt, and ſhoots it forwards or backwards; G is the tumbler: it is a plate ſituated beneath the bolt and moving on a centre pin at *d*. See alſo *fig.* 8, which is a ſeparate view of the tumbler; it has a catch *e* projecting upwards from it, which enters the notches *f* or *g*, *fig.* 6, in the bolt, and thus firmly retains the bolt; the former when it is locked, and the latter when it is drawn back. H is a ſpring which preſſes the tumbler forwards; the key *a*, in turning round, acts firſt againſt the part *c c* of the tumbler, and raiſes it ſo as to remove the catch *e* from the notches *f* or *g*, and then the key enters the notch *r* in the bolt, and moves it. In this, which is the common lock, it will be ſeen there is no ſecurity, except what ariſes from the intricacy of the wards F ſurrounding the key; for a falſe key, or any other inſtrument which is of the ſame length as *a*, will, if it can paſs the wards, raiſe the tumbler and draw back the bolt. Mr. Rowntree has, by applying an ingenious contrivance to this lock, rendered it ſo ſecure, that it will be nearly impoſſible to pick or open it with any other than the true key. To the tumbler he has added a piece of metal *h*, *figs.* 7 and 8, called its *fin*, fixed to its lower ſide. When the tumbler is locked in the notches *f*, *g*, of the bolt, the fin applies itſelf to a cluſter of ſmall wheels I, *figs.* 5 and 8, all fitted on one centre pin beneath the tumbler: the edges of theſe wheels ſtop the fin *h*, and prevent the tumbler being raiſed; but each wheel has a notch *i*, *fig.* 8, cut in its circumference, and when they are all placed, ſo that every notch is turned to the ſide oppoſite the fin of the tumbler, and forming one notch through the whole cluſter of wheels, then the fin is at liberty to enter this notch, allowing the tumbler to riſe: but when the tumbler is down, and the plain edges of all or any of the wheels are preſented to the fin, the tumbler cannot be raiſed unleſs the wheels are firſt put into the right poſition above-mentioned: this is done by a number of levers K, *figs.* 5 and 7, all centred on one pin at *k*. At the oppoſite end each has a tooth *m*, entering a notch in the wheel belonging to it, ſo that when any lever is preſſed outwards it turns its wheel round. The levers are preſſed towards the key by a ſpring *n* applied to each, and in this ſtate they reſt againſt a pin *o* fixed in the plate. The wheels are now diſarranged completely, every one preſenting its plain edge to the fin, but every one requiring a different degree of motion to bring the notch round to the proper poſition. When the key is introduced and turned round, it firſt operates upon the curved part *p q*, *fig.* 5, of the levers K, and raiſing them, turns all the circles I at once into the proper poſition. The key, in turning farther round, operates on the part *c c*, *fig.* 6, of the tumbler, now at liberty to move, and by raiſing it releaſes the bolt, and in turning ſtill further round, it ſeizes the notch *r* of the bolt, as in *fig.* 6, and ſhoots it. The key is cut into ſteps of different lengths, as ſhewn at *v v*, in *fig.* R: each ſtep operates on its reſpective lever K in a different degree, and turns its circle I the proper quantity. The notch at *s* acts upon the tumbler, and the plain part *t* moves the bolt. In this lock there is no poſſibility of picking it, for if all the levers except one were raiſed the proper quantity, that one would detain the tumbler as effectually as the whole number; and a falſe key, beſides having the wards as R, muſt have all the notches *v*, *v*, of the exact depth, neither greater nor leſs, or it will not open the lock, even if one alone is incorrect. If the key is loſt, when a new one is made, the maker takes out the levers K and circles I, and arranging them in a new order, one upon the other, making the new key to fit the new arrangement, and then the old key will not open the lock; though none of the parts are altered, but only their arrangement. The ſame may be done if it be ſuſpected that an impreſſion has been fraudently taken from the key to make a falſe one by.

The locks invented by Mr. Joſeph Bramah diſplay great ingenuity, and demand a particular deſcription, having been in very general uſe for many years paſt, and greatly admired. He obtained a patent for his invention in 1784, and eſtabliſhed a manufactory of them, in which he employed a number of ingenious tools and engines for the fabrication of the different parts. One of Mr. Bramah's ſimpleſt forms of a lock for a drawer, or for a door, is repreſented in *figs.* 1, 2, 3, 4, *Plate* XXII. *Miſcellany*, in which A repreſents the bolt, fitted to ſlide on the metal plate B B C, by paſſing through a hole in the ſide C, which is turned up, as ſhewn in *fig.* 3: the other end of the bolt is guided by paſſing under proper grooves in the lower ſide of the circular box D D, which is ſcrewed to the plate B to confine the bolt down. It contains the whole mechaniſm of the lock, conſiſting of an interior cylinder or barrel E E, ſhewn in the ſection *fig.* 3, with its appendages in perſpective in *fig.* 4. This barrel is fitted to turn round within the box D D, the upper end *a a* being received into a cavity exactly fitting it, and the middle encompaſſed by a circular ring of ſteel plate *b b*, ſcrewed into the box as ſhewn in *fig.* 3, and one-half ſhewn at *b*, *fig.* 4. The ring enters a circular groove formed round the barrel, and thus confines it from having any other motion than a rotation on its axis, and this only by the aid of the key R, as will be explained. The barrel has a hole through its centre, which is cloſed at bottom by a circular plate F, ſcrewed to it, and ſupporting the central pin G, which occupies the centre of the hole through the barrel: this centre pin guides the key in entering the lock. When the barrel E E is turned round by the key, it ſhoots the bolt A, by an ingenious contrivance, explained in *fig* 2, an aperture being cut through the plate B B C to exhibit it. The plate F, on the lower end of the barrel E, has a pin *f* projecting from it: this pin enters a curved opening, at a ſmall diſtance from the centre, and therefore deſcribes a circle when the barrel is turned round, cut through the bolt A, as is ſhewn by the dark curve F in *fig.* 2. In the poſition there ſhewn the bolt is withdrawn, and the pin *f*, reſting againſt the ſolid part of the groove, prevents the barrel being turned round any farther in the direction from F to *f*: but by the application of the key, the barrel may be turned in the other direction from *f* to F, in which courſe it paſſes round in a circular part of the groove, and therefore produces no motion of the bolt A, until the pin *f* ſtrikes the ſtraight part *g* of the groove, and acts againſt it to throw the bolt forwards: and when the barrel has made a complete circuit, and the pin *f* is again come to the ſame poſition it was at firſt, the bolt is ſhot out as at *fig.* 1, and the pin is reſting in the hollow *h*, which prevents it moving any farther in the ſame direction. When the barrel is turned back again, the pin *f* acts againſt the notch *i* and the curved part *k* of the groove, and withdraws the bolt into the poſition of *fig.* 2: now the pin *f*, either when the bolt is ſhot out or in, is in a right line with the centre of the barrel E, to which it is fixed, and the direction of the bolt's motion. By this means, no force whatever applied to drive back the bolt can have the leaſt tendency to turn the barrel round, and ſtrain the mechaniſm which prevents its motion, unleſs the parts are firſt put into a particular arrangement, by the application of the key. The interior mechaniſm muſt be explained by *fig.* 4, in which *l*, *m*, *n*, repreſent ſmall ſteel ſliders, which are fitted into proper grooves or ſlits, made in the ſubſtance of the barrel E. Of theſe there are ſix in number, arranged round the barrel, and projecting a little from its exterior ſurface in the ſmall part. Theſe ſliders are received in notches *y*, *z*, in the fixed ſteel ring *b b*, before deſcribed; and thus effectually detain the barrel at ſix points from being turned round, except it is firſt unlocked by the key R being introduced at the key-hole H, and the ſliders preſſed down by it, ſo as to bring the notches (of which each ſlider has one, as at *r* *fig.* 4.) all oppoſite the ſteel plate *b b*, and then the barrel may be turned round. When the key is abſent, the ſliders are raiſed up by a braſs ring *v* ſliding on the central pin G, and lifted up by a ſpiral ſpring *w*. The key has ſix notches cut in the end of it, as ſhewn at S, which is an end view: each notch in the key includes one of the ſix ſliders *l*, *m*, *n*, and

and the key, being forced down into the key-hole H, depreſſes all the ſliders at once, until the projecting leaf *t* of the key ſtops upon the bottom of the receſs *x*, cut in the upper edge of the barrel. In this poſition the ſliders are depreſſed, ſo that the notch *r* made in each ſlider comes exactly oppoſite the ſteel ring *b b*, and the barrel is at liberty to turn round all the ſliders, being by this means removed, or at leaſt relieved, from the ſteel ring, which, as before-mentioned, embraces a groove cut round the barrel, but which cannot turn round therein unleſs the ſliders are alſo moved by the key, that the notches cut in them coincide with the groove cut round the barrel, and then it can turn freely round. The key, having thus relieved the barrel by being thruſt in as far as it can go, obtains a hold of the barrel to turn it round, by the leaf *t* entering the receſs *x*, which it exactly fills up, ſo as to form a continuation of the circular top of the barrel: but as ſoon as the key is turned round with the barrel a ſmall quantity, its leaf is caught beneath the circular cavity in the top of the box D, and thus the key is prevented from being thrown out by the ſpiral ſpring *w*, until it has been turned quite round, and locked or unlocked the bolt: then the leaf of the key coming oppoſite the enlargement *z*, *fig.* 1, of the key-hole H, the ſpring throws the key out and raiſes all the ſliders, that they may interlock with the ſteel plate *b b*, and prevent the barrel from turning, unleſs the key is again put in, (its leaf being oppoſite the aperture *z* of the key-hole,) and being thruſt forwards as far as it will go, the barrel will turn round very eaſily; and when it has made a complete circuit, the lock is opened, and the key thrown out of the key-hole by the ſpring.

The ſecurity of this ingenious lock from being picked, or opened by a falſe key, depends upon a circumſtance not yet mentioned, which is, that the notches in the ſix ſliders are ſo made, that every one requires to be depreſſed a different quantity to bring them all at once oppoſite the ſteel ring, in which poſition alone the barrel can be moved. For this reaſon the ſix notches in the key are all of different depths, correſpondent to the poſitions of the notches in their reſpective ſliders; and unleſs each notch in the key is of the proper depth, the lock cannot be opened, for any one being too deep, that ſlider will not be preſſed low enough to relieve the barrel, and will hold it faſt, though all the others may be correct: on the other hand, any notch not being of ſufficient depth, the ſlider it acts upon will be preſſed too far, and in this caſe the notch in it, having paſſed by the ſteel ring, will lock the barrel as effectually as though it was not far enough. Thus this lock admits of an immenſe number of combinations; 1ſt, in the number of the ſliders; 2dly, the depths of the different notches in the key; and 3dly, the arrangement of theſe ſliders. The combination of theſe three changes admits ſuch an immenſe number of varieties of locks, that it never need happen that two locks ſhould be made to open by the ſame key. Any of Mr. Bramah's locks may be arranged ſo as to require a new and different key in caſe the original ſhould be loſt or ſtolen: for this purpoſe the lock muſt be opened, and the ſliders taken out and changed into different grooves: a new key muſt now be made, with the grooves of the ſame depth of the original key, but arranged in a different order, correſponding with the new arrangement of the ſliders. The old key will not now open the lock.

To pick a lock of this kind is perhaps impoſſible; becauſe, though the ſliders are expoſed to the examination of any perſon, yet no information can be obtained of the depth of each of the ſliders required to be depreſſed; for, unleſs they are all together preſſed down, the barrel cannot be turned in the leaſt, and without turning it, no gueſs can be made by preſſing down any one ſlider of the depth at which the notch in it will be oppoſite the ſteel ring. Another great advantage of theſe locks is, that from the circumſtance before explained, of the bolt having no action to turn the barrel, though the barrel has a great power to ſhoot the bolt, a ſtrong lock may have but a very ſmall key. For inſtance, the bolt of the lock, in the plate which is drawn its full ſize, is of great ſtrength, while the key R is ſo ſmall, that it may always be carried ſuſpended to the watch chain, and then it will not be in danger of being loſt or miſlaid, as one may happen to loſe a key, and give opportunity for ill diſpoſed perſons to make a falſe key from it, unknown to the owner.

A lock invented by Mr. Stanſbury, an American gentleman, has great merit. To explain it, we muſt ſuppoſe that a flat circular plate is fitted to turn round upon the centre pin for the key, and that this plate, when turned round, ſhoots the bolt, which may be done by various means. The locking part conſiſts of four, ſix, or more ſmall ſteel pins, which are received in holes made very near each other, through both the circular turning plate, and the fixed plate beneath it. By theſe pins the circular plate is held faſt from turning. The key has the ſame number of pins, and arranged in the ſame poſition and diſtance as the pins in the plate. The key being introduced, it is preſſed forwards againſt the circular plate, and turned round till the pins in it come over the pins in the circular plate, and the preſſure of the hand forces the pins out of the circular plate, the pins in the key occupying the place of them. The plate is now relieved, and the key has hold of the plate to turn it round and open the lock. Each pin is provided with a ſpring behind the fixed plate to force it forwards. The difficulty of making a falſe key to this lock is very great; as any error in the number, ſize, poſition, or length of the pins, will prevent it from opening the lock. To avoid the danger of impreſſions being taken, many marks are ſtamped upon the circular plate, which are exactly the ſame at the marks of the real pins: thus an impreſſion taken from it would only miſlead.

Mr. Stanſbury has alſo made an ingenious improvement upon the common ſpring door-lock. The handle which opens the ſpring catch for faſtening the door, inſtead of requiring to be turned round, is made ſo that it withdraws the ſpring catch, by puſhing the handle on one ſide of the door and pulling it on the other. This method is extremely convenient; for preſſing the handle releaſes the lock, and continuing the preſſure opens the door, and pulling the handle on the other ſide has the ſame effect. A perſon with his hands full may open ſuch a door by only leaning againſt the handle.

Lock, or *Weir*, in *Inland Navigation*, the general name for all thoſe works of wood and ſtone, made to confine and raiſe the water of a river: the banks alſo which are made to divert the courſe of the river, are called by theſe names in ſome places. But the term *lock*, or *pound-lock*, is more particularly appropriated to expreſs a contrivance, conſiſting of two gates, or pairs of gates, called the lock-gates, and a chamber between, in which the water may be made to coincide with the upper or lower canal, according as the upper or lower gates communicating with it are opened; by which means boats are raiſed or depreſſed from one level or reach of a canal to another. See *Plate* V. *Canals*.

Lock *of Water*, is the meaſure equal to the content of the chamber of the locks, by which the conſumption of water on a canal is eſtimated.

Lock-*keeper*, a perſon who attends the locks to take care of them, and to aſſiſt the boatmen in paſſing through them.

Lock-*paddles* are the ſmall ſluices that ſerve to fill and empty the locks.

Lock-*ſils* are the angular pieces of timber, (*h, h, Plate* V. *Canals, fig.* 36.) at the bottom of the lock, againſt which the gates ſhut.

Lock-*weirs*, or *Paddle-weirs*, are the over-falls behind the upper gates, (*z, z, Plate* V. *fig.* 35.) by which the waſte-water of the upper pound is let down through the paddle-holes into the chamber of the lock.

To Lock, in *Fencing*, is to ſeize your adverſary's ſword-arm, by twining your left arm round it, after you cloſe your parade, ſhell to ſhell, in order to diſarm him.

LOCKARTSBURG, in *Geography*, a town of America, in Luzerne county, Pennſylvania, ſituated on an iſthmus, formed by the confluence of the Suſquehanna and Tioga rivers, about a mile above their junction.

LOCKE, John, in *Biography*, one of the greateſt philoſophers and moſt powerful writers that ever adorned this country, was born at Wrington, in Somerſetſhire, on the 29th of Auguſt 1632. His father was a gentleman of ſtrict probity and economy, and he poſſeſſed a handſome fortune. He took great pains in the education of his ſon; and, when he was of a proper age, ſent him to Weſtminſter ſchool, where he continued till the year 1651, when he was entered a ſtudent of Chriſt-church college, in the univerſity of Oxford. Here he was diſtinguiſhed above all his contemporaries, and was conſidered to be the moſt ingenious young man in the college. It appears, however, that he was diſguſted with the method of ſtudy preſcribed to him, which was after the manner of the Peripatetics; and it is ſaid, that the books which firſt gave him a reliſh for the ſtudy of philoſophy were thoſe written by Des Cartes. Having taken his degrees in arts in 1655 and 1658, Mr. Locke for ſome time cloſely applied himſelf to the ſtudy of phyſic; and it is certain that, for a ſhort time, he followed it as a profeſſion. In the year 1664 he accepted an offer to go abroad, as ſecretary to ſir William Swan, envoy from Charles II. to the elector of Brandenburgh; but returning to England again within leſs than a year, he reſumed his ſtudies at Oxford with renewed vigour, applying himſelf particularly to natural philoſophy. In 1666 he was accidentally introduced to the acquaintance of lord Aſhley, afterwards earl of Shafteſbury, in the capacity of a medical practitioner, during the abſence of the phyſician who regularly attended his lordſhip. When the noble lord left Oxford to go to Sunning Hill, he made Mr. Locke promiſe him a viſit there, which promiſe he performed in 1667. Having ſecured him as an inmate, lord Aſhley ſuffered himſelf to be governed entirely by his advice, and became ſo much attached to him, that he would not ſuffer him to practiſe medicine out of his own family, except in the caſe of ſome particular friends; and perceiving that the great abilities of Mr. Locke were calculated to render him eminently ſerviceable to the world in other departments of knowledge, urged him to apply his ſtudies to ſtate affairs and political ſubjects. To theſe Mr. Locke was naturally inclined, and ſucceeded ſo well, that lord Aſhley began to conſult him on all occaſions. He was now introduced to the ſociety of ſome of the moſt eminent men of the age, who were all delighted with his converſation. In the year 1668, Mr. Locke accompanied the earl and counteſs of Northumberland in a tour to France, and remained in that country with the lady, while his lordſhip ſet off to Italy, with an intention of viſiting Rome. This nobleman, however, died on his journey, and Mr. Locke accompanied the counteſs to England, and again took up his reſidence at lord Aſhley's. His lordſhip, at that period chancellor of the exchequer, having, in conjunction with other noble lords, obtained a grant of Carolina in North America, employed Mr. Locke to draw up a conſtitution for that province. In executing this taſk, he had formed articles relative to religion and public worſhip on thoſe enlarged principles of toleration, which were agreeable to his own enlightened views upon that ſubject. The clergy, however, jealous of a diminution of their powers, cauſed an additional clauſe to be inſerted, ſecuring the countenance and ſupport of the ſtate only to the exerciſe of religion according to the diſcipline of the eſtabliſhed church. Mr. Locke, notwithſtanding his connection with lord Aſhley, made frequent viſits to Oxford, though he was at the ſame time engaged to inſpect the education of his lordſhip's eldeſt ſon, an office which he executed with the greateſt care, and to the entire ſatisfaction of his employer. To Mr. Locke, likewiſe, was confided the important charge of ſelecting a wife for the young man. This was a taſk of great difficulty, as the father determined he ſhould only marry a lady of good family, of an agreeable temper, a fine perſon, and, above all, of good education and excellent underſtanding. Notwithſtanding the difficulties attending ſuch a commiſſion, Mr. Locke undertook it, and executed it to the perfect ſatisfaction of all parties. The eldeſt ſon by this marriage, afterwards the author of the "Characteriſtics," was committed to the care of Mr. Locke in his education, and gave evidence to the world of the maſter-hand which had directed and guided his genius. In 1670 Mr. Locke began to form the plan of his "Eſſay on Human Underſtanding;" but he was too much engaged by his patron to make much progreſs in the work. In 1672, lord Aſhley was created earl of Shafteſbury, and appointed to the high dignity of lord high chancellor of England. His lordſhip immediately made him his ſecretary of the preſentations; but he held that place only till the end of the following year, when the earl was obliged to reſign the great ſeal. After this, lord Shafteſbury was preſident of the board of trade, and Mr. Locke was appointed ſecretary to the ſame. The commiſſion being diſſolved in 1674, he was again at leiſure, was admitted to the degree of bachelor of phyſic, and began to turn his attention to that faculty, as the means of future ſupport. He was at this time in the higheſt eſtimation with ſeveral perſons of eminence in the medical profeſſion: Dr. Sydenham, among others, ſpeaking of him, ſays, "If we conſider his genius, and penetrating and exact judgment, or the ſtrictneſs of his morals, he has ſcarcely any ſuperior, and few equals now living." In 1675, Mr. Locke ſought relief from a pulmonary complaint by travelling to the ſouth of France, where he became acquainted with the earl of Pembroke, to whom he communicated his plan of writing the "Eſſay on Human Underſtanding." He afterwards ſettled at Paris, where he obtained the friendſhip of ſeveral men of letters. In 1679 the earl of Shafteſbury, being reſtored to favour at court, and made preſident of the council, ſent to requeſt that Mr. Locke would return home without delay. He inſtantly complied; but within ſix months that nobleman was again diſplaced, for refuſing his concurrence with the deſigns of the court, which aimed at the eſtabliſhment of popery and arbitrary power; and in 1682, he found it neceſſary to retire to the continent, to avoid a proſecution for high treaſon, on account of offences charged upon him, probably without the colour of reaſon or truth. Mr. Locke, whoſe character was above all ſuſpicion, remained ſteadily attached to his patron, following him into Holland; and upon his lordſhip's death, which happened ſoon afterwards, he did not think it ſafe to return to his native country, where his intimate connection with lord Shafteſbury had created him ſome powerful and malignant enemies. Their malice purſued him to the utmoſt extent of their means; and the dean of Chriſt-church had orders from the king to eject Mr. Locke from his ſtudent's place, which was accordingly done. On the acceſſion of James II., William Penn, the quaker, who was the friend of Locke in his adverſity, uſed his intereſt with the king to procure a pardon for him; and would have obtained it, had not Mr. Locke declined the acceptance of ſuch an offer, declaring that he had no occaſion for a pardon, having never been guilty of any crime. In 1685, when the duke of Monmouth and his party were making preparations in Holland for his raſh and unfortunate enterprize, the Engliſh envoy at the Hague demanded that Mr. Locke, among others, ſhould be given up, on ſuſpicion of his being actively engaged in the undertaking. This ſuſpicion, though entirely groundleſs, obliged him to lie concealed nearly a year; till it was rendered perfectly evident, even to his enemies and their ſpies, that he had no concern whatever in the buſineſs. Towards the end of the year 1686 he appeared again in public, and ſoon afterwards was the principal agent in forming a literary ſociety at Amſterdam, of which Limborch, Le Clerc, and other learned men were members, who met together weekly for converſation upon ſubjects of univerſal learning. In the following year he finiſhed his great work, the "Eſſay concerning Human Underſtanding," which had been the principal object of his attention ſeveral years, and which proves how well he ſpent the period of his exile from England. That the public might be apprized of the outlines of his plan, he himſelf made an abridgment of it, which his friend Le Clerc tranſlated into French, and inſerted in one of his "Bibliotheques." This abridgment was ſo highly approved by the literati of that period, and by thoſe who were ſincerely attached to truth and juſt principles, that they took every opportunity of expreſſing the ſtrongeſt deſire to ſee the complete work in its original ſtate. During his concealment, he wrote his "Letter concerning Toleration," which was firſt publiſhed in the Latin language at Gouda, in 1689, and entitled "Epiſtola de Tolerantia ad clariſſimum Virum T. A. R. P. T. O. L. A. Scripta à P. A. P. O. J. L. A." The former of theſe ſets of letters were intended to ſignify Theologiæ apud Remonſtrantes Profeſſorem, Tyrannidis Oſorem Limburgium Amſtelodamenſem; and the latter, Pacis Amico, Perſecutionis Oſore, Johanne Locke, Anglo. This letter he afterwards tranſlated into Engliſh, and publiſhed in London in the year 1690. It was ſpeedily tranſlated into the Dutch and French languages, and has been exceedingly popular with liberal people of all countries from that period to the preſent. It has been frequently reprinted in forms adapted for general circulation, and has been diſtributed by perſons of fortune and rank, among whom may be mentioned, in our own country, his grace the late duke of Grafton. This epiſtle, though ſo highly approved, was ſeverely attacked by a clergyman of Oxford, who wrote three pamphlets againſt it; two of which Mr. Locke anſwered, defending and juſtifying his principles with invincible ſtrength of argument: and though he was in a declining ſtate of health, when his antagoniſt, after twelve years' ſilence, publiſhed his third pamphlet againſt it, yet he began a reply to him in a "Fourth Letter concerning Toleration." Though this was not finiſhed, yet the fragment has been publiſhed in Deſmaizeaux's edition of his works.

To return, however, to the narrative of Mr. Locke's life, in the order of time. The revolution of 1688 opened a way for his return into his own country, whither he came in the ſame fleet which conveyed the princeſs of Orange; and upon the reſtoration of public liberty, he did not heſitate to aſſert his own private rights, and accordingly put in his claim to the ſtudent's place in the college of Chriſt's-church, of which he had been unjuſtly deprived. For the ſake of peace, he was adviſed to deſiſt from his claim. As he was conſidered to be a ſufferer for the principles of the revolution, he might have obtained ſome very conſiderable poſt under government: but he contented himſelf with that of "Commiſſioner of Appeals," worth about 200*l. per annum.* In the year 1689, Mr. Locke had an offer to go abroad in a public character; but he declined the honour and advantages attached to ſuch a ſituation, on account of the infirm ſtate of his health: and in the following year he publiſhed his "Eſſay," which has given him an immortal reputation; and which, at the time, though it had many enemies, was ſtyled "one of the nobleſt, moſt uſeful, and moſt original books the world ever ſaw." Thoſe who diſliked every thing like innovation, oppoſed the progreſs of our philoſopher's principles as laid down in his "Eſſay." It was even propoſed, at a meeting of the heads of the houſes of the univerſity of Oxford, to cenſure and diſcourage the reading of it; and after long and warm debates among themſelves, it was agreed that each individual, at the head of a college, ſhould endeavour to prevent it from being read by the ſtudents: a ſure method of rendering every ſpirited young man anxious to peruſe it, and even imbibe its principles. The old and the prejudiced were afraid of the light which was diffuſing itſelf in the world, but they could not reſtrain its effects: the attacks of Mr. Locke's various opponents did but increaſe his reputation, and render his principles more generally ſtudied and adopted. Mr. Locke's next publication was his "Two Treatiſes on Government;" in which he vindicated the principles upon which "the Revolution" was founded, and completely demoliſhed ſir Robert Filmer's falſe principles; pointing out, at the ſame time, the true origin, extent, and end of civil government. About this period, the public coin of the kingdom was known to be in a very bad and depreciated ſtate, having, by being clipped and ſweated, loſt one-third of its weight. The magnitude of this evil, and the miſchiefs which it threatened, called for the attention of parliament; and Mr. Locke, with the view of aſſiſting thoſe who were at the head of affairs to form a right underſtanding of this matter, and to excite them to rectify ſuch abuſes, printed a tract, entitled "Some Conſiderations of the Conſequences of lowering the Intereſt, and raiſing the Value of Money." He had warned the public of their danger, and ſaid, "the nation was in greater danger from a ſecret unobſerved abuſe, than from all thoſe other evils of which perſons were generally ſo apprehenſive; and that if care was not taken to rectify the coin, that irregularity alone would prove fatal to us, though we ſhould ſucceed in every thing elſe." Mr. Locke publiſhed other tracts on the ſame ſubject, by which he convinced the world that he was as able to reaſon on trade and buſineſs as on the moſt abſtract queſtions of ſcience. He was accordingly conſulted by the miniſtry relative to a new coinage of ſilver. With the earl of Pembroke, then lord keeper of the privy ſeal, he was accuſtomed to hold weekly conferences; and he was in habits of intimacy and friendſhip with the earl of Peterborough, at whoſe houſe, at Fulham, he always met with a hoſpitable and kind reception, when the delicacy of his health obliged him to quit the metropolis. He was afterwards obliged to leave London entirely, and accepted of the generous offer of ſir Francis Maſham, at Oates in Eſſex, to become a reſident in his houſe, where he ſpent the remainder of his life. Here he was

was received on his own terms, that he might have his entire liberty, and look upon himſelf as at his own home; and here he chiefly purſued his future ſtudies, being ſeldom abſent, becauſe the air of London grew more and more troubleſome to him. In 1693 he publiſhed his “Thoughts on Education,” which he improved in ſome ſubſequent editions; and in 1695 he was appointed, by the king, one of the “Commiſſioners of Trade and Plantations,” which obliged him to be more frequently in London than he had been for ſome time paſt. In the ſame year he publiſhed his excellent treatiſe, entitled “The Reaſonableneſs of Chriſtianity as delivered in the Scriptures;” of which he afterwards publiſhed a vindication, in anſwer to a ſcurrilous attack by Dr. Edwards, entitled “Socinianiſm unmaſked.” Scarcely was Mr. Locke diſengaged from this controverſy, before he was drawn into another, occaſioned by the publication of Mr. Toland's “Chriſtianity not myſterious,” in which he endeavoured to prove “that there is nothing in the Chriſtian religion not only contrary to reaſon, but even nothing above it;” and in explaining his notions, he made uſe of ſeveral arguments from Mr. Locke's “Eſſay.” About the ſame time, ſeveral treatiſes were publiſhed by ſome Unitarian writers, maintaining that there was nothing in the Chriſtian religion but what was rational and intelligible, which ſentiment had been advanced by Mr. Locke. The uſe which was made of his writings in theſe inſtances, determined Dr. Stillingfleet, biſhop of Worceſter, to make an attack upon the author, in his “Defence of the Doctrine of the Trinity,” publiſhed in 1697. Mr. Locke wrote an anſwer, and the controverſy was carried on till the death of the biſhop: The candid of every party admitted that Mr. Locke was too powerful for the learned prelate, and M. Le Clerc, ſpeaking of the diſcuſſion, ſays, “Every body admired the ſtrength of Mr. Locke's reaſonings, and his great clearneſs and exactneſs, not only in explaining his own notions, but in confuting thoſe of his adverſary. Nor were men of underſtanding leſs ſurpriſed, that ſo learned a man as the biſhop ſhould engage in a controverſy, in which he had all the diſadvantages poſſible: for he was by no means able to maintain his opinions againſt Mr. Locke, whoſe reaſonings he neither underſtood, nor the ſubject itſelf about which he diſputed.” And an Iriſh prelate writing to Mr. Molyneux, the intimate friend of Mr. Locke, thus expreſſes himſelf on the ſubject: “I am wholly of your opinion, that he has laid the great biſhop on his back; but it is with ſo much gentleneſs, as if he were afraid not only of hurting him, but even of ſpoiling or tumbling his clothes. Indeed, I cannot tell which I moſt admire; the great civility and good manners in his book, or the forcibleneſs and clearneſs of his reaſoning.” Never, perhaps, was a controverſy managed with ſo much ſkill and art on one ſide, nor on the other, ſo unjuſtly, confuſedly, or ſo little to the credit of the author. The tracts on this controverſy were the laſt which Mr. Locke committed to preſs: he grew infirm more from diſeaſe than great age, and he determined to reſign his office of “Commiſſioner of Trade, &c.;” but he acquainted no perſon of his intention till he had given up his commiſſion into the king's own hand. His majeſty preſſed him to continue in the poſt, though he ſhould be unable to perform its duties; but Mr. Locke could not be induced to make ſuch a compromiſe, and he inſiſted upon ſurrendering the emoluments of a place that he felt himſelf incapable of filling. From this time, which was the year 1700, he lived altogether at Oates in Eſſex, and applied himſelf, without interruption, entirely to the ſtudy of the holy ſcriptures; and in the employment he found ſo much pleaſure, that he regretted his not having devoted more of his time to it in the former part of his life; and he replied, in anſwer to a young gentleman, who aſked what was the ſhorteſt and ſureſt way for a perſon to attain a true knowledge of the Chriſtian religion? “Let him ſtudy the holy ſcripture, eſpecially the New Teſtament. It has God for its author; ſalvation for its end; and truth, without any mixture of error, for its matter.” In 1703 he ſuffered much from an aſthmatic diſorder, but the pangs of bodily complaint were alleviated by the kind attentions of lady Maſham, who was the daughter of the learned Cudworth: ſtill he foreſaw that his diſſolution was not far diſtant, and he could anticipate it without dread, and ſpeak of it with perfect calmneſs and compoſure. Though few men had need of ſo little preparation for the important change as Mr. Locke, yet he felt it right to receive the ſacrament at home, in company with ſome friends, being unable to go to church. When the ceremony was finiſhed, he told the miniſter, “that he was in perfect charity with all men, and in a ſincere communion with the church of Chriſt, by what name ſoever it might be diſtinguiſhed.” He lived ſome months after this, which he ſpent in acts of piety and devotion: when he was meditating on the wiſdom and goodneſs of the Creator, he could not forbear crying out, “Oh the depth of the riches of the goodneſs and knowledge of God:” what he felt himſelf on this ſubject he was anxious to infuſe into the hearts of others. On the day previouſly to his departure he ſaid, “he had lived long enough, and was thankful that he had enjoyed a happy life; but that, after all, he looked upon this life to be nothing but vanity,” or, as he expreſſes a ſimilar ſentiment, in a letter which he left behind him for his friend Mr. Anthony Collins, one that “affords no ſolid ſatisfaction but in the conſciouſneſs of doing well, and in the hopes of another life.” He had no reſt that night, and begged in the morning to be carried into his ſtudy, where, being placed in an eaſy chair, he had a refreſhing ſleep for a conſiderable time. He then requeſted his valuable friend, lady Maſham, to read aloud ſome of the pſalms, to which he appeared exceedingly attentive, till feeling, probably, the approach of the laſt meſſenger, he begged her to deſiſt, and in a few minutes expired, on the 28th of October 1704, in the 73d year of his age. He was interred in the church of Oates, where there is a monument erected to his memory, with a Latin inſcription, which he had prepared for the purpoſe.

Such was the end of as illuſtrious a philoſopher as ever adorned our country: celebrated not only by his wiſdom, but by his piety and virtue, by his love of truth, and diligence in the purſuit of it, and by a noble ardour in defence of the civil and religious rights of mankind. That Mr. Locke poſſeſſed a noble and lofty mind, ſuperior to prejudice, and capable, by its native energy, of exploring the truth, even in the regions of the intellectual world before unknown; that his judgment was accurate and profound; that his imagination was vigorous; and that he was well furniſhed with the ornaments of elegant learning, were there no other proofs, might be concluded from his great and immortal work, “The Eſſay concerning Human Underſtanding.” Though we cannot agree with the learned author of the “Diverſions of Purley,” “that Mr. Locke never did advance a ſingle ſtep beyond the origin of Ideas and the compoſition of Terms;” yet it muſt be admitted, that this was the main object of his eſſay, though not at firſt perceived by Mr. Locke himſelf, as he acknowledges: but he adds, “when I began to examine the extent and certainty of our knowledge, I found it had ſo near a connection with words, that unleſs their force and manner of ſignification were firſt well obſerved, there could be very little ſaid clearly and pertinently concerning knowledge, which being converſant about truth, had conſtantly to do with propoſitions. And though it terminated in things, yet it was for the moſt part ſo much by the intervention of words, that they ſeemed ſcarce ſeparable from our general knowledge." And again, "I am apt to imagine, that were the imperfections of language, as the inſtrument of knowledge, more thoroughly weighed, a great many of the controverſies that make ſuch a noiſe in the world, would of themſelves ceaſe, and the way to knowledge, and perhaps peace too, lie a great deal opener than it does." Hence the author, juſt referred to, aſſumes, "that the more Mr. Locke reflected and ſearched into the human underſtanding, the more he was convinced of the neceſſity of an attention to language, and of the inſeparable connection between words and knowledge. He ſays, moreover, that it was a lucky miſtake which Mr. Locke made when he called his book "An Eſſay on the Human Underſtanding." For ſome part of the ineſtimable benefit of that book has, merely on account of its title, reached to thouſands more than, I fear, it would have done, had he called it (what it is merely) A Grammatical Eſſay, or a treatiſe on words, or on language. The human mind, or the human underſtanding, appears to be a grand and noble theme, and all men, even the moſt inſufficient, conceive that to be a proper object for their contemplation, while enquiries into the nature of language are ſuppoſed to be beneath the concern of their exalted underſtanding." We ſhall now quote Dr. Enfield's opinion of this great work. "Diſcarding," ſays he, "all ſyſtematic theories, he has, from actual experience and obſervation, delineated the features, and deſcribed the operations of the human mind, with a degree of preciſion and minuteneſs not to be found in Plato, Ariſtotle, or Des Cartes. After clearing the way by ſetting aſide the whole doctrine of innate notions, and principles both ſpeculative and practical, the author traces all ideas to two ſources, ſenſation and reflection; treats at large of the nature of ideas, ſimple and complex; of the operation of the human underſtanding in forming, diſtinguiſhing, compounding, and aſſociating them; of the manner in which words are applied as repreſentations of ideas; of the difficulties and obſtructions in the ſearch after truth, which ariſe from the imperfection of theſe ſigns; and of the nature, reality, kinds, degrees, caſual hindrances, and neceſſary limits of human knowledge." Mr. Locke's "Two Treatiſes of Government," will render his memory dear to the enlightened friends of civil and religious freedom: his letters on toleration, and his commentaries on St. Paul's epiſtles, are likewiſe held in high eſtimation.

Mr. Locke's private character cannot be wholly overlooked: he poſſeſſed a great knowledge of the world, and was intimately converſant in the buſineſs of it. He was prudent without cunning, and he engaged men's eſteem by his probity. Averſe from all mean compliances, his wiſdom, his experience, and his gentle manners, gained him the reſpect of his inferiors, the eſteem of his equals, the friendſhip and confidence of thoſe of higher quality. He was remarkable for the eaſe and politeneſs of his behaviour; and thoſe who only knew him by his writings, and who had conceived him to be a reſerved man, were ſurpriſed, if they happened to be introduced to him, to find him extremely affable, good-humoured, and complaiſant. Dr. Iſaac Watts deſcribes him as having a ſoul wide as the ſea; calm as night, bright as day. And the ſame author has a fine ode in his lyric poems, written on occaſion of Mr. Locke's dangerous illneſs, ſome time after he had retired to ſtudy the ſcriptures, of which we ſhall quote the firſt ſtanza.

"And muſt the man of wondrous mind,
Now his rich thoughts are juſt refin'd,
Forſake our longing eyes?
Reaſon at length ſubmits to wear
The wings of faith; and lo! they rear
Her chariot high, and nobly bear
Her prophet to the ſkies."

Among the honours paid to the memory of Mr. Locke, that of queen Caroline, conſort of George II. ought not to be overlooked, for that princeſs, having erected a pavilion in Richmond park, devoted to, or in honour of, philoſophy, placed in it Mr. Locke's buſt, with thoſe of Bacon, Newton, and Clarke, as the four chief of the Engliſh philoſophers. He left behind him ſeveral MSS., from which his executors, ſir Peter King and Anthony Collins, eſq. publiſhed, in 1705, his paraphraſe and notes upon St. Paul's epiſtle to the Galatians, which were ſoon followed by thoſe upon the Corinthians, Romans, and Epheſians, with an eſſay prefixed, "For the underſtanding of St. Paul's epiſtles, by conſulting St. Paul himſelf." In the following year the poſthumous works of Mr. Locke were publiſhed, compriſing a treatiſe "On the Conduct of the Underſtanding," intended as a ſupplement to the "Eſſay:" "An Examination of Malebranche's Opinion of ſeeing all Things in God." In 1708, ſome familiar letters between Mr. Locke and ſeveral of his friends were publiſhed. All the works of this great man have been collected, and frequently reprinted in different ſizes; in three vols. folio, in four volumes quarto, and lately in ten volumes 8vo. Biog. Brit. Life prefixed to Mr. Locke's works. Enfield's Hiſt. of Phil.

Locke, in *Geography*, a town of Pruſſia, in Ermeland; 11 miles from Heilſberg.

Locke, a military town of America, in Milton townſhip, New York, in Onondago county; 13 miles N.E. of the S. end of Cayuga lake.

LOCKENITZ, a town and caſtle of Brandenburg, in the Ucker Mark; 16 miles N.E. of Prentzlow.

LOCKER, in a *Ship*, a kind of box or cheſt made along the ſide of a ſhip, to put or ſtow any thing in.

Locker, *Gowlans*. See Hellebore, and Trollius.

Locker, *Shot*, in *Sea Language*. See Garland.

LOCKERBIE, in *Geography*, a market town ſituated in the pariſh of Dryſdale, Dumfriesſhire, Scotland. It is pleaſantly ſeated on the river Annan, at the diſtance of 12 miles from the county town. It conſiſts chiefly of one regular ſtreet, half a mile in length from north to ſouth, and this is interſected, at right angles, by another ſtreet of inferior extent. According to the parliamentary returns of 1801, the whole pariſh contained 322 houſes and 1607 inhabitants. The buildings in the town are chiefly of recent date. The pariſh church ſtands on an eminence at the head of the principal ſtreet. Two lakes formerly almoſt encircled the town. It has two fairs and ten markets during the year, at which upwards of 20,000 lambs are annually ſold; the greater part of which are principally ſent into England. A conſiderable quantity of linen and woollen cloths are likewiſe purchaſed for the ſame part of the kingdom.

LOCKEREN, a town of France, in the department of the Scheldt, and chief place of a canton, in the diſtrict of Termoude. The place contains 11,941, and the canton 15,693 inhabitants, on a territory of 70 kiliometres, in three communes.

LOCKHART, a town of North Carolina, in Albemarle Sound; 38 miles E.S.E. of Halifax. N. lat. 36° 2′. W. long. 76 56′.

LOCKI, or Laki, as the ſame orthography may be almoſt indifferently pronounced, is a name of Lakſhmi, the conſort of the Hindoo deity Viſhnu. See Lakshmi.

LOCKING-up, or Locking-*down*, denotes the operation of paſſing boats up or down through locks.

Locking *of Wheels*, in *Rural Economy*, the means of faſtening them ſo as to prevent their running too ſwiftly upon the horſes, when coming down ſteep hills. This is effected in various ways; as by chains, ſledges, friction, bars, &c. See Cart, Wheel, and Waggon.

LOCKMAN, in the Iſle of Man, the officer who executes the orders of the government, much like our under-ſheriff.

LOCKS, in the *Manege*, in French called *entravons*, are pieces of leather two fingers broad, turned round, and ſtuffed on the inſide, to prevent their hurting the paſtern of a horſe, round which they are clapped. An *entrance* is compoſed of two *entravons* joined by an iron chain, ſeven or eight inches long.

LOCKSPIT, among *Miners*, is the ſmall cut or trench, made with a ſpace of about a foot wide, to mark out the firſt lines of a work.

LOCKTEWACKI, in *Geography*, a town of Swediſh Lapland, on a lake; 65 miles W.N.W. of Pitea.

LOCLE, a town, or rather village, of Switzerland, in the principality of Neufchatel. La Chaux de Fond, another large handſome village lying in a broad valley which reaches to Franche Comte, is connected with Locle by a range of pleaſing cottages, ſkirting both ſides of the road. Both theſe villages, together with the diſtricts belonging to them, contain about 6000 inhabitants, diſtinguiſhed for their ſkill and induſtry in the mechanical arts. They carry on an extenſive traffic in lace, ſtockings, cutlery, and other articles of their own manufacture; but particularly excel in watch-making, and every branch of clock-work. All ſorts of workmen neceſſary for the completion of that buſineſs, ſuch as painters, enamellers, engravers, and gilders, are found in theſe villages; where, upon an average, about 40,000 watches are annually made. Several inhabitants of theſe villages have invented uſeful mathematical and aſtronomical inſtruments. The ſon of Droz, afterwards a reſident at Paris, exhibited in England ſeveral automatical figures of ſurpriſing conſtruction: one played upon the harpſichord, another drew landſcapes, and a third copied any word preſented to it, or wrote down whatever was dictated by any of the company.

LOCMAN, a mountain of Perſia, in the province of Khoraſan; 15 miles W. of Maruerrud.

LOCMINE', a town of France, in the department of Morbihan, and chief place of a canton, in the diſtrict of Pontivy; 10 miles S. of Pontivy. The place contains 9429, and the canton 11,233 inhabitants, on a territory of 180 kiliometres, in ſeven communes.

LOCO Rotondo, a town of Naples, in the province of Bari; 11 miles S.S.E. of Monopoli.

LOCONTAI, a town of Upper Siam; 60 miles N. of Perſelon.

LOCRI, Locrians, in *Ancient Geography*, a people who are ſaid to have derived their name from an ancient hero called "Locris," or "Locros," whoſe ſon Opus founded a town under his own name. Theſe people formed four diſtinct diviſions, with appropriate ſurnames, the three firſt of which, *viz.* Locri *ozoli*, Locri *epicnemidii*, and Locri *opuntiani*, were ſettled in Greece: the fourth diviſion, denominated *epizephyrii*, inhabited Magna Græcia, near the promontory of Zephyrium. The *ozoli* occupied a conſiderable extent of country W. of the Phocide, along the gulf of Corinth. The *epicnemidii* derived their name from mount Cnemis, about which they dwelt; the Maliac gulf being on the E., mount Oeta on the N., the Phocide on the W., and the Locri opuntiani on the S., whoſe territory was of ſmall extent. The *epizephyrii* were ſituated near the promontory of Zephyrium, and were diſtributed into two claſſes, diſtinguiſhed by their name and their ſituation. One diviſion embarked on the gulf of Corinth, and the other on the Ægean ſea. It is therefore poſſible that a colony of one of theſe branches might eſtabliſh themſelves in this part of Italy. Their town, "Locri Epizephyrii," was ſituated on a hill near the abovementioned promontory. Some ſay that it was founded at the ſame time with Cyzicus, under the reign of Tullus Hoſtilius, but Strabo dates its origin a little after Crotona and Syracuſe, about the year 757 before our era. It was very flouriſhing, when Dionyſius the younger, having been driven from Syracuſe, practiſed there all ſorts of violence. But the Locrians, having recovered their liberty, expelled the garriſon and took ample vengeance of the tyrant. Epherus, ſays Strabo, reports, that Zaleucus formed the laws of the Locrians from thoſe of Crete, Sparta, and Athens, one of which eſtabliſhed a conformity of puniſhment to crimes, whereas before they were arbitrary and depended upon the will of the judge. The Locrians had built upon the coaſt a temple of Proſerpine, which was pillaged by Pyrrhus when he carried his arms into Italy. The town was not better treated by the Roman garriſon, under the orders of Flaminius. In the year 539 of Rome the Locrians, having devoted themſelves to the Brutians and Carthaginians, by this conduct incenſed the Roman republic; ſo that they ſent troops againſt them and took their city in the year 549. A little after, however, they recovered their liberty. The ſequel of the hiſtory of the Locrians is not known; but an inſtance of their valour has been recorded which deſerves to be mentioned. In a war between them and the Crotoniates, 10,000 Locrians, with a few additional troops, defeated 130,000 of the enemy near the river Sagra; an event ſo marvellous, that it became proverbial in giving atteſtation to a fact thought incredible. Αλεθεςρα των επι Σαγρα; *i. e.* it is more true than the battle of Sagra.

Locri, or *Locres*, *Motta di Buzzano*, a town of Italy, in Brutium. It was founded, as we have already mentioned in the preceding article, by a colony of Greeks called Locrians.

LOCRIAN, in *Ancient Muſic*, the ſeventh ſpecies of the diapaſon. It was alſo called *hypodorian*, and *common*.

LOCULAMENTUM, in *Botany*, denotes a cell or partition, in a ſeed-pod, for the ſeed of a plant.

In ſome plants we only find one loculamentum in a pod; in ſome others two, three, or more.

LOCUS, Place, in the general ſenſe. See Place.

Locus, among *Ancient Muſicians*, was uſed to ſignify the interval between one degree of acuteneſs or gravity of ſound and another. The Greeks uſed the word τοπος in the ſame ſenſe, for the ſpace through which the voice moved. See Motion.

This motion the Greeks diſtinguiſhed into two kinds; one continued, συνεχη, the other disjunct, διαςηματικη. Inſtances of the firſt kind are in ſpeaking; of the ſecond, in ſinging; and this they called melodic motion, or what was adapted to ſinging. Ptolemy in like manner divides ſounds of unequal pitch, ψοφος ἀνισοτονος, into continued and diſcrete, and ſays the firſt kind are improper, and the ſecond proper, for harmony.

Ariſtides Quintilianus interpoſes a third kind of motion between the two here mentioned, ſuch as that of a perſon reciting a poem.

Locus, in *Rhetoric*, a topic, or head, whence arguments are brought to prove the queſtion in hand. Some of theſe are called *loci communes*, or common topics, as being common to all ſorts of argument; thus, whether a thing be poſſible or impoſſible, more or leſs than ſomething elſe, &c.

Beſides theſe, three others are mentioned by rhetoricians, *juſtum*, *utile*, and *honeſtum*; to which ſome add *jucundum*; but Voſſius will have this laſt to be comprehended under *utile*. See Topic.

Locus *geometricus* denotes a line, by which a local or indeterminate problem is ſolved. See Local *Problem.*

If a point vary its poſition, according to ſome determinate law, it will deſcribe a line, which is called its *locus*: or a locus is a line, any point of which may equally ſolve an indeterminate problem.

This, if a right line ſuffice for the conſtruction of the equation, is called *locus ad rectum*; if a circle, *locus ad circulum*; if a parabola, *locus ad parabolam*; if an ellipſis, *locus ad ellipſim*; and ſo of the reſt of the conic ſections.

The loci of ſuch equations as are right lines, or circles, the ancients called *plane* loci; and of thoſe that are parabolas, hyperbolas, &c. *ſolid* loci.

Apollonius of Perga wrote two books on *plane loci*, in which the object was, to find the conditions under which a point, varying in its poſition, is yet limited to have a right line, or a circle given in poſition. Theſe books are loſt, but attempts have been made at reſtorations by Schooten, Fermat, and R. Simſon; the treatiſe "De Locis Planis," of the latter geometer, publiſhed at Glaſgow, 1749, is a very excellent performance, in all reſpects worthy of its celebrated author. Beſides the above-mentioned writers, the doctrine of loci has been treated of by various other mathematicians, as Craig, Maclaurin, Des Cartes, De l'Hôpital, &c. the latter of whom has two chapters on this ſubject in his Conic Sections. Leſlie in his Geometry has alſo a chapter on plane loci, which contains ſeveral of the moſt ſimple and intereſting propoſitions of this kind.

Before we proceed to inveſtigate the loci of the higher orders, it will be proper to ſtate a few of the principal properties and uſes of plane or geometrical loci; in doing which, however, we muſt neceſſarily confine ourſelves to thoſe only of the moſt general deſcription, as the limits of this article will not admit of a minute and particular inveſtigation.

Prop. I.

If a ſtraight line, drawn through a given point to a ſtraight line given in poſition, be divided in a given ratio, the locus of the point of ſection is a right line given in poſition. *Plate* XII. *Analyſis, fig.* 1.

Let the point A, and the ſtraight line B D, be given in poſition, and let A B, limited by theſe, be cut in a given ratio at C; this point will be in a ſtraight line given in poſition.

Analyſis.—From A, let fall the perpendicular A D upon B D; and through C draw C E parallel to B D; then A C : A B : : A E : A D, and, conſequently, the ratio of A E to A D is given; but A D is given both in poſition and magnitude, and hence A E and the point E are alſo given, and therefore C E, which is perpendicular to A D, is given in poſition.

Compoſition.—Let fall the perpendicular A D, which divides E in the given ratio, and erect the perpendicular C E, ſo ſhall this ſtraight line be the locus required. For C E being parallel to B D, A C : A B : : A E : A D; that is, in the given ratio.

Prop. II.

If a ſtraight line, drawn through a given point to the circumference of a given circle, be divided in a given ratio, the locus of the point of ſection will alſo be the circumference of a given circle. *Fig.* 2.

Let A B, terminating in a given circumference, be cut in a given ratio, the ſegment A C will likewiſe terminate in a given circumference.

Analyſis.—Join A with D, the centre of the given circle; and draw C E parallel to B D; then it is evident that A C : A B : : A E : A D; whence the ratio of A E to A D being given, A E and the point E are given. Again, ſince A C : A B : : C E : B D, the ratio of C E to B D is given, and conſequently C E is given in magnitude. Wherefore the one extremity E being given, the other extremity of C E muſt trace the circumference of a given circle.

Compoſition.—Join A D, and divide it at E in the given ratio, and in the ſame ratio make D B to the radius E C, with which and from the centre E deſcribe a circle.

For draw A B cutting both circumferences, and join C E and B D. Becauſe C E : B D : : A E : A D, alternately C E : A E : : B D : A D; wherefore the triangles C A E and B A D, having likewiſe a common angle, are ſimilar; and conſequently, A C : C B : : A E : A D, that is, in the given ratio.

Prop. III.

If through a given point two ſtraight lines be drawn in a given ratio, and containing a given angle; ſhould the one terminate in a given circumference, the other will alſo terminate in a given circumference. *Fig.* 3.

Let the angle C A B, its vertex A, and the ratio of its ſides be given; if A B be limited by a given circle, the locus of C will alſo be a given circle.

Analyſis.—Join A with D, the centre of the given circle; draw A E at the given angle with A D, and in the given ratio; and join D B and E C. Becauſe the point A and the centre D are given, the ſtraight line A D is given; and ſince the angle D A E, being equal to B A C, is given; A E is given in poſition. But A D being to A E in the given ratio, A E muſt be given alſo in magnitude, and conſequently the point E is given. Again, the whole angle B A C being equal to D A E, the part B A D is equal to C A E, and becauſe A B : A C : : A D : A E, alternately A B : A D : : A C : A E; wherefore the triangles A D B and A E C are ſimilar, and hence A B : B D : : A C : C E, or alternately, A B : A C : : B D : C E; conſequently the fourth term C E is given in magnitude; and its extremity E being given, the other muſt lie in a given circumference.

Compoſition.—Having drawn A E at the given angle with A D, make A D to A E in the given ratio; and in the ſame ratio let D B be made to E C; a circle deſcribed from the centre E with the diſtance E C is the locus required.

For A D : A E : : D B : E C, and alternately, A D : D B : : A E : E C. But the angle B A D is equal to C A E; becauſe the whole B A C is equal to D A E; conſequently the triangles A B D and A C E are ſimilar; and A B : A D : : A C : A E, or alternately, A B : A C : : A D : A E; that is, in the given ratio.

Prop. IV.

The middle point of a given ſtraight line, which is placed between the ſides of a right angle, lies in the circumference of a given circle. *Fig.* 4.

Let A D be placed in the right angle E D F, touching E D and D B, the locus of its biſection C is a given circle.

Analyſis.—Join D C; then becauſe the baſe of the triangle A D B is biſected in C, a circle deſcribed from C as a centre, and with the radius A C, or C B, will paſs through the point D; for the angle A D B being a right angle, it neceſſarily falls in the circumference of the ſemicircle A D E ; conſequently A C, C B and C D, are all equal to each other. But A C, being half of A B, is given, therefore D C is alſo given, whence the locus of the point of biſection C is a circle deſcribed from D with the radius D C.

Compoſition.—From D, with a diſtance equal to half the given line, deſcribe a circle ; this is the locus required.

For draw the radius D C, make $AC = DC$, and produce A C to B. Becauſe $AC = DC$, the angle $ADC = DAC$; but the angles D A C and D B C are together equal to a right angle, and therefore equal to A D C and B D C ; whence the angle D B C is equal to the angle B D C, and, conſequently, the ſide D C is equal to B C. The ſegments A C, B C are thus each of them equal to D C, and hence A B is itſelf double D C, or is equal to the given ſtraight line.

Prop. V.

If from two given points there be inflected two ſtraight lines in a given unequal ratio, the locus of their point of concourſe is a given circle.

Let A C and B C, drawn from the points A and B, have a given ratio, but not that of equality ; then will C, the point of concourſe, lie in the circumference of a given circle. *Fig.* 5.

Analyſis.—Draw C D, making the angle B C D equal to B A C ; and meeting A B produced in D. The triangles D A C and D C B, having the angle at D common, and the angles at A and C equal, are evidently ſimilar ; and hence $AD : AC :: CD : CB$, and alternately, $AD : CD :: AC : CB$, that is, in the given ratio ; but $AD : CD :: CD : BD$, and conſequently, A D is to B D in the duplicate of the given ratio A D to C D, and which is therefore likewiſe given. Conſequently B D, and the point D, are given ; and B D being thence given, its extremity C muſt lie in the circumference of a circle deſcribed with that radius.

Compoſition.—Divide A B in the given ratio in E, and in the ſame ratio make E D to B D ; the circle deſcribed from the centre D, and with the radius D E, is the locus required.

For ſince $AE : EB :: ED : BD$, it follows that $AD : ED :: CD : ED$, or as $CD : BD$; hence the triangles D A C and D C B, thus having their ſides, which contain their common angle D, proportional, are ſimilar ; and therefore $AC : AD :: BC : CD$, or alternately, $AC : BC :: AD : CD$ or D E, that is, in the given ratio.

Prop. VI.

If two ſtraight lines, containing a given rectangle, be drawn from a given point at a given angle ; ſhould the one terminate in a ſtraight line given in poſition, the other will terminate in the circumference of a given circle. *Fig.* 6.

Let the point A, the angle B A C, and the rectangle under its ſides B A, A C, be given ; if the direction B D be given, then will the locus of C be a given circle.

Analyſis.—From A let fall the perpendicular A D upon B D ; draw A E, to contain with A D an angle equal to the given angle, and a rectangle equal to the given ſpace, and join C E.

Since A D is evidently given in poſition and magnitude, A E is likewiſe given in poſition and magnitude ; and the rectangle $AD \times AE$ being equal to $AB \times AC$, therefore $AD : AB :: AC : AE$; but the angle D A E is equal to B A C, and hence D A B is equal to E A C. Wherefore the triangles A B D, A E C, having each an equal angle, and the ſides containing it proportional, are ſimilar ; and conſequently the angle A C E is equal to the right angle A D B. Whence the locus C is a circle, having A E for its diameter.

Compoſition.—Having let fall the perpendicular A D, draw A E, making the angle D A E equal to the given angle, and the rectangles D A, A E, equal to the given ſpace. On A E as a diameter deſcribe a circle ; this is the locus required. For join C E, and the triangles D A B, E A C, being right-angled at D and C, and having the vertical angles at A equal, are evidently ſimilar ; and conſequently $AD : AB :: AC : AE$; and hence the rectangle $AB \times AC = AD \times AE$, that is, it is equal to the given ſpace.

The foregoing propoſition we have drawn with little variation from the chapter on loci given by profeſſor Leſlie in his Geometry, and ſeveral of the following propoſitions are likewiſe derived from the ſame ſource.

7. If a ſtraight line drawn from a given point to a ſtraight line given in poſition, contain a given rectangle, the locus of its point of ſection will be a given circle.

8. If two ſtraight lines in a given ratio, and containing a given angle, terminate in two diverging lines, which are given in poſition, the locus of their vertex will likewiſe be a right line given in poſition.

9. If from two points there be drawn two ſtraight lines, of whoſe ſquares the difference is given, the locus of their point of concourſe will be a right line given in poſition : or, which is the ſame, if the baſe of a triangle, and the difference of the ſquares of the two ſides be given, the vertex of the triangle will fall in a right line given in poſition.

10. If the baſe and vertical angle of a triangle be given, the locus of its vertex will be the circumference of a given circle.

11. If the difference of the ſides, and the radius of the inſcribed circle of a triangle be given, the locus of its vertex is a right line given in poſition.

12. If two given unequal perpendiculars be drawn to a right line given in poſition, and their oppoſite extremities be joined, the locus of the point of interſection will be a right line given in poſition.

13. If in any triangle the baſe be given, and the ſum of the ſquares of the other two ſides, the locus of the vertex is a given circumference.

14. If from given points there be drawn ſtraight lines, whoſe ſquares are together equal to a given ſpace, their point of concourſe will terminate in the circumference of a given circle.

15. If right lines be drawn from a given point to cut a given circle, and from the points of interſection there be taken, upon theſe lines, on either ſide, lines in a conſtant given ratio to the diſtance between the reſpective points of interſection and the given point ; the locus of the points, ſo determined, will be a circle.

16. If two circles cut each other, and through either point of interſection a right line be drawn, cutting both the circles, then, if a right line be always taken thereon from one of thoſe points in a given ratio to the part intercepted between the circles, the locus of the points ſo determined will be a circle.

17. If the circles cut each other as above, and a right line be drawn through either interſection, cutting both the circles, then if a right line be always taken thereon from one of thoſe points in a given ratio to the part between the other point and interſection, the locus of the point ſo determined will be a circle.

18. If triangles be inſcribed in a given ſegment of a circle, and from the vertex on either ſide (produced if neceſſary) there be taken, either way, a right line always in a conſtant ratio to either of the ſides, or to their ſum, or difference, the loci of the points ſo deſcribed will be circles.

The above contain many of the moſt ſimple caſes of geometrical loci; and we will now ſhew the application of them to the conſtruction of certain geometrical problems.

Of the Conſtruction of geometrical Problems.

Prob. I.

Having given the baſe, perpendicular, and vertical angle of a plane triangle; it is required to conſtruct it. *Fig.* 7.

Analyſis.—Suppoſe the thing done, and let A B C repreſent the propoſed triangle, of which the baſe A B, the perpendicular C D, and vertical angle A C B, are given; then it is obvious, in the firſt place, that the locus of the vertex will be the right line C F, drawn parallel to A B, at the given perpendicular diſtance. Alſo, ſince the angle A C B is given, the locus of the vertex will be in the circumference of the circle A C B, deſcribed upon A B, capable of containing the given angle A C B; and conſequently, at either point where the line and circle interſect each other, will be the vertex of the triangle required.

Conſtruction.—On the given baſe A B deſcribe a circle that ſhall contain the given vertical angle. And parallel to A B, and at a diſtance equal to the given perpendicular, draw the right line F C E; join A C, C B, ſo is A C B the triangle required. For, the point C being in the ſegment A C B, the angle A C B is equal to the given vertical angle; and being alſo in the line F C E, the perpendicular C D is equal to the given perpendicular, and the baſe A B is equal to the given baſe.

If the right line cut the circle in one point, it will alſo cut it in two points, and therefore in this caſe there are two triangles which anſwer the conditions of the problem; but if it touches the circle only, then there is but one ſuch triangle; and if the line F C E falls above the circle, then the problem is impoſſible.

Prob. II.

Having given the perimeter of a right-angled triangle, and the perpendicular let fall from the right angle to the oppoſite ſide, to conſtruct it. *Fig.* 8.

Analyſis.—Suppoſe the thing done, and let A C B be the propoſed triangle; produce the line A B both ways to D and E, making A D = A C, and C B = B E; then will D E repreſent the perimeter which is given by the queſtion; join D E and C E. Then becauſe D A = A C, the angle A D C = D C A; but the angle C A B is equal to the two angles A D C and D C A, or it is equal to double the angle D C A: in the ſame manner it may be ſhewn that the angle A B C is equal to double the angle B C E; but the angles C A B and A B C are together equal to a right angle, and conſequently, ſince theſe are double of the angles D C A and B C E, it follows, that the ſum of the latter two angles is given, being equal to half a right angle; and therefore alſo the whole angle D C E is given, being equal to a right angle and half a right angle; therefore the locus of the point C is in the circumference of a given circle. And ſince the perpendicular C G is alſo given, the locus of the point C is the right line C F, parallel to the baſe A B, whence the point C is determined, being found in the interſection of the right line C F and the given ſegment D C E.

Conſtruction.—On the right line D E, equal to the given perimeter, deſcribe a ſegment capable of containing an angle equal to a right angle and half a right angle; and parallel to D E, and at the given perpendicular diſtance, draw the right line F C cutting the ſegment in C and C′: join D C, C E; and from C draw alſo C A, A B, making the angles D C A and B C E reſpectively equal to the angles C D A and C E B, ſo ſhall A C B be the triangle required.

For ſince the angle D C A is equal to the angle D A C, the ſide D A is equal to A C, and for the ſame reaſon the ſide C B is equal to B E, and therefore the three ſides of the triangle A B C are equal to the whole D E, or to the given perimeter; alſo, ſince the angle D C E is equal to a right angle and half a right angle, the angles C D A and C E B are together equal to half a right angle; but the angle C A B is double the angle C D A, and the angle C B A is double the angle C E B, and conſequently theſe two together are equal to a right angle; therefore the third angle of the triangle A C B is a right angle. Hence, ſince the perpendicular C G is equal to the given perpendicular, by conſtruction, and the ſum of the three ſides A B, A C, B C, equal to the given perimeter, and the angle A C B equal to the given angle, it follows that the triangle A B C is that which was to be conſtructed.

This conſtruction ſerves equally for any other triangle, provided the vertical angle be given: and the limits of poſſibility are the ſame as in the preceding problem.

We will add one other example from Dr. Pemberton's paper on this ſubject, printed in vol. liii. of the Philoſophical Tranſactions, and will then proceed to the conſideration of loci of the higher orders.

Prob. III.

Let it be propoſed to draw a triangle given in ſpecies, ſo that two of its angles may touch a right line given in poſition, and the third angle a given point.

This problem, which would be extremely difficult to ſolve algebraically, admits of more than one very conciſe geometrical ſolution; and as they will occupy but little ſpace, it is preſumed they will not be unacceptable to the reader of this article.

In the firſt place, ſuppoſe a circle (*fig.* 9.) to paſs through the three points A, E, D, which ſhall interſect A C in G. Then E G, D G, being joined, the angle D E G will be equal to the given angle D A C, both inſiſting on the ſame arc D G: alſo the angle E D G is the complement to the two right ones of the given angle B A C: theſe angles therefore are given, and the whole figure E F G D given in ſpecies. Conſequently the angle E G F, and its equal A D E will be given, together with the ſide D E of the triangle in poſition.

Again, ſuppoſe a circle (*fig.* 10.) to paſs through the three points A, E, F, cutting A D in H, and E H, F H joined. Here the angle E F H will be equal to the given angle E A H; and the angle F E H equal to the given angle F A H. Therefore the whole figure E H F D is given in ſpecies; and conſequently the angle A D E as before.

Laſtly, ſuppoſe a circle (*fig.* 11.) to circumſcribe the triangle, and interſect one of the lines, as A C in I. Then D I being drawn, the angle D I F will be equal to the given angle D E F in the triangle; conſequently D I is inclined to A C in a given angle, and is given in poſition, as alſo the point I given; whence I E being drawn, the angle F I E will be the complement of the angle E D F in the triangle to two right ones. Therefore I E is given in poſition, and by its interſection with the line A B, gives the point E, with the poſition of D E, and thence the whole triangle as before. Here it may be obſerved, that the angle D of the triangle E D F, given in ſpecies touching a given point D, and another of its angles touching A C, the line A E here found is the locus of the third angle E.

Of the higher Order of Loci.

Loci are very commodiouſly divided into orders, according to the dimenſions to which the variable quantity riſes in the formula which expreſſes the equation of the curve.

Thus it will be a *locus of the firſt order*, if the equation be $x = a y$; a *locus of the ſecond* or quadrate order, if $y^2 = a x$, or $y^2 = a^2 - x^2$, &c.; a *locus of the third* or cubic order, if $y^3 = a^2 x$, or $y^3 = a x^2 - x^3$, &c.

The better to conceive the nature of the locus, ſuppoſe two unknown and variable right lines A P, P M (*figs.* 12 and 13.) making any given angle A P M with each other; the one whereof, as A P, we call x, having a fixed origin in the point A, and extending itſelf indefinitely along a right line given in poſition; the other P M, which we call y, continually changing its poſition, but always parallel to itſelf; and moreover an equation only containing theſe two unknown quantities x and y, mixed with known ones, which expreſſes the relation of every variable quantity A P (x) to its correſpondent variable quantity P M (y): the line paſſing through the extremities of all the values of y, *i. e.* through all the points M, is called a geometrical locus, in general, and the locus of that equation in particular.

All equations, whoſe loci are of the *firſt order*, may be reduced to ſome one of the four following formulæ:

$$1 \cdot y = \frac{b x}{a},\ 2 \cdot y = \frac{b x}{a} + c \cdot 3 \cdot y = \frac{b x}{a} - c \cdot 4 \quad y = c - \frac{b x}{a},$$

where the unknown quantity y is ſuppoſed always to be freed from fractions, and the fraction that multiplies the other unknown quantity x to be reduced to this expreſſion $\frac{b}{a}$, and all the known terms to this c.

The locus of the firſt formula being already determined; ſince it is evident, that it is a right line which cuts the axis in A, and which makes with it an angle, ſuch that the two unknown quantities x, y, may be always to one another in the proportion of a to b; to find that of the ſecond, $y = \frac{b x}{a} + c$. In the line A P (*fig.* 14.) take A B $= a$, and draw B E $= b$, A D $= c$, parallel to P M. On the ſame ſide A P, draw the line A E of an indefinite length towards E, and the indefinite ſtraight line D M parallel to A E. I ſay the line D M is the locus of the aforeſaid equation or formula; for if the line M P be drawn from any point M thereof parallel to Q A, the triangles A B E, A P F, will be ſimilar; and therefore A B (a) : B E (b) : : A P (x) : P F $= \frac{b x}{a}$; and conſequently P M (y) $=$ P F $\left(\frac{b x}{a}\right)$ $+$ F M (c).

To find the locus of the third form, $y = \frac{b x}{a} - c$, proceed thus. Aſſume A B $= a$ (*fig.* 15.) and draw the right lines B E $= b$, A D $= c$, parallel to P M, the one on one ſide A P, and the other on the other ſide; and through the points A, E, draw the right line A E of an indefinite length towards E, and through the point D the line D M parallel to A E: I ſay, the indefinite right line G M ſhall be the locus ſought; for we ſhall have always P M (y) $=$ P F $\left(\frac{b x}{a}\right)$ $-$ F M c.

Laſtly, to find the locus of the fourth formula, $y = c - \frac{b x}{a}$; in A P (*fig.* 16.) take A B $= a$, and draw B E $= b$, A D $= c$, parallel to P M, the one on one ſide A P, and the other on the other ſide; and through the points A, E, draw the line A E indefinitely towards E, and through the point D draw the line D M parallel to A E. I ſay D G ſhall be the locus ſought; for if the line M P be drawn from any point M thereof, parallel to A Q, then we ſhall have always P M (y) $=$ F M (c) $-$ P F $\left(\frac{b x}{a}\right)$.

Hence it appears, that all the loci of the *firſt* degree are ſtraight lines; which may be eaſily found, becauſe all their equations may be reduced to ſome one of the foregoing formulæ.

All loci of the *ſecond* degree are conic ſections, *viz.* either the parabola, the circle, ellipſis, or hyperbola: if an equation therefore be given, whoſe locus is of the ſecond degree, and it be required to draw the conic ſection, which is its locus, firſt draw a parabola, ellipſis, and hyperbola; ſo that the equations expreſſing the natures thereof may be as compound as poſſible; in order to get general equations, or formulæ, by examining the peculiar properties whereof we may know which of theſe formulæ the given equation ought to have regard to; that is, which of the conic ſections will be the locus of the propoſed equation. This known, compare all the terms of the propoſed equation with the terms of the general formula of that conic ſection, which you have found will be the locus of the given equation; by which means you will know how to draw the ſection, which is the locus of the equation given.

For example: let A P (x), P M (y), be unknown, and variable ſtraight lines (*fig.* 17.), and let m, n, p, r, s, be given right lines: in the line A P take A B $= m$, and draw B E $= n$, A D $= r$, parallel to P M; and through the point A draw A E $= e$, and through the point D the indefinite right line D G parallel to A E. In D G take D C $= s$, and with C G, as a diameter, having its ordinates parallel to P M, and the line C H $= p$, as the parameter, deſcribe a parabola C M, and it will be the locus of the following general formula:

$$\begin{aligned} y^2 - \frac{2n}{m} x y + \frac{n^2}{m^2} x^2 - 2 r y + \frac{2 n r}{m} x - r^2 &= 0. \\ - \frac{e p}{m} x + p s.& \end{aligned}$$

For if from any point M there be drawn the right line M P, making any angle A P M with A P; the triangles A B E, A P F, ſhall be ſimilar; therefore A B (m) : A E (e) : : A P (x) : A F, or D G $= \frac{e x}{m}$; and A B (m) : B E (x) : : A P (x) : P F $= \frac{n x}{m}$. And conſequently, G M or P M

— P F

$- \text{P F} - \text{F G} = y - \frac{nx}{m} - r$, and C G or D G − D C = $\frac{ex}{m} - s$. But from the nature of the parabola $\text{G M}^2 = \text{C G} \times \text{C H}$; which equation will become that of the general formula, by putting the literal values of thoſe lines.

Again: if through the fixed point A you draw the indefinite right line A Q (*fig.* 18.) parallel to P M, and take A B = m, and draw B E = n, parallel to A P, and through the determinate points A E, the line A E = e; and if in A P you take A D = r, and draw the indefinite ſtraight line D G parallel to A E, and take D C = s; this being done, if with the diameter C G, whoſe ordinates are parallel to A P, and parameter the line C H = p, you deſcribe a parabola C M; this parabola ſhall be the locus of this ſecond equation, or formula:

$$x^2 - \frac{2n}{m} y x + \frac{n^2}{m^2} y^2 - 2 r x + \frac{2nr}{m} y + r^2 = 0.$$

$$- \frac{ep}{m} y + ps.$$

For if the line M Q be drawn from any point M, therein, parallel to A P; then will A B (m) : A E (e) : : A Q or P M (y) : A F or D G = $\frac{ey}{m}$. And A B (m) : B E (n) : : A Q (y) : Q F = $\frac{ny}{m}$. And therefore G M or Q M − Q F − F G = $x - \frac{ny}{m} - r$; and C G or D G − D C = $\frac{ey}{m} - s$. And ſo by the common property of the parabola, you will have the foregoing ſecond equation, or formula. So likewiſe may be found general equations, or formulæ, to the other conic ſections.

Now if it be required to draw the parabola, which we find to be the locus of this propoſed equation $y^2 - 2ay - bx + c^2 = 0$; compare every term of the firſt formula with the terms of the equation, becauſe y^2 in both is without fractions; and then will $\frac{2n}{m} = 0$, becauſe the rectangle xy not being in the propoſed equation, the ſaid rectangle may be eſteemed as multiplied by 0; whence $n = 0$, and $m = e$; becauſe the line A E falling in A B, that is, in A P in the conſtruction of the formula, the points B, E, do coincide. Therefore, deſtroying all the terms affected with $\frac{n}{m}$ in the formula, and ſubſtituting m for e, we ſhall get $y^2 - 2ry - px + r^2 + ps = 0$.

Again, by comparing the correſpondent terms $-2ry$, and $-2ay$, as alſo $-px$, and $-bx$, we have $r = a$, and $p = b$; and comparing the terms wherein are neither of the unknown quantities x, y, we get $r^2 + ps = c^2$; and ſubſtituting a and b for r and p, then will $s = \frac{c^2 - a^2}{b}$, which is a negative expreſſion, when a is greater than c, as is here ſuppoſed. There is no need of comparing the firſt terms y^2 and y^2, becauſe they are the very ſame. Now the values of m, n, r, p, s, being thus found, the ſought locus may be conſtructed by means of the conſtruction of the formula, and after the following manner.

Becauſe B E (n) = 0 (*fig.* 19.) the points B, E, do coincide, and the line A E falls in A P; therefore through the fixed point A draw the line A D $r = a$ parallel to P M, and draw D G parallel to A P, in which take D C (s) = $\frac{a^2 - c^2}{b}$; then with D C, as a diameter, whoſe ordinates are right lines parallel to P M, and parameter the line C H (p) = b, deſcribe a parabola: I ſay, this will be the locus of the given equation, as is eaſily proved. If in a given equation, whoſe locus is a parabola, x^2 be without a fraction; then the terms of the ſecond formula muſt be compared with thoſe of the given equation.

Thus much for the method of conſtructing the loci of equations which are conic ſections. If, now, an equation, whoſe locus is a conic ſection, be given, and the particular ſection whereof it is the locus, be required:

All the terms of the given equation being brought over to one ſide, ſo that the other be equal to 0, there will be two caſes.

Caſe 1. When the rectangle xy is not in the given equation. 1. If either y^2 or x^2 be in the ſame equation, the locus will be a parabola. 2. If both x^2 and y^2 are in the equation with the ſame ſigns, the locus will be an ellipſis, or a circle. 3. If x^2 and y^2 have different ſigns, the locus will be an hyperbola, or the oppoſite ſections regarding their diameters.

Caſe 2. When the rectangle xy is in the given equation. 1. If neither of the ſquares x^2 or y^2, or only one of them, be in the ſame, the locus of it will be an hyperbola between the aſymptotes. 2. If y^2 and x^2 be therein, having different ſigns, the locus will be an hyperbola, regarding its diameters. 3. If both the ſquares x^2 and y^2 are in the equation, having the ſame ſigns, then, according as the co-efficient of x^2 is greater, equal or leſs than the ſquare of half the co-efficient of xy, the locus ſhall be an ellipſe, parabola, or hyperbola. And in any caſe the locus of the equation is ſome conic ſection.

We will add a problem or two, by way of illuſtration, with which we muſt conclude this article.

Problem I.

If A B be the axis of a conic ſection, from B draw B D to meet the curve in D; and erect D C perpendicular to A B, and produce it from C till C P is in a given ratio to B D; the locus of the point P will be a conic ſection.

1. For the ellipſe (*fig.* 20.); put the axis A B = a, and its conjugate Q O E = b, B C = x, and the ratio B D : C P : : $d : a$. Then by the known property of the ellipſe,

$$a^2 : b^2 : : ax - x^2 : \text{C D}^2 = \frac{b^2}{a^2}(ax - x^2);$$

conſequently, $\text{B D}^2 = \frac{b^2 ax}{a^2} - \frac{b^2}{a^2}x^2 + x^2 = \frac{b^2 ax}{a^2} + \frac{a^2 - b^2}{a^2}x^2$, and, therefore, $\text{C P}^2 = \frac{a^2}{d^2} + \text{B D}^2 = \frac{b^2 ax + (a^2 - b^2)x^2}{d^2} = \frac{a^2 - b^2}{d^2}\left(\frac{b^2 a}{a^2 - b^2}x - x^2\right)$, which, if a be greater than b, is an equation to the hyperbola, the axes of which are $\frac{b^2 a}{a^2 - b^2}$ and $\frac{b^2 a}{d\sqrt{(a^2 - b^2)}}$.

And if b be greater than a, the equation becomes

$$C\,P^2 = \frac{b^2 a x - (b^2 - a^2)\,x^2}{d^2} =$$

$$\frac{b^2 - a^2}{d^2}\left\{\frac{b^2 a}{b^2 - a^2}\,x - x^2\right\}$$

which is an equation to the ellipſe whoſe axes are

$$\frac{b^2 a}{b^2 - a^2} \text{ and } \frac{b^2}{d\sqrt{(b^2 - a^2)}}.$$

Again, if $b = a$, the ellipſe becomes a circle, and the equation for the value of C P becomes $C\,P^2 = \frac{b^2 a x}{d^2}$, which is an equation to the parabola, whoſe parameter is $\frac{b^2 a}{d^2}$.

1. For the hyperbola (*fig.* 21.); the ſame notation remaining, $D\,C^2 = \frac{b^2}{a^2}\,a x + \frac{b^2}{a^2}\,x^2$ by the property of the curve; conſequently $C\,P^2 = \frac{a^2}{d^2} \times B\,D^2 =$

$$\frac{b^2}{d^2}\,a x + \frac{+b^2}{d^2}\,x^2 =$$

$$\frac{a^2 + b^2}{d^2}\left\{\frac{b^2 a x}{a^2 + b^2} + x^2\right\}$$

which expreſſes an equation to an hyperbola, whoſe axes are $\frac{b^2 a}{a^2 + b^2}$ and $\frac{b^2}{d\sqrt{(a^2 + b^2)}}$.

3. For the parabola (*fig.* 22.); put the parameter $= p$, then $C\,D^2 = p\,x$, and $B\,D^2 = p\,x + x^2$; therefore $C\,P^2 = \frac{a^2}{d^2}(p\,x + x^2)$ the equation to an hyperbola whoſe axes are p and $\frac{a p}{d}$.

Prob. II.

If on any given right line, A B, there be taken any variable diſtance A L, and from L, in the ſame direction, any given invariable diſtance L M; and if with the centres L and B, and radii L A, B M, arcs be deſcribed, it is required to determine the nature of the curve, which is the locus of P, the point of interſection.

Let $A\,B = a$ (*fig.* 23); $L\,M = b$; $B\,M = B\,P = \phi$, and having drawn P O perpendicular to A B, put $B\,O = x$. Then $B\,L = \phi + b$; $L\,O = \phi + b - x$; $L\,P = A\,L = a - b - \phi$; and becauſe $L\,P^2 - L\,O^2 = B\,P^2 - B\,O^2$, we have in ſymbols $(a - b - \phi)^2 - (\phi + b - x)^2 = \phi^2 - x^2$; whence $a^2 - 2\,(a - x)\,b = \phi^2 + 2\,(a - x)\,\phi$; and adding $-\,b^2 + b^2 + (a - x)^2$ to one ſide, and its equal $(a - x)^2$ to the other ſide, there reſults $a^2 - b^2 + (a - b - x)^2 = (a - x + \phi)^2$.

Now take $A\,C = L\,M = b$, draw C D perpendicular to A B, and make $A\,D = A\,B = a$; then $C\,D^2 = a^2 - b^2$; $C\,O^2 = (a - b - x)^2$, and $(O\,A + B\,P)^2 = (a - x + \phi)^2$ whence we have $D\,O = A\,O + P\,B$; or $P\,B = D\,O - A\,O$.

Hence it will be eaſy to derive an algebraical equation for the rectangular co-ordinates of the curve; for we have only to put $P\,O = y$, to ſubſtitute $\sqrt{(x^2 + y^2)}$ for ϕ, and to clear the equation of radicals. The equation thus found will ſhew the curve to be of the fourth order; but the curve and its principal properties may be more readily deduced from the property above inveſtigated; *viz.* $P\,B = D\,O - A\,O$. The curve will conſiſt of two equal and ſimilar parts, lying on different ſides of A B, it will be a ſort of oval, encloſing the point B on every ſide.

The following are ſome of the ſimpleſt caſes of the higher order of loci.

1. The baſe, and ſum of the ſides of a plane triangle being given, the locus of its vertex is an *ellipſe.*

2. The baſe and difference of the ſides of a plane triangle being given, the locus is an *hyperbola.*

3. The locus of that point, from which, if perpendiculars be drawn to three right lines given in poſition, and ſuch that the ſum of their ſquares ſhall be equal to a given ſpace, is an *ellipſe.*

And the ſame is true, whatever be the number of lines given in poſition.

4. If a triangle given in ſpecies have two of its angles upon a ſtraight line given by poſition, and the ſide adjacent to thoſe angles paſſing through a given point, the locus of the angle, oppoſite that ſide, is an *hyperbola.*

5. Let A, B, be two given points in the right line A B, given in poſition; let C, D, be two given points without that line; and alſo let C V, D V, be drawn meeting in F and G, ſo that the rectangle A F × B G is given, the locus of the point will in all caſes be a *conic ſection:*

6. Let A B be a given ſtraight line, and P a given point without it; let C P D be drawn, meeting A B in C; and let C P be to P D as A C to C B; the locus of the point D is a given *hyperbola.*

7. When the baſe of a triangle is given, and one of the angles at the baſe doubles the other, the locus of the vertex is an *hyperbola.*

8. The locus of the angles of parallelograms, formed by drawing tangents at the vertices of any two conjugate diameters of an ellipſe, is alſo an *ellipſe cocentric with the former.*

The above caſes, and ſeveral other curious properties of this kind, the reader will find inveſtigated in Leybourn's "Mathematical Repoſitory."

The method of conſtructing geometrical loci, by reducing them to equations as compound as poſſible, we owe to Mr. Craig, who firſt publiſhed it in his Treatiſe of the Quadrature of Curves, 1693. It is explained at large in the ſeventh and eighth books of the Conic Sections of the marquis de l'Hoſpital. This ſubject is particularly illuſtrated in Maclaurin's Algebra, part iii. See alſo Des Cartes's Geometry; Stirling's Illuſtratio Linearum Tertii Ordinis; De Witt's Elementa Curvarum: Bartholomæus Juliari, in his Aditus ad nova Arcana Geometrica delegenda, has ſhewn how to find the loci of equations of the higher order. See alſo the other writers mentioned in the preceding part of this article.

LOCUST, Locusta, in *Entomology*, a genus of inſects, referred to that of *gryllus;* which ſee.

Under that article the reader will find a particular account of the devaſtations occaſioned by ſwarms of locuſts in their marches, and he will perceive the propriety of the frequent alluſions to them that occur in the ſacred writings. Dr. Shaw, Niebuhr, Ruſſell, and many other travellers into the eaſtern countries, repreſent their taſte as agreeable, and inform us that they are frequently uſed for food. Dr. Shaw obſerves, that when they are ſprinkled with ſalt and fried, they are not unlike, in taſte, to our freſh-water cray-fiſh. Ruſſell ſays, that the Arabs ſalt them, and eat them as a delicacy. We learn alſo from Niebuhr, that they are gathered by the Arabs in great abundance, dried, and kept for winter proviſion. Hence we may naturally ſuppoſe, that theſe locuſts were the food of John the Baptiſt.

Locust, *Water*, *Locuſta Aquatica*, the name given by authors to a ſpecies of water-inſect, ſomewhat reſembling the locuſt kind in ſhape. It is about three inches long, its tail an inch and quarter, and its legs are of different lengths, the anterior part being the ſhorteſt of all; its body is ſlender, and its fore-legs are always carried ſtraight forward, ſo as to reach beyond the head in the form of antennæ; theſe, as well as the other legs, end each in two claws; the eyes are ſmall, and not very prominent, and the upper wings are cruſtaceous; the under ones membranaceous, thin, and tranſparent; the middle joint of the leg is ſuch, that the creature can only move them upwards, not downwards, and there runs an acute tongue or proboſcis under the belly, as is the caſe in the water-ſcorpion and notonecta. See Nepa *Linearis*.

Locust, in *Botany*. See Ceratonia *Siliqua*. See alſo Gleditsia and Hymenæa.

LOCUSTA. See Valeriana.

Locusta-*Pulex*, a name given by Swammerdam to a genus of inſects, deſcribed ſince by Mr. Ray under the name *cicadula*.

LOCUSTÆ is uſed by botaniſts for the tender extremities of the branches of trees; ſuch as, according to the erroneous ſuppoſition of ſome, John the Baptiſt fed on in the wilderneſs.

Some alſo uſed locuſtæ for the beards and pendulous ſeeds of oats, and of the gramina paniculata; to which the name is given on account of their figure, which ſomething reſembles that of a locuſt.

LOCUSTELLA, the *Graſs-hopper Lark*, in *Ornithology*, the name of a ſmall bird of the lark kind, the Alauda *Trivialis* of Linnæus; which ſee.

LOCUTIUS, in *Mythology*, the god of ſpeech among the Romans, called by Livy Aius *Locutius*; which ſee.

LOCUTORIUM. The monks and other religious in monaſteries, after they had dined in their common hall, had a withdrawing room, where they met and talked together among themſelves, which room, for that ſociable uſe and converſation, they called *locutorium*, *a loquendo*; as we call ſuch a place in our houſes parlour, from the French *parler*; and they had another room, which was called *locutorium forinſecum*, where they might talk with laymen.

LODARIA, in *Geography*, a town of Hindooſtan, in Bahar; 24 miles N.N.E. of Hajypour.

LODDIGESIA, in *Botany*, is juſtly devoted by Dr. Sims in Curtis's Magazine, to commemorate the merits of a moſt excellent and ſcientific cultivator of plants, whoſe liberality is equal to his knowledge, Mr. Conrad Loddiges of Hackney. Curt. Mag. v. 24. 965. Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Eſſ. Ch. Standard many times ſmaller than the wings or keel. Filaments all in one ſet, with a dorſal fiſſure. Legume ſtalked, turgid.

1. L. *oxalidifolia*. Oxalis-leaved Loddigeſia. Curt. Mag. t. 965.—The only known ſpecies, a native of the Cape of Good Hope, from whence its ſeeds were firſt received by George Hibbert, eſq. The plant is tolerably hardy in the conſervatory, readily propagated by cuttings, and flowers freely in May and June. Mr. Loddiges himſelf has alſo raiſed it, many years ago, from Cape ſeeds. The *ſtem* is ſhrubby, low, much branched. *Leaves* ſcattered, ſtalked, ternate, inverſely heart-ſhaped, rather glaucous, ſmooth, tipped with a minute point. *Stipulas* intrafoliaceous, ſmall, ſetaceous, deciduous. *Cluſters* terminal, ſomewhat umbellate, of few flowers. *Bracteas* ſmall, ſlender, almoſt capillary. *Calyx* nearly bell-ſhaped, obtuſe at the baſe, coloured, ſmooth, its three lower teeth rather the longeſt. *Standard* white, not twice the length of the calyx. *Wings* and *keel* about thrice as long as the ſtandard, white, the fore part of the keel violet. *Style* bent upward at a right angle. *Stigma* ſimple. *Legume* ſtalked, ovate, oblique, pointed, turgid, ſmooth. *Seeds* about four, kidney-ſhaped.

LODDON, in *Geography*, a ſmall market-town in the hundred to which it gives name, in the county of Norfolk, England, is ſituated 111 miles from London, on the banks of a ſmall ſtream, which, riſing near Howe in Clavering, falls into the Yare at Hardley Croſs. The church, which is a handſome ſtone ſtructure, with a fine tower, was erected near the end of the fifteenth century, at the ſole expence of ſir James Hobart, the attorney-general to king Henry VII., and afterwards chief juſtice of the common pleas, who was a great benefactor to this town and its vicinity. In the church are ſeveral memorials of the Hobart family. In the eaſt window was a piece of ſtained glaſs, now removed, repreſenting ſir James and his lady, with a ſketch of the church, and an appropriate inſcription. Loddon was returned, in the year 1800, as containing 166 houſes and 799 inhabitants. A market is held on Fridays, and two fairs annually. Blomfield's Hiſtory, &c. of Norfolk, 11 vols. 8vo.

LODE, a town of the iſland of Sardinia; 80 miles N. of Cagliari.

Lode, in *Inland Navigation*, ſignifies a cut or reach of water.

Lode, in *Mining*. This word is derived from the Anglo-Saxon, according to Dr. Pryce, and is uſed by the Corniſh miners to deſignate any regular vein, whether metallic or not. More commonly, however, it means a metallic vein.

The lodes that are found to contain tin and copper ores, in Cornwall and Devon, have their general direction in a line running nearly eaſt and weſt; their dip or *underlay* being more commonly to the north; though ſome which incline to the ſouth have been very productive. Veins which interſect the eaſt and weſt lodes are called *croſs-lodes*, or *croſs-courſes*, when their direction is nearly at right angles with the others; and *caunters*, more generally, when their direction is oblique.

The metallic eaſt and weſt lodes are traverſed or diſturbed by the croſs-courſes, and theſe interruptions are known by the name of *heaves*, which take place to very different degrees of extent, and vary much in the circumſtances under which they are found; ſo that miners do not agree upon any certain rules for determining the diſtance or direction of the heave by the accompanying appearances.

Though copper and tin are found but partially in croſs-lodes, yet lead has been raiſed in large quantities from ſome that have nearly a due north and ſouth courſe; ſuch as the Beeralſtone lead-mines and Wheal Betſy lead-mine in Devon. Eaſt and weſt lodes have ſometimes a mixture of lead ores with copper; but this appears to be derived from the interſection of a croſs-courſe, or the effect of a later depoſit. Lodes traverſe all kinds of rock found in the line of their direction, whether vertically or horizontally. Thoſe worked in Cornwall and Devon are chiefly in killas or grauwacke ſlate; but they are ſometimes in granite, and paſs not unfrequently from the former into the latter.

The width of veins varies from an inch or two to fifteen or twenty feet; the latter dimenſion being rare, as the former is unprofitable to follow, unleſs in the expectation of an enlargement. The more common width, or, as the miners call it, *the ſize of lodes*, is from two to four feet; and if ſuch a vein as this be fully impregnated with metal, it is very profitable to work, and is called a good *courſe of ore.* The variations of width take place not only in diſtinct veins, but in one and the ſame; which, together with the fluctuations in the nature of their contents, render their produce ſo uncertain. A large and productive lode often dwindles to a mere *branch*, requiring an experienced eye to diſtinguiſh it from the rock through which it paſſes; and this again expands to a conſiderable ſize, filled with depoſits of various kinds. The width of lodes ſeems often to have a relation to the nature of the rock in which they are found; and changes in the latter appear generally to produce changes in the former. Thus, a vein that is large and productive in ſoft blue killas, will, by paſſing into harder, become leſs in ſize, and barren as to metallic contents. Another lode may be rich in hard ground, but poor and unproductive in that which is of a ſofter kind: but this is not ſo frequent as the former caſe. The depoſits of metal are as irregular in the lodes as the widths of them; and ſo much ſo, as to render the profits of mining proverbially uncertain. Ore is generally found to occupy certain parts of the veins only, differing conſtantly in extent, whether the length or depth on the courſe of the vein be conſidered, or the portion of its width which is filled up by it. No lode has been found regularly impregnated with metal to any great extent; and therefore, when ore is found, it is in what the miners aptly call *bunches* or *ſhoots*. The unproductive parts of veins, even in the moſt profitable mines, generally far exceed in extent the productive parts; but that mine is conſidered to be rich, which has either frequent or extenſive ſhoots of ore: the great art of the miner, therefore, conſiſts in tracing and working the valuable accumulations of the metals with as little waſte of labour and expence on the poorer ground as poſſible.

Although the bunches of ore have no regular form in their vertical or horizontal extent, yet the tendency to a certain direction or dip in the lode may be obſerved in each bunch or ſhoot of ore. Theſe ſhoots are frequently parallel in the ſame vein; and where the dip or underlay of the lode is to the north, the ſhoots of ore may frequently be obſerved to dip weſt in the lode. In veins underlaying ſouth, the bunches of ore frequently have their dip to the eaſt: but this is not to be taken as a general rule, as many mines afford exceptions to it; the underlay of the lode and the dip of the bunches of ore being reverſed.

Theſe tendencies or inclinations of the depoſits of metal in the veins, connected with the ſituations, dips, and bearings of the veins themſelves, ſeem to offer grounds for argument on the diſputed queſtion of the mode in which the metals were depoſited; but they have not much, we believe, attracted the notice of mineralogiſts.

Lodes continue to indefinite lengths, and to unknown depths. It is very difficult to determine whether the end of any regular vein has been found or not; as there are many inſtances of their having become ſo ſmall as to be ſcarcely viſible, and yet afterwards, on purſuing them, to have reſumed their uſual ſize. When a lode has continued ſmall, either in length or depth, to any conſiderable extent, it is moreover uſually abandoned as unpromiſing; and thus complete evidence as to this queſtion is not obtained.

Lodes are perfect in the ſurface of the mountains, as well as in their greater depths; and may be traced uniformly by removing the ſoil with which the rock is covered. This is done conſtantly by the miner when he is about to undertake operations upon a newly diſcovered vein. This proceſs is called *coſteening*, or *ſhoding*. The width of a lode at the ſurface is no certain indication of its ſize in depth; as, when large at the ſurface, they are ſometimes found to become ſmall as they are purſued downwards; and, on the other hand, veins of moderate width *at graſs* have been found, at 40 or 50 fathoms deep, of great ſize.

The dip or inclination of lodes is ſeldom uniform. The common *underlay* is from one to four feet in a fathom of depth; but inſtances occur of a much greater inclination. The lodes that incline much from the perpendicular are not eſteemed ſo promiſing as thoſe which have a direction more downright; and it is a favourable ſymptom when a lode, from an oblique direction, is found to turn downwards. On the contrary, where bunches of ore *fail*, or become poor, in ſinking on them, it may often be obſerved that the vein *goes away flat*, as miners expreſs it. Thus it will be underſtood, that not only are the dips different in ſeparate lodes, but that the ſame vein frequently varies in this reſpect. Lodes have been obſerved to change their underlay, that is, from dipping to the north, to become perpendicular, and even turn to the ſouth. This is not, however, a matter of frequent occurrence.

The underlay of lodes muſt be aſcertained, when it is intended to ſink perpendicular ſhafts to meet them at certain required depths; and from this is determined the diſtance to be ſet out north or ſouth from the back of the vein, for commencing ſuch ſhafts.

Shafts are often ſunk *upon* the lodes, and of courſe theſe are not perpendicular, but have the ſame inclination as the veins.

Levels driven from the ſhafts, are carried on in the ſubſtance of the lode, follow its direction, and are the principal means by which diſcoveries of ore are made and purſued.

The principal methods by which lodes are diſcovered are the two following: 1. By removing the ſoil covering the ſurface of the rock, by which the back of the vein is laid bare, and expoſed to view. This may happen accidentally, in the formation of roads, ditches, and ſo on; or, as is more uſual, it may be done for the expreſs purpoſe of diſcovery, in conſequence of indications of veins being near at hand, ſuch as detached fragments being found, or ſprings of water impregnated with metal being obſerved. This proceſs is conducted by ſinking trenches, or pits, deep enough to reach the ſurface of the rock, called by miners the *ſhelf;* which trenches are called *ſhoding pits*, or *coſteening pits*. The detached fragments, waſhed from the backs of lodes, are uſually called *ſhodes*, or *ſhode-ſtones*.

The ſecond mode of diſcovering veins is by levels, or horizontal cuts, driven under ground, which in their progreſs through the rock, or, as the miners ſay, acroſs *the country*, interſect and expoſe lodes before unknown. Such levels muſt have a direction acroſs the uſual courſe of the lodes, and are either conducted for the expreſs purpoſe of finding new veins, or for ſome other object; and then may occaſionally be the means of valuable reſults of this ſort.

Many rich mines have been opened, in conſequence of a diſcovery made by carrying on an adit, or by driving a croſs level from a ſhaft, or from one lode to another known to be parallel to it. The practice of driving adits for the purpoſe of diſcovery is more frequent than it uſed to be. The Taviſtock canal has a long tunnel driving through a hill, deſtined principally for this purpoſe, and which has already been attended with very great ſucceſs.

Lodes ſeldom contain ore near the ſurface of the ground: it is, therefore, an eſſential quality in a miner's judgment to decide on the indications preſented by them, and to determine the amount of riſk which their appearances will warrant on a further trial.

There are niceties in this buſineſs which cannot be deſcribed,

ſcribed, but muſt be ſeen and ſtudied to be underſtood, and with which ſkilful miners are converſant; but the moſt experienced is liable to have his predictions falſified by the fluctuating nature of theſe hidden receptacles of various matter.

The indications moſt depended on, in forming a judgment of the value of a lode, are derived from conſidering the following circumſtances:

1. The nature of the ſubſtances contained in the vein.
2. The kind of rock in which it is found.
3. The width and regularity of the vein, conſidering, at the ſame time, its direction and dip.
4. The ſtructure of the vein, ſuch as the being open and pervious to water, or, on the contrary, hard and cloſe.

Theſe ſymptoms may be, on the whole, conſidered as pertaining to veins containing all kinds of metals, though varying in ſome in a certain degree: thus a hard cloſe lode may be favourable for tin, though not ſo for copper or lead.

When a vein is found exhibiting all or moſt of the appearances which experience has determined to belong to thoſe which are productive, it is called a *kindly lode*, and is generally purſued with vigour, and at an expence proportioned to the prevalence and continuance of the favourable ſymptoms.

We ſhall endeavour to conſider the principal indications, according to the order above ſtated, and point out the leading facts to be obſerved in this important branch of a miner's buſineſs.

I. *Of the nature of the ſubſtances contained in the vein.*

Theſe ſubſtances vary according to the depth to which the lode is opened; thoſe near the ſurface being generally different from the contents of the vein deeper under ground.

The firſt thing for which a miner looks is what in Cornwall is called *goſſan*. This ſubſtance does not appear to have been very accurately deſcribed, but is apparently a decompoſed mineral of an iron-ochre colour, varying from yellow to brown-red and chocolate-brown. It is of a ſpongy, cellular texture, of little ſpecific gravity, and is generally ſoft and friable. It is probably the reſult of the decompoſition of pyrites or mundic, together with quartz, and contains a conſiderable portion of iron, and not unfrequently a mixture of tin and copper ores. When theſe latter are preſent in the combination, it is a moſt favourable ſymptom; but even without them, goſſan on the back of a lode warrants a trial to a certain extent. It can by no means be aſſerted, that the moſt promiſing goſſans have always been followed by ore, on a further purſuit; but perhaps there is hardly an inſtance of a lode rich in ore, which has not a bunch of *kindly goſſan* ſomewhere on the back.

The next ſubſtance, proceeding in depth, upon which reliance may be placed, is *mundic*, including in this name pyrites of all kinds, whether arſenical or ſulphuretted, containing iron or copper. Mundic is found at all depths and in all ſituations in veins: it frequently ſurrounds bunches of copper ore, and is therefore a favourable ſymptom, as they are approached; and indicates their decline, when paſſed through on the other ſide. It ſhould, however, be recollected, that mundic is very generally found, and therefore it muſt not be depended on by itſelf.

The earthy ſubſtances, which are eſteemed favourable to the exiſtence of valuable metallic ores, are principally quartz, going under the general name of ſpar; a kind of clay called *flookan*; and, what is not very abundant, *fluor*, diſtinguiſhed by the appellation of *candied ſpar*.

The firſt and the chief ingredient in veins, *quartz*, is kindly, when it is in a looſe friable form, often cryſtallized, and cementing detached fragments of killas and the other ſubſtances before enumerated. It is unpromiſing when in a cloſe amorphous form, and is then termed a *ſharp hungry ſpar*.

The *flookan*, or clay, generally forms a branch or vein on one of the walls of the lode, and ſeems to be the diviſion between that and the rock containing it.

The decompoſition of the adjoining ſtrata ſeems to have been the origin of this ſubſtance, which is called by ſome foreign writers the *ſaalbande*.

Beſides fluor, on which miners are not well agreed as to its promiſing aſpect, and which is not often found in quantity, are ſome other minerals, likewiſe of not very frequent occurrence, but eſteemed favourable; ſuch as *prian*, a kind of decompoſed quartz, and *peach* or chlorite.

Hitherto we have ſaid nothing of the judgment formed by ores found in a lode; it depends upon the following circumſtances:

1. The ſituation, whether ſhallow or deep.
2. The mode of depoſit, whether ſlightly ſprinkled through the lode, or forming ſhoots or bunches of large or ſmall extent.
3. The quality of the ore.

Under the firſt head, moſt miners agree that, as to copper lodes, rich bunches of ore found near the ſurface are not to be depended on as ſhewing that a mine will be very productive; it having often been found that ſuch depoſits have been followed by poverty at a greater depth. Tin and lead are found nearer the ſurface than copper. When a lode is ſpotted with ſmall quantities of ore, and the other ſubſtances are kindly, ſuch as the goſſan and ſpar, the appearance is promiſing; but when the lode is hard, and in other reſpects unkindly, then ſmall ſtrings of ore are not to be reckoned on as particularly favourable. After a certain depth, a regular branch, or, as it is called, a *leader* of ore of any width, occupying part of a good-ſized vein, and increaſing or even fluctuating in ſize as it is purſued, is on the whole the beſt ſymptom, particularly if connected with favourable accompanying ſubſtances.

Under the head of quality of the ore as an indication of future proſperity to a mine, it muſt be remarked that nothing requires to be received with greater caution than promiſes of ſucceſs ſuppoſed to be derived from the richneſs of individual ſpecimens. We are ſpeaking now more particularly of copper lodes. Few, we believe, of the moſt profitable mines produce much ore of the richer varieties, which indeed is ſeldom found to occupy veins of conſiderable width: on the contrary, moſt of the beſt mines are thoſe which yield ore in large quantities, but poorer in metallic content. This obſervation has been likewiſe made on the ſilver mines of South America, according to the account of Humboldt. Copper ores are found in a greater variety of ſpecies near the ſurface than they are in depth; and therefore the miner's experience only will ſerve to diſcriminate perfectly on this point: but we wiſh to put all who are concerned in mining on their guard againſt a fallacious hope, too frequently excited by the aſſay of a ſtone of ore, which in reality often predicts the very reverſe of what it is ſtated to do by the artful or ignorant.

II. The ſecond indication to be attended to, in eſtimating the proſpect of ſucceſs on a particular vein, has been ſtated to be *The kind of rock in which it is found.*

It is unneceſſary here to go into a voluminous account of rocks, becauſe the great mines of England, as well as of the world, being found in ſuch mountains as are conjectured to be of very early formation, do not admit the varieties in this reſpect, which ſome, who are acquainted only with other diſtricts, where probably a later formation has exhibited different phenomena, might conjecture.

Lead-mines, indeed, exiſt in many parts of England, in various rock, and under various circumſtances; but no general rules of mining can be formed from depoſits of a metal, which appears to have taken its place at a period comparatively late. Such rules can only be applicable to ſeparate diſtricts, where the circumſtances attending the depoſits are ſimilar.

There are two general claſſes of rock which claim the diſtinction of metalliferous above all others. Theſe are the *killas* of the Corniſh miner, or grauwacke or tranſition ſlate of Werner; and granitic rocks, including porphyry, gneiſs, and other varieties, known in Cornwall by the general name of *growan*.

Of theſe the great majority of mines are in killas, or grauwacke, not only in Cornwall and Devon, but in Scotland, in the Hartz, in the Saxon Erzgebirge, on the Rhine, in Bohemia, Sileſia, Moravia, Salzburg, and other diſtricts important for their mineral products.

Granitic rocks are not ſo metalliferous as the *killas*, but productive veins are found in them; and, as Dr. Berger has well obſerved in his account of Devon and Cornwall, in the firſt volume of the Tranſactions of the Geological Society, even the killas is not a depôt of metallic veins to any extent, but near its junction with the granite: and this obſervation had been made, as he ſays, by baron Born and Ferber on the mines of the continent.

This fact of moſt mines being in one prevailing rock, would ſeem to ſimplify the exerciſe of judgment in a miner ſpeculating on the effect of the rock upon the contents of a lode. But though killas is ſo univerſal, it is far from being all alike: on the contrary, it conſiſts of many varieties. Theſe varieties do not alternate according to certain rules, like the beds of ſecondary rocks; but exhibit changes in poſition and extent, more or leſs frequent, and moſt uncertain and capricious.

The varieties of killas, which are eſteemed the moſt kindly for copper, are the blue and the white, more eſpecially if of a tender, ſlaty texture. Tin often is found in abundance in harder killas, more irregular in its ſtructure, and of a darker colour, indicating the preſence of iron. Practice alone can enable men to judge of the ſhades of difference in theſe reſpects, which long experience has pointed out as eſſential to be attended to: and even then, allowance muſt be made for exceptions which frequently occur; rules which ſeem to hold good, when applied to one mine, being often inapplicable to another.

III. The third thing to be conſidered is *The width and regularity of the vein, and its direction and dip.*

Theſe are important circumſtances. If the lode be ſmall, it cannot be expected that abundant depoſits of metal can be found; and if it has not the characters belonging to a regular fiſſure, it is probable that the miner will ſoon be diſappointed, by finding it dwindle to a trifling branch, or ſplit into ſeveral inſignificant ramifications.

Every large and productive lode is accompanied by other veins running parallel to it, or nearly ſo, which often fall into the main lode, and generally enrich it by their junction.

Theſe muſt be carefully attended to, and ſought after, as the changes that they produce are often moſt important, and the quantity of ore which they yield is frequently very great. It has indeed been aſſerted, that there is hardly a mine working on a ſingle vein only, which has been profitable to any great degree.

The direction of the lode ſhould be carefully aſcertained; becauſe certain ores are only found in veins which have their courſe in common with others having ſimilar depoſits in the diſtrict.

Thus the writer of the preſent article has obſerved that copper and tin, in Cornwall, muſt only be expected in lodes running eaſt and weſt; while lead is raiſed from ſuch as have a direction at right angles to them, or from north to ſouth.

The more uſual dip or underlay, in copper mines particularly, is to the north; but ſome lodes that underlay to the ſouth have been very productive. In either caſe, it is no favourable ſymptom to find the inclination from the perpendicular to be great; and it may be ſaid to be ſo, if it exceed four feet in the fathom.

When a lode often ſplits or divides into two or more branches, it is ſubject to fluctuation in its produce; and theſe occurrences are important to be noticed with attention, as they afford prognoſtics as to the future ſucceſs of working.

IV. The fourth and laſt head, under which we have arranged the appearances of productive lodes, is that relating to *The ſtructure of the vein, whether open or porous, and thus pervious to water; or, on the other hand, denſe and cloſe, and conſequently dry.*

All miners agree in this, that water being found to be abundant in a lode is an omen of a very favourable nature; and it is often confidently aſſerted, that no large returns of ore have been made from dry veins. As far as the experience of the writer of this article goes, it ſerves to confirm the obſervation.

Water, indeed, may be found paſſing freely through croſs-courſes, and other veins, from which metallic depoſits are abſent; but then ſuch veins will be found to have all the characters which are adduced as proofs of a later formation, and are therefore eaſily diſtinguiſhed from metallic veins.

Large lodes act as natural underdrains, and are channels through which water percolates; ſo that the rock lying on either ſide may often be ſunk upon with but little interruption from water until the vein is cut into, and then abundant ſtreams flow out, and would put an end to further labour, if it were not for the aid of proper engines to get rid of it.

The quantity of water will of courſe be, in ſome degree, proportioned to the extent of the wide and porous parts of the lode; and, as it is from theſe parts only that much ore can be expected, the water forms in the firſt inſtance a pretty good prognoſtic.

If, in driving upon the courſe of a ſmall, cloſe, and unproductive lode, a ſtream of water be ſuddenly met with, it indicates the approach to an enlargement in the vein, and is a moſt favourable ſymptom; and it is, in point of fact, almoſt always obſerved before a good courſe of ore is ſeen.

The mines of Devon and Cornwall abound with water in a much greater degree than perhaps any others; and as evidence of this, we may adduce the number of vaſt ſteam-engines and overſhot water-wheels employed for the ſole purpoſe of draining them. We believe, likewiſe, that when the quantities of ores raiſed in this diſtrict be compared with thoſe of any other which yield them from *true veins*, they will be found abundant in the ſame proportion.

Under the head of the internal ſtructure of lodes may be noticed the cavities, called by the Germans *druſes*, and by the Corniſh miners *voogs*: theſe are obſerved moſt frequently in large veins, and in ſuch, of courſe, aſſiſt in the paſſage of water, and may be claſſed in the ſame place as a favourable indication. In theſe voogs are found all the varieties of cryſtals; and thus the preſence of theſe in a lode is likewiſe conſidered promiſing, more particularly where obſervations are made on a vein at no great depth: for as the mine becomes deeper the lode often becomes more compact, and the miner calculates upon finding *ſolid courſes of ore*.

In connection with this part of the ſubject, the *walls* which encloſe the vein are not to be diſregarded, when the lode itſelf is conſidered, as they ſhould be found to be well determined, ſmooth, and regular. The rock of which they are formed ſhould be of the hard ſchiſt called by miners *capel*; and if penetrated with traces of ore, it may be conſidered as a ſymptom of large depoſits. On each ſide of the walls, which uſually differ ſomewhat from the adjoining rock, as if altered by the preſence of the vein, the ſtrata may generally be obſerved to be twiſted or bent downwards, in a ſlight degree towards the lode, which is in general conſidered to be more the caſe near large veins than near thoſe which are ſmaller.

Having now detailed the principal characteriſtics of lodes, as important to the practical miner, deſcribed the modes of diſcovering them, and the ſymptoms by which a judgment is formed of their contents, as far as relates to working them for the metals; we leave the conſideration of them, in a geological point of view, for the article VEIN. The operations of working upon them will be deſcribed under the head of MINING, and under that of ORE.

LODE, in *Rural Economy*, a provincial term applied to ſignify ford, in ſome diſtricts.

LODER, in *Geography*, a town of Bavaria; 25 miles S. of Augſburg.

LODESAN, a country of Italy, in the Milaneſe, bounded north and weſt by the duchy of Milan, eaſt by the Cremaſco and the Cremones, ſouth by the Piacentin and Paveſe; and now forming the department of the Adda. It is populous and fertile, though ſmall; and particularly celebrated for its cheeſe, of which, it is ſaid, the inhabitants annually export to the amount of 70,000*l.*; the number of cows kept here being reckoned at 30,000. The capital is Lodi.

LODESE', or GAMLA *Lodeſe*, a town of Sweden, in Weſt Gothland, which ſuffered ſo much from fire in the thirteenth and fourteenth centuries, that the inhabitants removed to New Lodeſe, or Nydoleſe.

LODESMAN, or LOCMAN, a pilot eſtabliſhed for conducting veſſels in and out of harbours, or up and down navigable rivers. See PILOT.

LODE'VE, in *Geography*, a town of France, and principal place of a diſtrict, in the department of Hérault, and, before the revolution, the ſee of a biſhop; 24 miles W. of Montpellier. The place contains 7843, and the canton 13,959 inhabitants, on a territory of 307½ kiliometres, in 10 communes. N. lat. 43° 44'. E. long. 3° 24'.

LODGMENT, in *Military Affairs*, ſometimes denotes an encampment made by an army.

LODGMENT is more frequently uſed for a work caſt up by the beſiegers, during their approaches, in ſome dangerous poſt, which they have gained, and where it is abſolutely neceſſary to ſecure themſelves againſt the enemy's fire; as in a covert-way, in a breach, the bottom of a moat, or any other part gained from the beſieged.

Lodgments are made by caſting up earth, or by gabions, or paliſades, woolpacks, faſcines, mantelets, or any thing capable of covering ſoldiers in the place they have gained, and are determined to keep.

LODI, LA, in *Biography*, a young female ſinger, in the ſervice of the elector of Bavaria, at Munich in 1772, and now, if ſhe lives, an old one; ſo that a few remarks upon her ſlight imperfections can do her neither good nor harm, but may probably ſtimulate a wiſh of purification of voice in others. We thought that, in general, the tone of the Lodi's voice was clear and brilliant, and her manner of ſinging and acting elegant and graceful; yet thought, if there was any little defect in her voice, it was occaſioned by a ſlight obſtruction in the throat, particularly in ſuſtaining low notes. Theſe were our thoughts the firſt time we heard her. The ſecond time, we were more pleaſed with her performance than the firſt; yet ſtill imagined that her voice wanted a little more room in its paſſage. The third time we heard her in her beſt character, in the performance of which ſhe ſtill gave us more pleaſure; but yet we could not get rid of our former remarks on the conduct of her voice in ſuſtaining certain low and long notes.

Theſe remarks, made on the Lodi 52 years ago, might, with reſpect to voice, be fairly applied to Mrs. Hindmarſh in 1804.

LODI, in *Geography*, a city of Italy, formerly the chief town of Lodeſan, now the capital of the department of Adda, built by the emperor Frederick Barbaroſſa, on an eminence, in a plain watered by the river Adda. It is the ſee of a biſhop, and contains, beſides the cathedral, two collegiate and ſeven pariſh churches, and 26 convents. This is a place of little trade, its chief commodities being cheeſe (ſee LODESAN) and a beautiful kind of earthen ware reſembling china. It is well built, and ſurrounded with walls, about three miles from the ancient town of the ſame name, called alſo "Laus Pompeii." The number of inhabitants is eſtimated at about 12,000. On the 11th of May 1796, the town was taken by the troops of the French republic, under the command of Bonaparte, Maſſena, and Angereau; after the paſſage of the bridge had been conteſted by 10,000 Auſtrians, and 30 pieces of artillery. The Auſtrians loſt in killed, wounded, and priſoners, between two and three thouſand men; 18 miles S.E. of Milan. N. lat. 45° 21'. E. long. 9° 30'.

LODOMIRIA, a territory of Poland, which, together with *Galicia* (which ſee), was ceded to the houſe of Auſtria in the late partition of Poland, A.D. 1772, and is now incorporated under this appellation with the Auſtrian dominions. The number of inhabitants in this ceded country amounted, in 1776, to 2,580,796. Hoeck computes Eaſtern Galicia and Lodomiria at 2,797,119, and Weſtern Galicia at 1,106,178, The mountainous parts of Galicia and Lodomiria afford fine paſtures; the plains are moſtly ſandy, but abound in foreſts, and are fertile in corn. The principal articles of traffic are cattle, hides, wax, and honey; and theſe countries contain mines of copper, lead, iron, and ſalt.

LODRONE, a town of Italy, in the Trentin, on the borders of the Breſſan, near a ſmall lake, called the "lake of Idro;" 25 miles S.W. of Trent.

LODOSA, a town of Spain, in Navarre, on the Ebro; 17 miles E. of Eſtella.

LODYPOUR, a town of Hindooſtan, in Bahar; 18 miles S. of Patna.

LODZIEZE, a town of Lithuania, in the palatinate of Troki; 48 miles N.N.W. of Grodno.

LOE, a town of Norway; 48 miles N.E. of Drontheim.

LOE, in *Rural Economy*, a term uſed to ſignify a little round hill, or a heap of ſtones.

LOEBEGUN, or LOBOCHIN, a town of the duchy of Magdeburg; 44 miles S. of Magdeburg.

LOEBOE, or LOEHOE, a kingdom of Celebes, which was the moſt powerful and extenſive of all the ſtates of this iſland, before thoſe of Macaſſar and Boni attained their ſubſequent celebrity. It ſtretches at preſent from Palopa, the capital of the country, to Larompo, having an extent of about 20 leagues along the weſtern ſhore of the bay of Boni, and from the other ſide of the city, over the whole of the S.E. part of Celebes, between Bugueſs-bay and the E. coaſt of the iſland, as far as the Alforeſe will ſuffer them inland; to the W. it is bounded by Wadjo, and to the N. by Taradja. The land is fertile in paddee; it yields likewiſe good iron, and much gold is found in the rivers. The firſt king mentioned in the records of the Dutch company, and called "Crain Haroo," was ſubdued by the arms of the company, at the ſame time with the Macaſſars at Bouton. For an account of its diſſolute queen, ſee TANETE.

LOEFLINGIA, in *Botany*, named by Linnæus in honour of his friend and favourite pupil Peter Loefling, a Swede, who was born in the year 1729, in the province of Gäſtrikeland. He began to ſtudy medicine at the age of 16, and from his proficiency in the ſcience of Natural Hiſtory he afterwards obtained, through the recommendation of Linnæus, the appointment of botaniſt to the king of Spain, in which capacity he explored the botanical treaſures of South America, where he died Feb. 22, 1756. His name frequently occurs in the writings of his preceptor, who publiſhed at Stockholm, in 1758, a collection of Loefling's letters, and the Latin deſcriptions of Spaniſh and American plants which he left behind him, with a biographical preface of his own, in Swediſh. A German tranſlation of this volume, by Kölpin, appeared at Berlin in 1766. The inaugural diſſertation of Loefling on "the buds of trees" is printed in the *Amoenitates Academicæ*, v. 2. 182.—Linn. Gen. 24. Schreb. 33. Willd. Sp. Pl. v. 1. 191. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 79. Juſſ. 299. Lamarck Illuſtr. t. 29. Gærtn. t. 129.—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Caryophyllei*, Linn. *Caryophylleæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five, erect, lanceolate leaves, marked on each ſide at the baſe with a ſmall tooth, ſharp-pointed, permanent. *Cor.* Petals five, very ſmall, oblong-ovate, cloſed together in the form of a globe. *Stam.* Filaments three, the length of the corolla; anthers roundiſh, twin. *Piſt.* Germen ſuperior, ovate, triangular; ſtyle thread-ſhaped, a little dilated upwards; ſtigma rather obtuſe. *Peric.* Capſule ovate, nearly triangular, of one cell and three valves. *Seeds* numerous, ovate-oblong.

Eſſ. Ch. Calyx of five leaves. Corolla of five petals, very ſmall. Capſule of one cell, and three valves.

1. L. *hiſpanicum.* Spaniſh Loeflingia. Linn. Sp. Pl. 50. Loefl. It. 113. t. 1. f. 2. Cavan. Ic. v. 1. 64. t. 94.—Leaves awl-ſhaped, ſharp-pointed. Flowers axillary, ſeſſile.—Found on open hills in the neighbourhood of Madrid, and other parts of Spain, flowering in June.—*Root* annual, zig-zag, ſmooth. *Stems* procumbent, ſometimes a little aſcending, jointed, round, ſlightly pubeſcent, viſcid, about two inches long. *Leaves* in pairs at the joints of the ſtems, ſometimes three or four together. *Flowers* nearly white. Linnæus remarks, that this ſpecies approaches in habit to *Scleranthus* or *Hernieria*.

2. L. *indica.* Indian Loeflingia. Willd. n. 2. Retz. Obſ. faſc. 4. 8. (Pharnaceum depreſſum; Linn. Mant. 562.)—Leaves oblong. Flowers axillary, cymoſe.—A native of rice fields and dried pools in the Eaſt Indies, where it abounds, according to König, in April and May.—*Root* very long and branching. *Stems* numerous, proſtrate, about a ſpan in length, pubeſcent. *Leaves* two, four or more together at the joints, almoſt ſeſſile. *Stipulas* ſolitary, ſmall, membranaceous. *Flowers* nearly ſeſſile, cinereous, with a trifid ſtyle. Linnæus, who places this ſpecies in *Pharnaceum*, ſays that it reſembles a *Mollugo*, and that it puts forth its flowers only in fine weather.—Retzius and Willdenow properly make it a *Loeflingia*, of which authors, the former obſerves, that *L. indica* has dark-green and keeled calyx-leaves with a broad ſcaly margin. The *corolla* is purple, ſmaller than the *calyx*. The *capſule* of one cell, with many ſeeds.

LOEILLET, JOHN, in *Biography*, a relation of John Baptiſt Loeillet of Ghent, the famous maſter on the common flute, and voluminous compoſer for that inſtrument. John the younger was a celebrated harpſichord maſter, and performer in the opera band in London, while Corbet was the leader.

Having a large room in the houſe which he occupied in Hart-ſtreet, Covent Garden, he eſtabliſhed a weekly concert there, which was frequented chiefly by gentlemen performers, who rewarded him liberally for conducting it. Corelli's concertos were firſt performed in England at this concert, where Mr. Needler, at the head of dilettanti players on the violin, was the leader.

Loeillet was not only an excellent teacher of the harpſichord, but a good compoſer for that inſtrument, and a minuet in his leſſons, in the key of A minor, which was in great favour with the ladies of that time, from the vulgar pronunciation of Loeillet's name, was long ſuppoſed to have been compoſed by John Baptiſt Lully, whoſe name was prefixed to it in many printed books, nor was the miſtake ever publicly cleared up.

Loeillet died about the year 1728, after accumulating, by induſtry and economy, a fortune of 16,000*l.* The works which he publiſhed, though numerous, are now only to be traced in Walſh's old catalogues.

LOENEN, in *Geography*, a town of Holland; 10 miles S.W. of Naerden.

LOESDRECHT, a town of Holland; eight miles S. of Naerden.

LOESELIA, in *Botany*, received its name from Linnæus, in honour of John Loeſel, Profeſſor of Medicine at Königſberg in Pruſſia, who was born in the year 1607, and died in 1655. By the direction of our author's will, his ſon edited a catalogue of the native plants of Pruſſia, which is by no means a deſpicable work. It abounds with ſeveral curious notes, and contains many rare plants which till then were unknown as natives of Pruſſia. He had alſo prepared ſeveral excellent plates, and theſe, together with his manuſcripts, partly by the wiſh of his ſon to perpetuate his father's fame, and partly by royal authority, were afterwards committed to the charge of his ſucceſſor, Profeſſor John Gottſched, who compiled from them the *Flora Pruſſica, ſeu Plantæ in Regno Pruſſiæ ſponte naſcentes*, which was publiſhed in quarto in 1703. The book is ſcarce, but is frequently cited for the plates.—Linn. Gen. 317. Royen. L. Bat. 299. Schreb. 415. Willd. Sp. Pl. v. 3. 323. Mart. Mill. Dict. v. 3. Juſſ. 135. Lamarck Illuſtr. t. 527. Gærtn. t. 62. (Royenia; Houſt. MSS.)—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Convolvuli*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, four-cleft, acute, ſhort, permanent. *Cor.* of one petal, unequal; tube the length of the calyx; limb in five, ovate-lanceolate, equal ſegments, all deflexed towards the lower ſide. *Stam.* Filaments four, the length of the corolla, two of them ſhorter, all oppoſite to the ſegments of the petal and reflexed, in a contrary direction to the corolla; anthers ſimple. *Piſt.* Germen ſuperior, ovate; ſtyle ſimple, placed like the ſtamens; ſtigma thickiſh. *Peric.* Capſule ovate, of three cells. *Seeds* ſolitary or two together, ſlightly angulated.

Obſ. Gærtner remarks, that he found five ſtamens in all the flowers of this genus which he had examined, though one of them was conſtantly ſhorter than the reſt. Hence it has been ſuggeſted that *Loeſelia* ſhould be referred to *Pentandria*.

Eſſ. Ch. Calyx four-cleft. Corolla with its ſegments all leaning one way. Stamens oppoſite to the petal. Capſule of three cells.

1. L. *ciliata*. Fringed Loeſelia. Linn. Sp. Pl. 875. Gærtn. t. 62. f. 3.—Found by Dr. Houſtoun at Vera Cruz in South America.—*Stem* erect, ſlightly quadrangular. *Leaves* oppoſite, lanceolate-ovate, ſharply ſerrated. *Flowers* yellow, forming a head at the ends of the branches, accompanied by imbricated, ovate, fringed *bracteas*.

This genus is fully deſcribed by Gærtner, who moſt probably muſt have made his deſcription from the ſpecimen ſent by Dr. Houſtoun to Mr. Miller's collection, now in the poſſeſſion of the right honourable ſir Joſeph Banks. Linnæus had it not in his own herbarium, but appears to have ſeen it in the hands of Adrian Van Royen during his ſtay at Leyden. Hence it found admiſſion into the appendix of the firſt edition of his *Genera Plantarum*, p. 348.

LOEVESTEIN, or Louvestein, in *Geography*, a fortreſs of Holland, where Grotius was confined, and whence he was delivered by a ſtratagem of his wife. See the article Grotius.

LOEVI, in *Ancient Geography*, a people of Italy, whoſe cantonment lay between the rivers Seſſilis and Ticinus, now the Seſia and Teſino.

LOFANGER, in *Geography*, a town of Sweden, in Weſt Bothnia; 40 miles N.N.E. of Umea.

LOFANGO, one of the ſmaller Friendly iſlands; five miles E.S.E. of Neeneeva.

LOFEEREN, a cluſter of ſmall iſlands in the North ſea, near the coaſt of Norway. N. lat. 68°.

LOFFALO, a ſmall iſland in the gulf of Finland. N. lat. 60° 2′. E. long. 46° 3′.

LOFFINGEN, a town of Germany, in the lordſhip of Furſtenberg, having a medicinal bath; ſix miles W. of Furſtenberg.

LOFFODEN Islands, a cluſter of iſlands off the Norwegian coaſt, in N. lat. 67° to 68°. Theſe iſlands are numerous and extenſive, and noted for the whirlpool of Malcſtrom. They have excellent fiſheries, and the paſturage ſuffices for a great number of ſheep.

LOFSTA, a town of Sweden, in Smaland; 70 miles N. of Calmar.—Alſo, a town of Sweden, in the province of Upland, in which are a hammer-mill, eight forges, and a ſmelting furnace; 40 miles N. of Upſal.

LOFTUS Heights, the barrier-port in the S.W. corner of the United States, on the E. ſide of the Miſſiſippi, in Adams county, Miſſiſippi territory, about 40 miles below Natchez. The plan of the works here conſtructed preſents the handſomeſt military object in the United States.

LOFVESTA, a ſea-port town of Sweden, in the province of Schonen; 25 miles S. of Chriſtianſtadt.

LOG, in the *Jewiſh Antiquities*, a meaſure which held a quarter of a cab, and conſequently five-ſixths of a pint. There is mention of a log, 2 Kings, vi. 25. under the name of a *fourth part of a cab*. But in Leviticus the word log is often met with, and ſignifies that meaſure of oil, which lepers were to offer at the temple after they were cured of any diſeaſe.

Dr. Arbuthnot ſays, that the log was a meaſure of liquids, the ſeventy-ſecond part of the bath or ephah, and twelfth part of the hin, according to all the accounts of the Jewiſh writers.

Log, a ſea-term, ſignifying a ſmall piece of timber of a triangular, ſectoral, or quadrantal figure, on board a ſhip, generally about a quarter of an inch thick, and five or ſix inches from the angular point to the circumference. It is balanced by a thin plate of lead, nailed upon the arch, or circular ſide, ſo as to ſwim perpendicularly in the water, with about two-thirds immerſed under the ſurface.

Log-*line*, a little cord, or line, about a hundred and fifty fathoms long, faſtened to the log, by means of two legs, one of which paſſes through a hole at the corner, and is knotted on the oppoſite ſide, while the other leg is attached to the arch by a pin fixed into another hole, ſo as to draw out occaſionally. By theſe legs the log is hung in equilibrio; and the line thus annexed to it is wound round a reel fixed for that purpoſe in the gallery of the ſhip.

This line, from the diſtance of about ten, twelve, or fifteen fathoms off the log, has certain knots or diviſions, which ought to be at leaſt fifty feet from each other; though it was the common practice at ſea, not to have them above forty-two feet aſunder.

The length of each knot ought to be the ſame part of a ſea-mile as half a minute is of an hour; and admitting the meaſurement of Mr. Norwood, who makes a degree on a great circle of the earth to contain 367,200 Engliſh feet, or about 69½ Engliſh ſtatute miles; and, therefore, $\frac{1}{60}$ of it, or a nautical mile, will be 6120 feet; $\frac{1}{120}$th of 6120, or 51 feet, ſhould be the length of each knot. But becauſe it is ſafer to have the reckoning rather before the ſhip than after it, therefore fifty feet may be taken as the proper length of each knot. The knots are ſometimes made to conſiſt only of forty-two feet each, even in the preſent practice; and this method of dividing the log-line was founded on the ſuppoſition that ſixty miles, each of 5000 Engliſh feet, made a degree; for $\frac{1}{120}$th of 5000 is 41⅔, or, in round numbers, 42 feet. Mariners, rather than quit the old way, though known to be erroneous, uſe glaſſes for half minute ones, that run but 24 or 25 ſeconds. They have alſo uſed a line of 45 feet to 30 ſeconds, or a glaſs of 28 ſeconds to 42 feet. When this is the caſe, the diſtance between the knots ſhould be corrected by the following proportion: as 30 is to 50, ſo is the number of ſeconds of the glaſs to the diſtance between the knots upon the line. The heat or moiſture of the weather has often a conſiderable effect upon the glaſs, ſo as to make it run ſlower or faſter; it ſhould, therefore, be frequently tried by the pendulum in the following manner. On a round nail hang a ſtring that has a muſket-ball fixed to one end, carefully meaſuring between the centre of the ball and the ſtring's loop over the peg 39⅛ inches, being the length of a ſecond pendulum; then ſwing it, and count one for every time it paſſes under the peg, beginning at the ſecond time it paſſes, and the number of ſwings made during the time the glaſs is running out, ſhews the ſeconds it contains. The line alſo is liable to relax and ſhrink, and ſhould, therefore, be occaſionally meaſured.

The uſe of the log and line is, to keep account, and make an eſtimate of the ſhip's way, or diſtance run; which is done by obſerving the length of line unwound in half a minute's time, told by a half-minute glaſs; for ſo many knots as run out in that time, ſo many miles the ſhip ſails in an hour. Thus, if there be four knots veered out in half a minute, the ſhip is computed to run four miles an hour.

The author of this device for meaſuring the ſhip's way is not known; and no mention of it occurs till the year 1607, in an Eaſt India voyage, publiſhed by Purchas: but from that time its name occurs in other voyages among his collections: and henceforward it became famous, being taken notice of both by our own authors, and by foreigners; as by Gunter in 1623; Snellius, in 1624; Metius, in 1631; Oughtred, in 1633; Herigone, in 1634; Saltonſtall, in 1636; Norwood, in 1637; Fournier, in 1643; and almoſt by all the ſucceeding writers on navigation of every country. See *Marine* SURVEYOR.

LOG, *to heave the,* as they call it, they throw it into the water, on the lee-ſide, letting it run, till it comes without the eddy of the ſhip's wake; then one, holding a half-minute glaſs, turns it up juſt as the firſt knot, or the mark from which the knots begin to be reckoned, turns off the reel, or paſſes over the ſtern. As ſoon as the glaſs is out, the reel is ſtopped, and the knots run off are told, and their parts eſtimated.

It is uſual to heave the log once every hour in ſhips of war and Eaſt Indiamen; and in all other veſſels, once in two hours; and if at any time of the watch the wind has increaſed or abated at the intervals, ſo as to affect the ſhip's velocity, the officer generally makes a ſuitable allowance for it at the cloſe of the watch.

The log is a very precarious way of computing, and muſt always be corrected by experience and good ſenſe; there being a great deal of uncertainty in the yawing of the ſhip going with the wind aft, or upon the quarter, in the heaving of it, by its coming home, or being drawn after the ſhip, on account of the friction of the reel, and lightneſs of the log, in the courſe of the current, and in the ſtrength of the wind, which ſeldom keeps the ſame tenor for two hours together; which is the interval between the times of uſing the log, in ſhort voyages, though in longer ones they heave it every hour. Yet is this a much more exact way of computing than any other in uſe; much preferable certainly to that of the Spaniards and Portugueſe, who gueſſed at the ſhip's way, by the running of the froth or water by the ſhip's ſide; or to that of the Dutch, who uſed to heave a chip overboard, and to number the paces they walk on the deck, while the chip ſwims between any two marks, or bulk-heads on the ſide.

The above-mentioned errors, and particularly the log's being ſubject to drive with the motion which the water may have at its ſurface, whereas the experiment requires it to be fixed in the place where it is when the mark commencing the knots goes off the reel, have been conſidered by writers, and many methods have been propoſed to remove, or at leaſt to leſſen them. The late M. Bouguer propoſed a method, which has been thought deſerving of particular attention, in the Mem. Acad. Sc. 1747; afterwards in his Treatiſe on Navigation, publiſhed at Paris in 1753, and ſince reprinted in 1760, by the Abbé de la Caille. For this purpoſe, take for the log a conical piece of wood, which fix to the log-line paſſed through or along its axis, at about forty, fifty, or ſixty, or more feet, from one end; and to this end fix the diver, which is a body formed of two equal ſquare pieces of tin, or of thin iron plate, fixed at right angles to one another along their diagonals; and its ſize ſo fitted to that of the cone, that the whole may float. A cone of three inches diameter in the baſe, and of ſix inches in the ſlant height, is propoſed by M. Bouguer to ſuit a diver made of plates about 9$\frac{3}{4}$ inches ſquare; the interſection of the diagonals is joined to the log-line, and the loop and peg fixed as in the common log. However, it has been found, that no kind of wood uſed in Britiſh dock-yards, when formed into a cone of the above dimenſions, will float a diver made of ſtout tin plates, one ſide of the ſquare being 9$\frac{3}{4}$ inches. Such a diver weighing 1$\frac{1}{3}$ lb. avoirdupoiſe, required to float it, a cone of five inches diameter, and twelve inches on the ſlant ſide, ſo as the point of the cone, which was made of light fir, ſhould juſt appear above the water. Now ſuppoſing one ſide of ſuch a ſquare tin diver to be about ten inches, and made of plates only two-thirds of the thickneſs of the former, ſuch a diver would weigh, with its ſolder, about twenty ounces, and can be floated by a light fir cone of four inches diameter in the baſe, and ten inches in the ſlant height or length; and ſuch a compound log might, perhaps, be found on trial to be affected by about as much again as that propoſed by M. Bouguer, and conſequently the difference between the numbers given by the common log and compound log, muſt be augmented by two-thirds of itſelf, for the neceſſary correction, as below. When the compound log of Bouguer, above deſcribed, is hove overboard, the diver will ſink too deep to be much affected by the current or motion of the water at the ſurface; and the log will thereby keep more ſteadily in the place where it firſt fell; and conſequently, the knots run off the reel will ſhew more accurately the ſhip's rate of ſailing. As the common log is affected by the whole motion of the current, ſo this compound log will feel only a part thereof, *viz.* ſuch a part nearly as the reſiſtance of the cone is of the reſiſtance of the diver: then the reſiſtances of the above cone and diver are about as 1 to 5; and conſequently this log will drive but one-fifth part of what the common log would do; and ſo the ſhip's true run will be affected by one-fifth part only of the motion of the waters. To obtain the true rate of ſailing, it will be proper to heave alternately hour and hour, the common log, and this compound log; then the difference of their knots run off, augmented by its one-fourth part, is the correction; which applied to the knots of the common log, will give the ſhip's true rate of ſailing, at the middle time between the hours when theſe logs were hove. The correction is additive, when the compound log's run is the greateſt, otherwiſe it is ſubtractive. To find the courſe made good: increaſe the obſerved angle between the log-lines by one-fourth part; and this gives the correction to be applied to the apparent courſe, or the oppoſite of that ſhewn by the common log; the correction is to be applied to the $\left\{\begin{matrix}\text{right}\\ \text{left}\end{matrix}\right\}$ of the apparent courſe, when the bearing of the common log is to the $\left\{\begin{matrix}\text{left}\\ \text{right}\end{matrix}\right\}$ of the compound log. Or thus: the lengths run off both logs, together with their bearings, being known; in a card or compaſs apply the knots run off, taken from a ſcale of equal parts along their reſpective bearings, from the centre; join the ends, and in this line produced, on the ſide next the compound log's length, take one-fourth of the interval; then a line drawn from the end, thus produced, to the centre of the card, will ſhew the true courſe and diſtance made good. When a current, ſuch as a tide, runs to any depth, the velocity of that current may be much better aſcertained by the compound log than by the common one, provided the diver does not deſcend lower than the run of the current; for as thoſe ſhips which are deepeſt immerged, drive faſteſt with the tide; ſo the diver, by being acted on below, as well as the log on the ſurface, their joint motion will give the total effect to the current's motion better than what could be derived from the motion at the ſurface only. Alſo by ſuch a compound log, the depth to which any current runs, may be eaſily tried. Robertſon's Nav. book ix. § 1.

We have an account in the Voyage to the North Pole, p. 97, of two other logs, which were tried by captain Phipps: one invented by Mr. Ruſſel, the other by Foxon; both conſtructed upon this principle, that a ſpiral, in proceeding its own length in the direction of its axis through a reſiſting medium, makes one revolution round the axis; if, therefore, the revolutions of the ſpiral are regiſtered, the number of times it has gone its own length through the water will be known. In both theſe the motion of the ſpiral in the water is communicated to the clock-work withinboard, by means of a ſmall line, faſtened at one end of the ſpiral, which tows it after the ſhip, and at the other to a ſpindle, which ſets the clock-work in motion. That invented by Mr. Ruſſel has a half ſpiral of two threads, made of copper, and a ſmall dial with clock-work, to regiſter the number of turns of the ſpiral. The other log has a whole ſpiral of wood with one thread, and a larger piece of clock-work, with three dials, two of them to mark the diſtance, and the other divided into knots and fathoms, to ſhew the rate by the half-minute glaſs for the convenience of comparing it with the log. This kind of log will have the advantage of every other in ſmooth water and moderate weather; and it will be uſeful in finding the trim of the ſhip when alone, in ſurveying a coaſt in a ſingle ſhip, or in meaſuring diſtances in a boat between headlands and ſhoals; but it is ſubject to other inconveniences, which will not render it a proper ſubſtitute for the common log. See Phil. Tranſ. vol. xlviii. p. 532.

Log-*board* is a table divided into four or five columns, whereon are marked the reckonings of every day; from whence they are entered into the log-book or traverſe-book, whence it may be tranſcribed into the journals, and how much the ſhip gains in her courſe be eſtimated daily. In the firſt column of the log-board, is entered the hour of the day, from the noon of one day to the noon of the next; in the ſecond and third, the number of knots and fathoms the ſhip is found to run per hour, ſet againſt the hours when the log was hove: in the fourth, the courſes which the ſhip ſteers: and in the fifth, or right-hand column, the winds, the alterations of the ſails, the buſineſs doing aboard, obſervations made of the weather, variations of the compaſs, &c. See Journal.

Log-*book*, at ſea, a book ruled and columned like the log-board. It is uſed by ſome to enter the log-board's account in every day at noon, with the obſervations then made; and from hence it is corrected and entered into the journals. (See Journal.) The intermediate diviſions or watches of the log-book, containing four hours each, are uſually ſigned by the commanding officer in ſhips of war, or Eaſt Indiamen.

LOGAN, in *Geography*, a county of America, in the ſtate of Kentucky, containing 4870 inhabitants, beſides 730 ſlaves.

LOGANIA, in *Botany*, ſo denominated by Mr. R. Brown, after Mr. James Logan, Preſident of the Council, and Chief Juſtice of the Province of Pennſylvania, author of a ſmall Latin tract in ſupport of the Linnæan doctrine of the generation of plants, publiſhed at Leyden, in 1739, and republiſhed, we believe by Dr. Fothergill, at London, in 1747, with an Engliſh tranſlation. Brown Prodr. Nov. Holl. v. 1. 454. (Euoſma; Andr. Repoſ. v. 8. 520.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Gentianæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in five deep equal ſegments, permanent. *Cor.* of one petal, ſomewhat bell-ſhaped, rather hairy in the throat; limb in five deep, equal, roundiſh ſegments. *Stam.* Filaments five, equal, inſerted into ſome part of the tube, ſhorter than the limb; anthers ſmall, roundiſh. *Piſt.* Germen ſuperior, ovate, with a groove at each ſide; ſtyle ſhort, thick, permanent; ſtigma capitate, ſomewhat club-ſhaped. *Peric.* Capſule ovate, with a furrow at each ſide, ſeparating into two parts, each of one cell and two valves, with a longitudinal triangular receptacle to each cell. *Seeds* numerous, roundiſh, peltate, rough.

Eſſ. Ch. Calyx in five deep ſegments. Corolla ſomewhat bell-ſhaped, five-cleft, hairy in the throat. Stamens ſhorter than the limb. Stigma capitate. Capſule ſuperior, with two furrows, four valves, two cells, and a receptacle to each. Seeds peltate.

This New-Holland genus conſiſts of either ſhrubs or herbs, with oppoſite entire leaves, generally attended by ſtipulas, which are either united into a ſmall intrafoliaceous ſheath, or diſtinct; in the latter caſe, within the inſertion of the leaves or at their ſides; ſometimes there are no ſtipulas. Flowers either terminal or axillary, oppoſite in corymbs or cluſters, ſometimes ſolitary. Corolla white, ſometimes veined. Albumen fleſhy. Mr. Brown indicates its near affinity to *Genioſtoma*, ſee that article, and thence to the order of *Apocineæ*, and to *Uſteria*, one of the *Rubiaceæ*. He defines eleven ſpecies, eight of which are ſhrubs, with an obtuſe calyx, and the ſtamens within the tube; the reſt are herbaceous, or but ſlightly ſhrubby, with an acute calyx, and ſomewhat prominent ſtamens. Of the eight firſt-mentioned ſpecies, five have the ſtipulas united into a ſheath or ring within the inſertion of the leaves. Theſe are called true *Loganiæ*. A ſpecimen of them is

L. *latifolia*. Brown n. 2. (Exacum vaginale; Labill. Nov. Holl. v. 1. 37. t. 51.)—Leaves obovate, rather pointed at each end. Flowers corymboſe. Young branches ſmooth. Stem erect.—Native of the ſouthern part of New Holland. The *ſtem* is ſhrubby, about a yard high, with upright, ſquare, ſmooth, leafy branches. *Leaves* oppoſite, ſcarcely ſtalked, coriaceous, broadly obovate, above two inches long, entire, acute, tapering at the baſe, and united by means of the ſhort, tubular, intrafoliaceous *ſtipula*. *Flowers* numerous, in terminal and axillary, ſmooth, repeatedly three-forked, corymboſe *panicles*, with a pair of acute *bracteas* at each ſubdiviſion. It is remarkable that Labillardiere ſays nothing of their colour, neither does he here, or perhaps in any part of his work, ſeem to have made any notes on the ſpot, but merely to have deſcribed the dried ſpecimens after his return.

The three others have either ſetaceous, lateral, diſtinct ſtipulas, or none at all. Theſe anſwer to the genus *Euoſma* of Andrews.

L. *floribunda*. Brown n. 6. (Euoſma albiflora; Andr. Repoſ. t. 520.)—Leaves lanceolate, tapering at each end, ſmooth. Stipulas lateral, briſtle-ſhaped. Cluſters axillary, compound, ſhorter than the leaves; with downy flower-ſtalks.—Sent originally by Dr. White, from Port Jackſon. Mr. Andrews had it in flower from the fine collection of the Marquis of Blandford, at White Knights, where it was trained againſt a ſouth wall in the open air, and in April was covered with a profuſion of white bloſſoms, which had the ſcent of hawthorn. The *ſtem* of this plant was about four feet high, ſhrubby. *Branches* wand-like, oppoſite, ſquare, ſmooth, leafy, reddiſh. *Leaves* willow-like, tapering much at each end, near two inches long; ſmooth, ſhining and dark green above; whitiſh, opaque and obſcurely dotted beneath. *Cluſters* compound, axillary, ſhorter than the leaves. *Flowers* ſomewhat like lily of the valley, but only half as large. *Capſules* rugoſe.

The three laſt ſpecies of this genus, which have, as before mentioned, an acute calyx, and ſtamens inſerted into the throat of the corolla, have received from Mr. Brown a ſort of proviſional generic name, *Stomandra*, expreſſive of this laſt character; ſo that if any perſon chooſes to ſeparate them from *Logania*, he may not be at a loſs what to call them. Theſe are

L. *ſerpyllifolia.* Br. n. 9.—"Somewhat ſhrubby. Leaves ovate. Stipulas within the footſtalks, fringed like the calyx. Flowers terminal, ſomewhat corymboſe."—Gathered by Mr. Brown in the ſouth part of New Holland.

L. *puſilla.* Br. n. 10.—"Herbaceous. Leaves elliptical. Stipulas triangular, within the footſtalks. Flowers axillary, ſolitary."—Native of Port Jackſon.

L. *campanulata.* Br. n. 11.—"Herbaceous. Leaves linear, without ſtipulas. Flowers terminal. Flower-ſtalks and calyx downy."—From the ſouth part of New Holland.

LOGARITHMIC, Atmospherical, is a curve (*Plate* XI. *Analyſis*, *fig*. 2.) deſcribed in the following manner: let the point C repreſent the centre of the earth, C A the earth's ſemidiameter, and A B any height above the ſurface; at A, place a right line A D, of any finite length, at right angles with A C. In the right line A C, towards C, take A β ſuch, that C A may be to A β in the proportion of C B to B A. In a right line drawn through β, at right angles with A C, take β E, of ſuch length, as to be to A D in the proportion of the denſity of the air at B to the denſity at A, the earth's ſurface. The curve, which the point E always touches, is a logarithmic, of which A C is the aſymptote; and is called by Dr. Horſley the atmoſpherical logarithmic.

Imagine this curve deſcribed, and take another height A *b*, and take Aϐ = $\frac{CA \times Ab}{Cb}$, and draw ϐ*e* parallel to β E, meeting the curve in *e*. Then βϐ is the logarithm of the ration of β E to ϐ *e*, or of the denſity at B to the denſity at *b*. But if the greater of the two heights, A B and A *b*, bear but a very ſmall proportion to the ſemidiameter of the earth, their difference B *b* will be very nearly equal to βϐ.

For, becauſe C B : B A = C A : A β by conſtruction.
Therefore, by converſion, C B : C A = C A : C β.
In like manner, and by inverſion, C A : C *b* = C ϐ : C A,
by equi-diſtance perturbate, C B : C *b* = C ϐ : C β,
and converting, C B : B *b* = C ϐ : ϐ β,
by permutation, B *b* : β ϐ = C B : C ϐ.

But when A B is infinitely diminiſhed, C B = C A ultimately. Alſo A *b* being infinitely diminiſhed, C ϐ = C A ultimately. Therefore C B = C ϐ ultimately, and B *b* = β ϐ ultimately. Q. E. D.

Now A B and A *b* will always be ſo ſmall, with reſpect to C A, if B and *b* be ſuppoſed to repreſent any acceſſible places, that C B, C ϐ, and B *b*, β ϐ, may always, in this caſe, be conſidered as in their ultimate proportion of equality.

It is ſtill therefore to be admitted, as a principle, in practice, that the difference of elevation of any two places is as the difference of the tabular logarithms of the heights of the quickſilver in the barometer at the ſame time at both places; that is, it is the logarithm of the ratio of thoſe heights in *ſome* ſyſtem of logarithms. And the heights of the quickſilver being given by obſervation, the difference of elevation will be known, if that particular ſyſtem can be determined; that is, if the *modulus* of the ſyſtem, or the length of the ſubtangent of the curve D E *e* of that ſyſtem, can be aſcertained, in ſome known meaſure, as Engliſh fathoms, or Paris toiſes.

The eaſieſt method of doing this, that theory ſuggeſts, is to compare barometers at two ſtations, ſuppoſe B and *b*, each of a known elevation A B and A *b*, above the level of the ſea. For the logarithms of any given ratio, in different ſyſtems, are proportional to the ſubtangents; and the difference of elevation, B *b*, diminiſhed in the proportion of C B, (the diſtance of the higher ſtation from the earth's centre,) to C ϐ, (a third proportional to C *b*, the diſtance of the lower ſtation from the earth's centre, and C A, the earth's ſemidiameter,) is the logarithm of the ratio of the denſity at B, to the denſity at *b*, (that is, of the columns of quickſilver ſuſtained in the barometer at B and *b*,) in the atmoſpherical ſyſtem. Therefore, as the difference of the tabular logarithms of theſe columns, to the ſubtangent of the tabular ſyſtem, ſo ſhould B *b*, diminiſhed as hath been ſaid, (that is, ſo ſhould βϐ,) be to the ſubtangent of the atmoſpherical logarithmic. The utmoſt height to which we can aſcend, above the level of the ſea, is ſo ſmall, that the reduction of B *b* may, even in this inveſtigation, always be neglected. For, if A B were four Engliſh miles, which exceeds the greateſt acceſſible heights, even of the Peruvian mountains, and A ϐ three, β ϐ would be ſcarce one part in 500 leſs than B *b*. So that, by comparing barometers at different elevations, within a mile above the level of the ſea, the ſubtangent of the atmoſpherical curve might be determined, as it ſhould ſeem, without ſenſible error, by taking ſimply the difference of elevation, without reduction, for the logarithm of the ratio of the obſerved height of the quickſilver in the atmoſpherical ſyſtem.

The ſubtangent is different in length at different times; though M. de Luc has ſhewn, that it is conſtant in a given temperature; ſo that if the temperature of the air is $+ 16\frac{3}{4}$ of his ſcale, the difference of the tabular logarithms of the heights of the quickſilver in the barometer, gives the difference of elevation in 1000dths of a Paris toiſe; whence the number, which is the *modulus* of Briggs's ſyſtem, expreſſes the length of the ſubtangent of the atmoſpherical curve, ſuch as it is in that temperature, in 1000dths of a Paris toiſe, Phil. Tranſ. vol. lxiv. part i. p. 231, &c.

Logarithmic, or Logistic *Curve*, is a curve which obtained its name from its properties and uſes in explaining and conſtructing logarithms; becauſe its ordinates are in geometrical progreſſion, while the correſponding abſciſſas are in arithmetical progreſſion; ſo that the abſciſſas are the logarithms of the correſponding ordinates. Hence the curve may be conſtructed in the following manner. *Fig*. 3. *Plate* XI. *Analyſis.*

Upon any right line as an axis, take the equal parts A B, B C, C D, &c. or the arithmetical progreſſion A B, A C, A D, &c. and at the points A, B, C, D, &c. erect the perpendicular ordinates A P, B Q, C R, D S, &c. in a geometrical progreſſion, and the curve line drawn through the extremities of theſe ordinates P, Q, R, S, &c. is the logarithmic or logiſtic curve, its abſciſſas A B, A C, A D, being as the logarithms of the reſpective correſponding ordinates B Q, C R, D S, &c.

Hence, if any abſciſſa A N = x, its ordinate N O = y, A P = 1, and a = a certain conſtant quantity, or the modulus of the logarithms, then the equation of the curve is $x = a \times \log. y = \log. y^a$; the fluxion of which being taken, it will be $\dot{x} = \frac{a\dot{y}}{y}$; whence the following proportion,

$$\dot{y} : \dot{x} :: y : a;$$

but in any curve $\dot{y} : \dot{x} :: y :$ the ſubtangent A T, and therefore the ſubtangent to this curve, is every where equal to the ſame conſtant quantity a, the modulus of the logarithms.

To find the area contained between any two ordinates.—

Here the fluxion of the area $\dot{A}$, or $y\dot{x}$, is $y \times \frac{a\dot{y}}{y} = a\dot{y}$; which corrected gives $A = a\,(AP - y) = a\,(AP - NO) = a \times PV = AT \times PV$. That is, the area APON, between any two ordinates, is equal to the rectangle of the conſtant ſubtangent, and the difference of the ordinates. And hence, when the abſciſſa is infinite, or the laſt ordinate equal to zero; then the infinitely long area APZ is equal to $AT \times AP$, or double the triangle APT.

To find the content of the ſolid formed by the revolution of the curve about its axis AZ.—The fluxion of the ſolid $\dot{S} = py^2\dot{x} = py^2 \times \frac{a\dot{y}}{y} = pay\dot{y}$, where $p = 3.14159$, &c.; and the correct fluent is $S = \frac{1}{2}pa \times (AP^2 - y^2) = \frac{1}{2}p \times AT \times (AP^2 - NO^2)$, which is half the difference between two cylinders of the common altitude a, or AT, and the radii of their baſes AP, NO. And hence, ſuppoſing the axis infinite towards Z, and conſequently the ordinate at its extremity zero, the content of the infinitely long ſolid will be equal to $\frac{1}{2}pa \times AP^2 = \frac{1}{2}p \times AT \times AP^2$, or half the cylinder on the ſame baſe and its altitude AT.

This curve greatly facilitates the conception of logarithms, and affords a very obvious proof of the very important property of their fluxions, or very ſmall increments; namely, that the fluxion of a number, is to the fluxion of its logarithm as the number is to the ſubtangent. As alſo this property, that if their numbers be taken very nearly equal, ſo that their ratios may differ but a little from a ratio of equality, their difference will be very nearly proportional to the logarithm of the ratio of theſe numbers to each other; which follows from the logarithmic arcs being very little different from their chords when they are taken very ſmall. The conſtant ſubtangent of this curve is, what Cotes calls, the modulus of the ſyſtem of logarithms. This curve has been treated of by a great number of very eminent mathematicians, as Huygens, Le Seur, Keil, Bernouilli, Emerſon, &c. See the latter author's Treatiſe on Curve Lines, page 19.

LOGARITHMIC, *Hyperbolic*. See HYPERBOLIC *Logarithms*.

LOGARITHMIC, or *Logarithmical*, relating to logarithms. Thus we ſay, logarithmic *arithmetic*, *curve*, *line*, *ſcale*, *ſpiral*.

LOGARITHMS, formed from the Greek λογος, *ratio*, and αριθμος, *number*; q. d. *ratio of numbers*; the indices of the ratios of numbers one to another; or a ſeries of artificial numbers proceeding in arithmetical proportion, correſponding to as many others proceeding in geometrical proportion; contrived for the eaſing and expediting of calculation.

LOGARITHMS have been uſually defined *numerorum proportionalium æquidifferentes comites*; but this definition Dr. Halley and Stifelius think deficient, and more accurately define them, *the indices or exponents of the ratios of numbers*; ratio being conſidered as a quantity *ſui generis*, beginning from the ratio of equality, or 1 to 1 = 0, and being affirmative when the ratio is increaſing, and negative when it is decreaſing. But a more ſimple idea of theſe numbers may be formed from the following definition, *viz.* The logarithm of a number is that exponent of ſome other number, which renders the power of the latter equal to the former: thus if $r^x = a$, $r^y = b$, $r^z = c$, &c. then is x the logarithm of a; y the logarithm of b; z the logarithm of c, &c. Alſo r is then called the radix of the ſyſtem, which may be aſſumed at pleaſure; but in the common tables the radix is always 10.

We will conſider theſe numbers under each of the two latter definitions. According to the firſt; if unity be made the common conſequent of all ratios, or the common ſtandard to which all other numbers are to be referred, then every logarithm will be the numeral exponent of the ratio of its natural number to unity. *E. gr.* the ratio of 81 to 1 contains the four following ratios, *viz.* that of 81 to 27, 27 to 9, 9 to 3, and 3 to 1, or $\frac{81}{1} = \frac{81}{27} \times \frac{27}{9} \times \frac{9}{3} \times \frac{3}{1}$; but all theſe ratios are equal to one another, and $\frac{81}{1} = \frac{3}{1} \times \frac{3}{1} \times \frac{3}{1} \times \frac{3}{1} = \overline{\tfrac{3}{1}\big)}^4$; conſequently the logarithm of 81, is four times as great as that of 3. In the ſame manner, the ratio of 24 to 1, or $\frac{24}{1} = \frac{24}{12} \times \frac{12}{4} \times \frac{4}{1} = \frac{2}{1} \times \frac{3}{1} \times \frac{4}{1}$; and, therefore, the logarithm of 24 is equal to the ſum of the logarithms of 2, 3, and 4. And, univerſally, the magnitude of the ratio of A to 1, is to the magnitude of the ratio of B to 1, as the logarithm of A to the logarithm of B. Hence we derive a method of meaſuring all ratios whatever, let their conſequents be what they will: *e. g.* the ratio of A to B, is the exceſs of the ratio of A to 1, above the ratio of B to 1; therefore the numeral exponent of the ratio of A to B, will be the exceſs of the numeral exponent of the ratio of A to 1, above the numeral exponent of the ratio of B to 1, that is, the exceſs of the logarithm of A above the logarithm of B: therefore the magnitude of the ratio of A to B is to the magnitude of the ratio of C to D as the exceſs of the logarithm of A above the logarithm of B, which is the meaſure of the former ratio, is to the exceſs of the logarithm of C above that of D, which is the meaſure of the latter ratio: and thus we ſee that logarithms are as true and proper meaſures of ratios, as circular arcs are of angles.

The nature and genius of logarithms will be eaſily conceived from what follows:—A ſeries of quantities increaſing or decreaſing according to the ſame ratio is called a *geometrical progreſſion*; *e. gr.* 1. 2. 4. 8. 16. 32, &c. A ſeries of quantities increaſing or decreaſing, according to the ſame difference, is called an *arithmetical progreſſion*; *e. gr.* 3. 6. 9. 12. 15. 18. 21. Now, if under the numbers proceeding in a geometrical ratio, be placed as many of thoſe proceeding in the arithmetical one, theſe laſt are called the logarithms of the firſt.

Suppoſe *e. gr.* two progreſſions:

Geomet.	1.	2.	4.	8.	16.	32.	64.	128.	256.	512.
Arithmet.	0.	1.	2.	3.	4.	5.	6.	7.	8.	9.

Logarithms.

0 will be the logarithm of the firſt term; *viz.* 1; 5, of the 6th, 32; 7, the logarithm of the 8th, 128, &c.

Theſe indices or logarithms may be adapted to any geometric ſeries; and, therefore, there may be as many kinds of indices or logarithms, as there can be taken kinds of geometric ſeries; but the logarithms moſt convenient for common uſe, are thoſe adapted to a geometrical ſeries increaſing in a ten-fold progreſſion, as in the ſequel. The doctrine and uſe of logarithms may be conceived from the following propoſitions.

1. *If the logarithm of unity be* 0, *the logarithm of the factum or product will be equal to the ſum of the logarithms of the factors.*—For as unity is to one of the factors, ſo is the other factor to the product. So that the logarithm of the product is a fourth equidifferent term to the logarithm of unity, and thoſe of the factors; but the logarithm of unity being 0, the ſum of the logarithms of the factors muſt be the logarithm of the factum, or product. Q. E. D. Hence, ſince the factors of a ſquare are equal to each other, *i. e.* a ſquare is the factum or product of its root multiplied into itſelf, the logarithm of the ſquare will be double the logarithm of the root.

In the ſame manner it appears, that the logarithm of the cube is triple; of the biquadrate, quadruple; of the fifth power, quintuple; of the ſixth, ſextuple, &c. of the logarithm of the root.

Unity, therefore, is to the exponent of the power, as the logarithm of the root to the logarithm of the power.

So that the logarithm of the power is had, if the logarithm of the root be multiplied by its exponent; and the logarithm of the root is had, if the logarithm of the power be divided by its exponent.

And hence we derive one of the great uſes of logarithms, which is to expedite and facilitate the buſineſs of multiplication, involution of powers, and extraction of roots; the former of which is here performed by mere addition, and the two latter by multiplication and diviſion. Thus 3, the ſum of the logarithms 1 and 2, is the logarithm of 8, the product of 2 and 4. In like manner 7, the ſum of the logarithms 2 and 5, is the logarithm of 128, the product of 4 and 32. Again, 6, the logarithm of 64, which is the third power of 4, or 4^3, is equal to 3 × 2. And 8, the logarithm of 256, which is the fourth power of 4, or 4^4, is equal to 4 × 2. Moreover, 3. the logarithm of the ſquare root 8, is half the logarithm 6, of the ſquare 64; and 2, the logarithm of the cube root 4, is one-third the logarithm 6 of the cube 64.

2. *If the logarithm of unity be* 0, *the logarithm of the quotient will be equal to the difference of the logarithms of the diviſor and dividend.*—For as the diviſor is to the dividend, ſo is unity to the quotient; therefore the logarithm of the quotient is a fourth equidifferent number to the logarithms of the diviſor, the dividend, and the logarithm of unity. The logarithm of unity, therefore, being 0, the difference of the logarithm of the diviſor, and that of the dividend, is the logarithm of the quotient. Q. E. D.

Hence appears another great advantage of logarithms; *viz.* their expediting the buſineſs of diviſion, and performing it by a bare ſubtraction. *E. gr.* 2, the difference between 7 and 5, is the logarithm of the quotient 4, obtained by dividing 128 by 32. In like manner, 5, the difference between 8 and 3, is the logarithm of the quotient 32, obtained by dividing 256 by 8.

Theſe properties of logarithms, however, are more obvious according to our latter definition. For in that caſe, if $r^x = a$, and $r^y = b$, x and y being the logarithms of a and b, we have immediately from the firſt principles of algebra,

$$r^x \times r^y = r^{x+y} = ab \qquad \text{Multiplication.}$$

$$r^x \div r^y = r^{x-y} = \frac{a}{b} \qquad \text{Diviſion.}$$

$$(r^x)^n = r^{x \times n} = r^{xn} = a^n \qquad \text{Involution.}$$

$$\sqrt[n]{r^x} = r^{x \div n} = r^{\frac{x}{n}} = \sqrt[n]{a} \qquad \text{Evolution.}$$

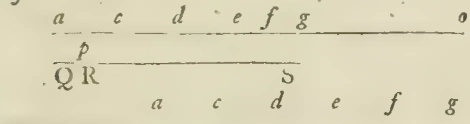
From which formulæ it is evident, that the logarithm of the product of a multiplied by b is equal to the ſum of the logarithms of a and b. The logarithm of the quotient of a divided by b, is equal to the difference of the logarithms of a and b. The logarithm of the nth power of a is equal to n times the logarithm of a. And the logarithm of the nth root of a, is equal to the logarithm of a divided by n. Therefore, univerſally, to multiply two numbers together, we muſt take the ſum of their logarithms: to divide one number by another, we ſubtract the logarithm of the latter from the logarithm of the former. To involve a number to any power, we muſt multiply its logarithm by the index of the power. And to extract the root of any number, we muſt divide its logarithm by the index of the power of which the root is to be found. But each of theſe rules will require a more particular illuſtration, which will be found in the ſubſequent part of this article.

The properties of logarithms hitherto mentioned, and their various uſes, are taken notice of by Stifelius: but they come all far ſhort of the uſe of logarithms in trigonometry, firſt diſcovered by John Napier, baron of Merchiſton, in Scotland, and firſt publiſhed at Edinburgh in 1614, in his Mirifici Logarithmorum Canonis Deſcriptio. This work was tranſlated by Mr Edward Wright, and publiſhed by his ſon, with the aſſiſtance of Mr. Briggs, in the year 1616 or 1618. The method of conſtructing the table was reſerved by the ingenious author, till the ſenſe of the learned upon his invention ſhould be known; nevertheleſs Kepler, in his Chilias Logarithmorum ad totidem Numeros rotundos, publiſhed at Marpurg in 1724; Speidell in his New Logarithms, publiſhed in 1619, and republiſhed with conſiderable additions, in a ſixth impreſſion in 1624; Benj. Urſinius, in his Table of Logarithms, printed at Cologne in 1625, and others, at home and abroad, laboured at the computation of logarithms, and conſtructed ſmall tables, conformable to the plan of lord Napier. But of all thoſe who aſſiſted in the conſtruction of logarithmic tables, Briggs is moſt conſpicuous; it was he who firſt ſuggeſted our preſent ſyſtem, and laboured more than any one in the computation of the numbers it contains. In the preſent ſtate of analyſis many comparatively ſhort and eaſy methods may be employed for this purpoſe, that were unknown to the early writers; and for want of which the labour attending the firſt computation was exceedingly great; ſome idea of which may be formed from the following illuſtration.

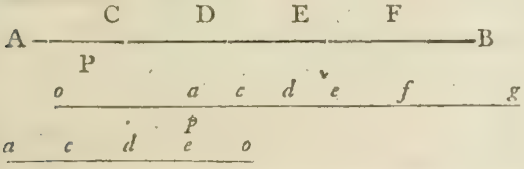
To find the logarithm of any number, according to Briggs's method.—1. Becauſe, 1. 10. 100. 1000. 10000, &c. conſtitute a geometrical progreſſion, their logarithms may be taken at pleaſure: to be able, then, to expreſs the logarithms of the intermediate numbers by decimal fractions, take 0.00000000, 1.00000000, 2.00000000, 3.00000000, 4.00000000. &c. 2. It is manifeſt, that for thoſe numbers which are not contained in the ſcale of geometrical progreſſion, the juſt logarithms cannot be had: yet they may be had ſo near the truth, that, as to matters of uſe, they ſhall be altogether as good as if ſtrictly juſt. To make this appear, ſuppoſe the logarithm of the number 9 were required; between 1.0000000 and 10.0000000, find a mean proportional, and between their logarithms 0.00000000, and 1.00000000 an equidifferent mean, which will be the logarithm thereof; that is, of a number exceeding three by $\frac{1622777}{10000000}$, and therefore far remote from nine. Between 3 and 10, therefore, find another mean proportional, which may come ſomewhat nearer 9; and between 10 and this mean another ſtill; and ſo on between the numbers next greater and next leſs than 9, till at laſt you arrive at 9 $\frac{1}{100000000}$; which not being one millionth part from 9, its logarithm may, without any ſenſible error, be taken for that of 9 itſelf. Seeking then in each caſe for the logarithms of the mean proportionals, you will at laſt have 0.954251, which is exceedingly near the true logarithm of 9. 3. If in like manner you find mean proportionals between 1.0000000 and 3.1622777, and aſſign the proper logarithms to each, you will at length have the logarithm of the number 2, and ſo of the reſt.

Such was the method employed by the early computors of logarithms: and though they had certain means of abridging the operations in particular caſes, yet it is evident that the computation of them was not effected without immenſe labour; a particular and intereſting account of which, with an explanation of the ſeveral modifications of the above method made uſe of by different authors, may be ſeen in the introduction to Dr. Hutton's Mathematical Tables. It is unneceſſary to obſerve, that theſe computations were only required for prime numbers; for theſe being once obtained, the logarithms of all other numbers were found by ſimple addition. At preſent, we have only ſpoken of logarithms as they are applicable to numerical computations. But they are alſo of very extenſive uſe in the higher geometry, particularly in the doctrine of fluxions, and it will not be amiſs, before we quit this part of the ſubject, to give an idea of the way in which they have been conſidered by writers on the latter ſcience. Maclaurin, in his Treatiſe of Fluxions, has explained the nature and geneſis of logarithms, agreeably to the notion of their firſt inventor, lord Napier, delivered in his Mirif. Logar. Canon. Deſcript. He there ſuppoſes logarithms, and the quantities to which they correſpond, to be generated by the motion of a point. If this point moves over equal ſpaces in equal times, the line deſcribed by it increaſes equally.

Again, a line decreaſes proportionally when the point that moves over it deſcribes ſuch parts in equal times as are always in the ſame conſtant ratio to the lines from which they are ſubducted, or to the diſtances of that point at the beginning of thoſe times, from a given term in the line. In like manner, a line may increaſe proportionally, if in equal time the moving point deſcribes ſpaces proportional to its diſtances from a certain term, at the beginning of each time. Thus, in the firſt caſe, let *ac* be to *ao*, *cd* to *co*, *de* to *do*, *ef* to *eo*, *fg* to *fo*, always in the ſame ratio of Q R to Q S; and ſuppoſe that the point *p* ſets out from *a*, deſcribing *ac*, *cd*, *de*, *ef*, *fg*, in equal parts of the time; and let the ſpace deſcribed by *p*, in any given time, be always in the ſame ratio to the diſtance of *p* from *o*, at the beginning of that time, then will the right line *ao* decreaſe proportionally; and the lines *ao*, *co*, *do*, *eo*, *fo*, &c. or the diſtances of the point *p* from *o*, at equal ſucceeding intervals of time, are in a continued geometrical progreſſion.



In like manner, the line *oa* increaſes proportionally, if the point *p* in equal times deſcribes ſpaces *ac*, *cd*, *de*, *ef*, *fg*, &c. ſo that *ac* is to *ao*, *cd* to *co*, *de* to *do*, &c. in a conſtant ratio.



If we now ſuppoſe a point P deſcribing the line A B with an uniform motion, equal to that with which *p* ſets out from *a*, in deſcribing the line *ao*, while the point *p* deſcribes a line increaſing or decreaſing proportionally, the line A P deſcribed by P with this uniform motion, in the ſame time that *oa*, by increaſing or decreaſing proportionally, becomes equal to *op*, is the logarithm of *op*. Thus A C, A D, A E, &c. are the logarithms of *oc*, *od*, *oe*, &c. reſpectively; and *oa* is the quantity whoſe logarithm is ſuppoſed equal to nothing.

We have here abſtracted from numbers, that the doctrine may be the more general; but it is plain, that if A C, A D, A E, &c. be ſuppoſed 1, 2, 3, &c. in arithmetic progreſſion; *oc*, *od*, *oe*, &c. will be in geometric progreſſion; and that the logarithm of *oa*, which may be taken for unity, is nothing.

Lord Napier, in his firſt ſcheme of logarithms, ſuppoſes, that while *op* increaſes or decreaſes proportionally, the uniform motion of the point P, by which the logarithm of *op* is generated, is equal to the velocity of *p* at *a*; that is, at the term of time when the logarithms begin to be generated. Hence logarithms, formed after this model, are called *Napier's* logarithms, and ſometimes *natural* logarithms.

When the ratio is given, the point *p* deſcribes the difference of the terms of the ratio in the ſame time. When a ratio is duplicate of another ratio, the point *p* deſcribes the difference of the terms in a double time. When a ratio is triplicate of another, it deſcribes the difference of the terms in a triple time; and ſo on. Alſo, when a ratio is compounded of two or more ratios, the point *p* deſcribes the difference of the terms of that ratio, in a time equal to the ſum of the times in which it deſcribes the differences of the terms of the ſimple ratios of which it is compounded. And what is here ſaid of the times of the motion of *p*, when *op* increaſes proportionally, is to be applied to the ſpaces deſcribed by P in thoſe times, with its uniform motion.

Hence the chief properties of logarithms are deduced. They are the meaſures of ratios. The exceſs of the logarithm of the antecedent above the logarithm of the conſequent meaſures the ratio of thoſe terms. The meaſure of the ratio of a greater quantity to a leſſer is poſitive, as this ratio compounded with any other ratio increaſes it. The ratio of equality, compounded with any other ratio, neither increaſes nor diminiſhes it; and its meaſure is nothing. The meaſure of the ratio of a leſſer quantity to a greater is negative, as this ratio compounded with any other ratio diminiſhes it. The ratio of any quantity A to unity, compounded with the ratio of unity to A, produces the ratio of A to A, or the ratio of equality; and the meaſures of thoſe two ratios deſtroy each other, when added together: ſo that when the one is conſidered as poſitive, the other is to be conſidered as negative.

When *op* increaſes proportionally, the motion of *p* is perpetually accelerated; and, on the contrary, when *op* decreaſes proportionally, the motion of *p* is perpetually retarded.

If the velocity of the point *p* be always as the diſtance *op*, then will this line increaſe or decreaſe in the manner ſuppoſed by lord Napier: and the velocity of the point *p* being the fluxion of the line *op*, will always vary in the ſame ratio as this quantity itſelf. See Maclaurin's Flux. art. 151—160.

The fluxion of any quantity is to the fluxion of its logarithm, as the quantity itſelf is to unity.

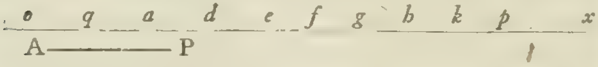
Hence the fluxion of the logarithm of x will be $\frac{\dot{x}}{x}$

For $x : 1 :: \dot{x} : \frac{\dot{x}}{x}$ = the fluxion of the logarithm required.

When *op* increaſes proportionally, the increments generated in any equal times, are accurately in the ſame ratio as the velocities of *p*, or the fluxions of *op*, at the beginning, end, or at any ſimilar terms of thoſe times.

When *op* increaſes, or decreaſes proportionally, the fluxions of this line, in all the higher orders, increaſe or decreaſe in the ſame proportion as the line itſelf increaſes or decreaſes; ſo that one rule ſerves for comparing together, thoſe of any kind at different terms of time; and in this caſe we never arrive at any conſtant or invariable fluxion. If the logarithms of two quantities be always to each other in any invariable ratio, the fluxions of thoſe quantities ſhall be in a ratio that is compounded of a ratio of the quantities themſelves, and of the invariable ratio of their logarithms.

Let *op* be greater than *oa*; *ad* : *ap* : : *oa* : *op*; and let *oa*, *ad*, *de*, *ef*, *fg*, &c. be in continued proportion: then by adding together *ad*, $\frac{1}{2}$ *de*, $\frac{1}{3}$ *ef*, $\frac{1}{4}$ *fg*, &c. we approximate continually to the value of A P, the logarithm of *op*. And we approximate continually to the logarithm of *od*, by ſumming up the differences betwixt *ad* and $\frac{1}{2}$ *de*, $-\frac{1}{3}$ *ef*, and $\frac{1}{4}$ *fg*, $\frac{1}{5}$ *gh* and $\frac{1}{6}$ *hk*, &c. See Maclaurin's Fluxions, art. 171, 172. From what has been ſaid, it follows, that if *ao* : *od* : : *op* : *ox*, then the logarithm of *ox* will be equal to the ſum of the logarithms of *op* and *od*: that is, to the ſum of $ad + \frac{1}{2}de + \frac{1}{3}ef + \frac{1}{4}fg + \frac{1}{5}gh + \frac{1}{6}hk$, &c. and $ad + \frac{1}{2}de + \frac{1}{3}ef - \frac{1}{4}fg - \frac{1}{5}gh + \frac{1}{6}hk$, &c. and $ad - \frac{1}{2}de + \frac{1}{3}ef - \frac{1}{4}fg + \frac{1}{5}gh - \frac{1}{6}hk$, &c. which ſum is $2\,ad + \frac{2}{3}ef + \frac{2}{5}gh$, &c.



Let $aq = ad$; then the logarithm of *ox* will meaſure the ratio of *od* to *oq*. But *od* and *oq* have half their ſum equal to *oa*, and half their difference equal to *ad*, which are the two firſt terms of the geometric progreſſion *oa*, *ad*, *de*, *ef*, *fg*, *gh*, *hk*, &c. Hence, if $oa = 1$, and $ad = x$, *de*, *ef*, *fg*, &c. will be reſpectively, x^2, x^3, x^4, &c. and the ratio of $1 + x$ to $1 - x$ will be equal to that of *od* to *oq*. But the logarithm of this ratio is $2\,ad + \frac{2}{3}ef + \frac{2}{5}gh +$, &c. therefore the logarithm of $\frac{1+x}{1-x} = 2 \times \overline{x + \frac{1}{3}x^3 + \frac{1}{5}x^5 + \frac{1}{7}x^7 + \text{\&c.}}$ agreeably to what has been ſhewn by Dr. Halley and others.

Having thus given an idea of the forms under which logarithms were conſidered, and the methods by which they were computed by ſome of the early writers on this ſubject, it will be proper now to beſtow a few columns, to explain the more modern way of inveſtigating the principles and of computing theſe very uſeful numbers; in doing which, however, the limits of our article will neceſſarily confine our obſervation to only the moſt popular and uſeful formulæ.

We have already defined a logarithm to be the index of a certain number called the radix, which being raiſed to the power denoted by that index or logarithm, will produce the given number. If, therefore, $r^x = N$, then x is the logarithm of N, and r is the radix of the ſyſtem. Now, firſt, in order to find an analytical expreſſion for N in terms of x and r; r^x muſt be converted into a ſeries, for which purpoſe it may be put under the form

$$r^x = (1 + (r-1))^x = 1 + x(r-1) + \frac{x.(x-1)}{1.2}$$

$$(r-1)^2 + \frac{x(x-1)(x-2)}{1.2.3}(r-1)^3 + \text{\&c.}$$

$$= 1 + x\left\{(r-1) - \tfrac{1}{2}(r-1)^2 + \tfrac{1}{3}(r-1)^3 - \text{\&c.}\right\}$$

$$+ \frac{x^2}{1.2}\left\{(r-1)^2 - (r-1)^3 + \text{\&c.}\right\} =$$

$$1 + Ax + A'x^2 + A''x^3 + \text{\&c.}$$

by writing

$$A = (r-1) - \tfrac{1}{2}(r-1)^2 + \tfrac{1}{3}(r-1)^3 - \text{\&c.}$$
$$A' = (r-1)^2 - (r-1)^3 + \text{\&c.}$$
$$A'' = \text{\&c.}$$

where A, A′, A″, A‴, &c. are conſtant but unknown quantities. And now, in order to determine the law by which they are connected with each other, let x be increaſed by any indeterminate quantity z; then $r^{x+z} = 1 + A(x+z) + A'(x+z)^2 + A''(x+z)^3 \ldots\ldots A^{(n-1)}(x+z)^n$; or, expanding the powers of $x + z$, and ſtopping at the firſt two terms, we have

$$\begin{aligned} r^{x+z} = 1 &+ A(x+z) \\ &+ A'(x^2 + 2xz + \text{\&c.}) \\ &+ A''(x^3 + 3x^2z + \text{\&c.}) \\ &+ A^{(n-1)}(x^n + nx^{n-1}z + \text{\&c.}) \\ &+ A^{(n)}(x^{n+1} + (n+1)x^n + \text{\&c.}) \end{aligned}$$

Again

$$r^{x+z} = r^x \times r^z =$$
$$(1 + Ax + A'x^2 + A''x^3 + \text{\&c.}) \times$$
$$(1 + Az + A'z^2 + A''z^3 + \text{\&c.})$$

the actual multiplication of which gives

$$\begin{aligned} r^{x+z} = 1 + A(x+z) + A'x^3 + A''x^3 \ldots A^{(n-1)}x^n \\ A^2xz + A'.Ax^2z \ldots \text{\&c.} \end{aligned}$$

whence, by comparing the correſponding terms in the two expanſions, we have

$$2A' = A^2, \text{ or } A' = \frac{A^2}{2};\quad 3A'' = AA' = \frac{A^3}{2};$$

and therefore $A'' = \frac{A^3}{1.2.3}$

in the ſame way $A''' = \frac{A^4}{1.2.3.4}$

and generally $A^{(n-1)} = \frac{A^n}{1.2.3\ldots n}$

$$A^n = \frac{A^{n+1}}{1.2.3\ldots(n+1)}$$

And conſequently,

$$r^x = N = 1 + Ax + \frac{A^2}{1.2}x^2 + \frac{A^3}{1.2.3}x^3 + \text{\&c.}$$

which is the analytical expreſſion for any number in terms of the radix r and its logarithm x; but the reverſe of this, by which the logarithm is expreſſed in terms of its number and radix, is the formula which is more particularly applicable in the preſent enquiry. This may be found as follows.

In the preceding article we found

$$r = N = 1 + Ax + \frac{A^2}{1.2}x^2 + \frac{A^3}{1.2.3}x^3 + \text{\&c.}$$

where $A = (r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \text{\&c.}$; and if now we make

$$B = (N-1) - \tfrac{1}{2}(N-1)^2 + \tfrac{1}{3}(N-1)^3 - \text{\&c.}$$

we ſhall have on the ſame principles

$$N^z = 1 + Bz + \frac{B^2}{1.2}z^2 + \frac{B^3}{1.2.3}z^3 + \text{\&c.}$$

But

$$N^z = r^{xz} = 1 + Axz + \frac{A^2}{1.2}x^2z^2 + \frac{A^3}{1.2.3}x^3z^3 +$$

&c.; whence, by comparing the co-efficients of z in both ſeries, we have

$$A\,x = B\,;\ \frac{A^2x^2}{1\,.\,2} = \frac{B^2}{1\,.\,2}\,;\ \frac{A^3x^3}{1\,.\,2\,.\,3} = \frac{B^3}{1\,.\,2\,.\,3}\ \&c.;$$

each of which gives the ſame reſult, *viz.* $A\,x = B$; whence we obtain immediately

$$x = \frac{B}{A} = \frac{(N-1) - \frac{1}{2}(N-1)^2 + \frac{1}{3}(N-1)^3 - \ \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1) - \ \&c.}$$

which is the analytical expreſſion for the logarithm of any number N, in functions of itſelf, and the radix of the ſyſtem; that is, writing a inſtead of N

$$\log.\ a = \frac{(a-1) - \frac{1}{2}(a-1)^2 + \frac{1}{3}(a-1)^3 - \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \&c.}$$

$$\text{Or, } \log.\ 1 \pm a = \frac{\pm a - \frac{1}{2}a^2 \pm \frac{1}{3}a^3 - \frac{1}{4}a^4 \pm \ \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \&c.}$$

This, however, muſt only be conſidered as a ſimple algebraical method of expreſſing a logarithm; but it does not always anſwer the purpoſes of calculation, for if a be any number greater than unity, it is obvious that the ſeries in the numerator will either converge very ſlowly, or otherwiſe will diverge, and the ſame with regard to the denominator, ſuppoſing r to be equal to 10, as it is in the common ſyſtem; in fact, the terms of the ſeries are larger the more remote they are from the beginning; and conſequently no number of them can exhibit, either exactly or nearly, the true ſum. Let us, therefore, inveſtigate the method of ſubmitting theſe to calculation; in order to which we will repeat again our laſt ſeries, *viz.*

$$\log.\ 1 \pm a = \frac{\pm a - \frac{1}{2}a^2 \pm \frac{1}{3}a^3 - \frac{1}{4}a^4 \pm \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \&c.}$$

and here, ſince the denominator is always a conſtant quantity when the radix of the ſyſtem is given, we may make

$$M = (r-1) - \tfrac{1}{2}(r-1)^2 + \tfrac{1}{3}(r-1)^3 - \ \&c.$$

which renders the above expreſſion ſtill more ſimple, as in that caſe it becomes barely

$$\log.\ 1 + a = \frac{1}{M} \times \left\{ a - \tfrac{1}{2}a^2 + \tfrac{1}{3}a^3 - \tfrac{1}{4}a^4 + \&c. \right\}$$

Or, taking a negative,

$$\log.\ 1 - a = \frac{1}{M} \times \left\{ -a - \tfrac{1}{2}a^2 - \tfrac{1}{3}a^3 - \tfrac{1}{4}a^4 - \&c. \right\}$$

Whence again by ſubtraction,

$$\log.\left(\frac{1+a}{1-a}\right) = \frac{2}{M}\left\{ a + \tfrac{1}{3}a^3 + \tfrac{1}{5}a^5 + \tfrac{1}{7}a^7 + \ \&c. \right\}$$

Now $a = \dfrac{1 + \frac{a-1}{a+1}}{1 - \frac{a-1}{a+1}}$; if, therefore, we ſubſtitute in the foregoing expreſſion $\dfrac{a-1}{a+1}$ inſtead of a, it becomes

$$\log.\ a = \frac{2}{M} \times \left\{ \left(\frac{a-1}{a+1}\right) + \tfrac{1}{3}\left(\frac{a-1}{a+1}\right)^3 + \tfrac{1}{5}\left(\frac{a-1}{a+1}\right)^5 + \ \&c. \right\}$$

which ſeries muſt neceſſarily converge; becauſe the denominator of each of the fractions is greater than its numerator; ſtill, however, when a is a number of any conſiderable magnitude, the decreaſe in the terms will be ſo ſlow as to render the formula uſeleſs for the purpoſes of calculation.

At preſent we have aſſumed the ſeries which conſtitutes the denominator in our firſt expreſſion a known quantity, which we have repreſented by M. It will, however, be proper, before we proceed any farther, to offer a few remarks upon the abſolute value of this ſeries, according to any given radix. Firſt then, ſince

$$\log.\ 1 + a = \frac{a - \frac{1}{2}a^2 + \frac{1}{3}a^3 - \frac{1}{4}a^4 + \ \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \ \&c.}$$

the denominator and numerator of this fraction are totally independent of each other, and therefore r may be aſſumed at pleaſure, and the value of the whole denominator computed for any particular magnitude aſſigned to this letter: or otherwiſe, the whole denominator may be taken equal to any quantity, and the value of r itſelf determined by computation. The latter method, at firſt ſight, appears the moſt eligible; for by aſſuming the whole denominator equal to unity, it diſappears entirely, and the expreſſion becomes

$$\log.\ (1 + a) = a - \tfrac{1}{2}a^2 + \tfrac{1}{3}a^3 - \tfrac{1}{4}a^4 + \ \&c.$$

There are, however, inconveniences attending this ſyſtem, that do not appear upon a ſlight view of the ſubject, but which are notwithſtanding very evident upon a farther inveſtigation. In the caſe in which the whole denominator is aſſumed equal to unity, the value of r, the radix of this particular ſyſtem, is found to be 2.7182818284, &c. and the fraction $\frac{1}{M}$ becomes $= 1$. Theſe conſtitute what are called *hyperbolic logarithms*, and which are treated of under that article in the preſent work. We ſhall, therefore, enter no farther upon the ſubject in this place, than is neceſſary to ſhew the defect of this ſyſtem for general purpoſes, when compared with that now in common uſe, a defect which is by no means compenſated by the trifling advantage attending their computation. In the common ſyſtem the radix r is aſſumed equal to 10, the ſame as the radix of our ſcale of notation; and hence ariſes a moſt important advantage, which is, that the logarithm of all numbers expreſſed by the ſame digits, whether integers, decimals, or mixed of the two, have the ſame decimal part; the only alteration being in the index or characteriſtic of the logarithm. For the radix being 10, 0, 1, 2, 3, &c. will be logarithms of 1, 10, 10^2, &c. that is, $10^0 = 1$, $10^1 = 10$, $10^2 = 100$, &c.; and therefore, to multiply or divide a number by any power of 10, we have only to add or ſubtract the number expreſſing that power from the integral part of the logarithm, and the decimal part will ſtill remain the ſame, by which means the tables of logarithms are much more contracted than they could be with any other radix; for in the hyperbolic ſyſtem, or in any other, which has not its radix the ſame as that of the ſcale of notation, every particular number would require a particular logarithm; and this circumſtance would either ſwell the tables to an unmanageable ſize, or if they were kept within the preſent limits, frequent computations would become neceſſary; ſo that in either way it is clear that the advantages of the preſent logarithms much more than counterbalance the extra trouble in computing them. This in fact only conſiſts in multiplying the hyperbolic logarithm by a conſtant factor; *viz.* the reciprocal of the foregoing conſtant denominator repreſented above by $\frac{1}{M}$, the value of which, when $r = 10$, is $\dfrac{1}{2.30258509, \&c.} = .43429448$, &c. Hence it is obvious, that different ſyſtems of logarithms are connected together by conſtant multipliers, and by means of which a logarithm may always be converted from one ſcale to another. Thus the hyperbolic logarithm of a number is transformed to the common logarithm, by multiplying the former by .4342944; and the latter is converted into the former by multiplying it by 2.30258509.

Having ſaid thus much with regard to advantages of different ſyſtems of logarithms, and the method of transforming them from one ſcale to another; we will now add one example by way of illuſtration. Let it therefore be propoſed to find the common logarithm of 3. In this caſe our

$$\text{ſeries log. } a = \frac{2}{M} \times \left\{ \left(\frac{a-1}{a+1}\right) + \tfrac{1}{3}\left(\frac{a-1}{a+1}\right)^3 + \tfrac{1}{5}\left(\frac{a-1}{a+1}\right)^5 \text{ \&c.} \right\}$$

$$\text{becomes log. } 3 = \frac{2}{M} \times \left\{ \frac{1}{2} + \frac{1}{3 \cdot 2^3} + \frac{1}{5 \cdot 2^5} + \frac{1}{7 \cdot 2^7} + \text{ \&c.} \right\}$$

the computation of which will ſtand thus:

$\frac{1}{2}$ = - - - - - .5

$\frac{1}{3 \cdot 2^3}$ = - - - - - .0416666666

$\frac{1}{5 \cdot 2^5}$ = - - - - - .00625

$\frac{1}{7 \cdot 2^7}$ = - - - - - .0011160714

$\frac{1}{9 \cdot 2^9}$ = - - - - - .0002170138

$\frac{1}{11 \cdot 2^{11}}$ = - - - - - .0000443892

$\frac{1}{13 \cdot 2^{13}}$ = - - - - - .0000093900

$\frac{1}{15 \cdot 2^{15}}$ = - - - - - .0000020345

$\frac{1}{17 \cdot 2^{17}}$ = - - - - - .0000004487

$\frac{1}{19 \cdot 2^{19}}$ = - - - - - .0000001003

$\frac{1}{21 \cdot 2^{21}}$ = - - - - - .0000000227

$\frac{1}{23 \cdot 2^{23}}$ = - - - - - .0000000050

.5493061422

whence $\frac{2}{2.30258509}$, or 43429448 × 5493061422 = .4771212, which is the logarithm of 3 required.

This ſeries, we have already obſerved, will only anſwer for the computation of the logarithms of ſmall numbers, in other caſes different ſeries muſt be employed according to the particular number under conſideration. The limits of this article will not admit of an inveſtigation of the ſeparate caſes. But for the ſake of reference it will be uſeful to ſubjoin a few of the moſt uſeful formulæ, for which purpoſe we avail ourſelves of the ſelection made by Mr. Bonnycaſtle, in his valuable treatiſe of Trigonometry.

$$1.\ \text{Log. } a = \frac{1}{M} \times \left\{ (a-1) - \tfrac{1}{2}(a-1)^2 + \tfrac{1}{3}(a-1)^3 -, \text{ \&c.} \right\}$$

$$2.\ \text{Log. } a = \frac{1}{M} \times \left\{ \left(\frac{a-1}{a}\right) + \tfrac{1}{2}\left(\frac{a-1}{a}\right)^2 + \tfrac{1}{3}\left(\frac{a-1}{a}\right)^3 - \text{ \&c.} \right\}$$

$$3.\ \text{Log. } a = \frac{2}{M} \times \left\{ \left(\frac{a-1}{a+1}\right) + \tfrac{1}{3}\left(\frac{a-1}{a+1}\right)^3 + \tfrac{1}{5}\left(\frac{a-1}{a+1}\right)^{\frac{1}{5}} + \text{ \&c.} \right\}$$

$$4.\ \text{Log. } \frac{a}{b} = \frac{1}{M} \times \left\{ \left(\frac{a \backsim b}{b}\right) - \tfrac{1}{2}\left(\frac{a \backsim b}{b}\right)^2 + \tfrac{1}{3}\left(\frac{a \backsim b}{b}\right)^3 - \text{ \&c.} \right\}$$

$$5.\ \text{Log. } \frac{a}{b} = \frac{1}{M} \times \left\{ \left(\frac{a \backsim b}{a}\right) + \tfrac{1}{2}\left(\frac{a \backsim b}{a}\right)^2 + \tfrac{1}{3}\left(\frac{a \backsim b}{a}\right)^3 - \text{ \&c.} \right\}$$

$$6.\ \text{Log. } \frac{a}{b} = \frac{2}{M} \times \left\{ \left(\frac{a \backsim b}{a+b}\right) + \tfrac{1}{3}\left(\frac{a \backsim b}{a+b}\right)^3 + {}^{\frac{1}{5}}\left(\frac{a \backsim b}{a+b}\right)_{\frac{1}{5}} + \text{ \&c.} \right\}$$

$$7.\ \text{Log. } a = \text{log. } (a-1) + \frac{1}{M} \times \left\{ \frac{1}{a} + \frac{1}{2a^2} + \frac{1}{3a^3} + \frac{1}{4a^4} + \text{ \&c.} \right\}$$

$$8.\ \text{Log. } a = \text{log. } (a-1) + \frac{1}{M} \times \left\{ \frac{1}{a-1} - \frac{1}{2(a-1)^2} + \frac{1}{3(a-1)^3} - \text{ \&c.} \right\}$$

$$9.\ \text{Log. } a = \text{log. } (a-2) + \frac{2}{M} \times \left\{ \frac{1}{a-1} + \frac{1}{3(a-1)^3} + \frac{1}{5(a-1)^5} + \text{ \&c.} \right\}$$

To the above may be added the following, which will be found uſeful on many occaſions.

$$10.\ \text{Log. } a = \frac{1}{M} \times \left\{ (a - a^{-1}) - \tfrac{1}{2}(a^2 - a^{-2}) + \tfrac{1}{3}(a^2 - a^{-3}) - \text{ \&c.} \right\}$$

$$11.\ \text{Log. } (a+z) = \text{log. } a + \frac{1}{M} \times \left\{ \frac{z}{a} - \tfrac{1}{2}\frac{z^2}{a^2} + \tfrac{1}{3}\frac{z^3}{a^3} - \tfrac{1}{4}\frac{z^4}{a^4} + \text{ \&c.} \right\}$$

$$12.\ \text{Log. } (a-z) = \text{log. } a - \frac{1}{M} \times \left\{ \frac{z}{a} + \tfrac{1}{2}\frac{z^2}{a^2} + \tfrac{1}{3}\frac{z^3}{a^3} + \tfrac{1}{4}\frac{z^4}{a^4} + \text{ \&c.} \right\}$$

$$13.\ \text{Log. } (a \pm z) = \text{log. } a \pm \frac{2}{M} \times \left\{ \left(\frac{z}{a+z}\right) + \tfrac{1}{3}\left(\frac{z}{a+z}\right)^3 + \tfrac{1}{5}\left(\frac{z}{a+z}\right)^5 + \text{ \&c.} \right\}$$

$$14.\ \text{Log. } a = \frac{m}{M} \times \left\{ (\sqrt[m]{a} - 1) - \tfrac{1}{2}(\sqrt[m]{a} - 1)^2 + \tfrac{1}{3}(\sqrt[m]{a} - 1)^3 - \text{ \&c.} \right\}$$

Theſe formulæ might have been extended to a much greater length, but thoſe that are given will be found to embrace the generality of caſes, and will be found uſeful on various occaſions.

The publications on the ſubject of logarithms have been ſo numerous, that we can only find room to mention a ſmall portion of them, but as it is uſeful to know which are reputed the beſt, and particularly the beſt editions of the ſame authors, we ſhall ſubjoin the following enumeration, which may be conſidered as containing the moſt reſpectable and accurate works of this kind.

1. The firſt canon of logarithms for natural numbers from 1 to 20,000, and from 90,000 to 100,000, was conſtructed and publiſhed in 1624, by Briggs, with the approbation of the inventor lord Napier.

2. Briggs's logarithms, with their difference to 10 places of figures; as alſo the logarithmic ſines, tangents, &c. by George Miller, London 1631.

3. "Trigonometria," by Richard Norwood 1631, containing a table of logarithms from 1 to 10,000, beſides ſines, tangents, &c.

4. "Directorium Generale Uranometricum," by Francis Bonaventura Cavalerius, Bologna 1632. This work, beſide the uſual table of logarithms, contains ſeveral new and uſeful tables of ſines, verſed ſines, &c. and ſome other original matter.

5. In 1643 appeared the "Trigonometria" of the ſame author, which may alſo be conſidered an intereſting work.

6. "Tabulæ Logarithmicæ" by Nathaniel Rowe, London 1633. In this work the logarithms are given to eight places of figures, for every number from 1 to 100,000, and logarithmic ſines, tangents, &c. to every hundredth part of degrees to ten places.

7. "Trigonometria Britannica" by John Newton, London, 1658. Here the logarithmic tables are put in the moſt convenient form, being nearly the ſame as is now adopted by authors of the preſent period.

8. Adrian Vlacq alſo publiſhed different editions of logarithmic tables, which have been ſince republiſhed; theſe are generally conſidered very accurate and uſeful tables, particularly the edition of 1631.

9. Sherwins's mathematical tables, publiſhed in 8vo. London 1706, form the moſt complete collection of any we have yet noticed; containing, beſides the logarithms of all numbers from 1 to 100,000, the ſines, tangents, ſecants, and verſed ſines, both natural and logarithmic, to every minute of the quadrant. The firſt edition was printed in 1706, but the third, publiſhed in 1742, as reviſed by Gardiner, is conſidered as ſuperior to any other. The fifth, and laſt, edition publiſhed in 1717, is ſo incorrect, that no dependence can be placed upon it.

The third edition above-mentioned, which is called Gardiner's tables, was republiſhed at Avignon, in France, in 1770, but this is not conſidered ſo accurate as the original one by Gardiner himſelf.

10. An "Antilogarithmic Canon," for readily finding the number correſponding to any logarithm, was begun by the algebraiſt Harriot, and completed by Warner, the editor of the former's works, but it was never publiſhed for want of proper encouragement. But a complete canon of this kind was publiſhed by James Dodſon 1742, in which the numbers anſwering to each logarithm from 1 to 100,000, are computed to 11 places of figures.

11. In 1783 was publiſhed, by M. Callet, at Paris, a very neat and uſeful collection of logarithmic tables; and in 1795 an enlarged edition of the ſame work, under the title of "Tables Portative de Logarithms." This is an elegant work, beautifully printed and ſtereotyped, at the celebrated Didot's preſs; it is more correct than the former edition, though it contains a few errors not noticed in the liſt of errata.

12. Dr. Hutton's "Mathematical Tables," containing the common hyperbolic and logiſtic logarithms, alſo ſines, tangents, ſecants, and verſed ſines, both natural and logarithmic, together with ſeveral other tables uſeful in mathematical calculations. To which is prefixed a hiſtory of the diſcoveries and writings of the moſt celebrated authors on this ſubject. This work was firſt publiſhed in 1785, ſince which time it has paſſed through ſeveral editions, which are all very correct.

13. Taylor's tables of logarithmic ſines and tangents to every ſecond of the quadrant, to which is prefixed a table of logarithms from 1 to 100,000. This is a very valuable work, and has a uſeful introduction compoſed by the late aſtronomer royal Dr. Maſkelyne.

14. Vega's tables, publiſhed in Latin and German, is alſo a very excellent performance, particularly the ſecond edition of 1797.

15. Another very accurate and extenſive collection of tables, computed for the decimal diviſion of the circle by Borda, and revived and augmented by Delambre, was publiſhed in Paris. This work is held in great eſteem by the French; but it is of little uſe to Engliſh mathematicians on account of the particular diviſion of the circle. It is, however, preceded by a very perſpicuous and ſcientific inveſtigation of the moſt uſeful logarithmic ſeries, and trigonometrical formulæ; and may therefore be read with intereſt by the general mathematician. Beſides the authors above-mentioned, many others have treated on the ſubject of logarithms, among the principal of whom are Halley, Leibnitz, Mercator, Cotes, Brook Taylor, Euler, Maclaurin, Wolfius, Keill, and Simpſon.

As we have frequent occaſion to refer to tables of logarithms in the courſe of this work; we have ſubjoined a table of logarithms of all numbers from 1 to 10,000, which will be found uſeful in various caſes when other tables may not be at hand.

TABLE of Logarithms, from 1 to 10,000.

999	9995655	9996090	9996524	9996959	9997393	9997828	9998262	9998697	9999131	9999566	435

Deſcription and Uſe of the preceding Table.—In the above table are contained the logarithm of all numbers, from 1 to 10,000, which may be found by inſpection, according to the method deſcribed below; but it will be proper, before we enter upon that ſubject, to make a few remarks with regard to the index, or characteriſtic, of logarithms, which are omitted throughout, and muſt therefore be ſupplied by the operator, according as the caſe may require. It has been ſhewn that the baſe, or radix of the ſyſtem, is 10; and ſince

$$10^0 = 1,\ 10^1 = 10,\ 10^2 = 100,\ 10^3 = 1000, \ \&c.$$

therefore the log. of 1 = 0, the log. of 10 = 1, the log. of 100 = 2, the log. of 1000 = 3, &c.; and, conſequently, the logarithm of any number between 1 and 10 has its logarithm greater than 0, and leſs than 1; a number between 10 and 100 has its logarithm greater than 1, and leſs than 2; between 100 and 1000 the logarithm is greater than 2, and leſs than 3, and ſo on; therefore, the integral part of the logarithm, or its index, is always one leſs than the number of its integral places. Again, ſince

$$\frac{1}{10} = 10^{-1},\ \frac{1}{100} = 10^{-2},\ \frac{1}{1000} = 10^{-3},$$

it follows, that the logarithm of .1 = − 1, of .01 = − 2, of .001 = − 3, &c.; conſequently, the logarithm of a number between 1 and .1 has its index properly 0, and its decimal part negative; but for the greater convenience, and this is one great advantage attending Briggs's logarithms, we may aſſume the index negative, and the decimal part poſitive; that is, inſtead of ſubtracting the decimal part from unity, and making the reſult negative, we retain the decimal as it ariſes, and make the index negative: whence, the logarithm of a decimal greater than .1, has its index = − 1; if it be leſs than .1, but greater than .01, the index is − 2; if it be leſs than .01, but greater than .001, the index is − 3; and ſo on: whence it follows, that the index of the logarithm of any decimal is negative, and always one more than the number of ciphers which precede the firſt effective figure. Or both rules, *viz.* for integers and decimals, may be reduced to one, which is as follows. The index of the logarithm of any number is always equal to the number of places that the decimal point is diſtant from the unit's place, being poſitive if the decimal point be to the right of the unit's place, and negative if it be to the left of it. What has been ſaid will be illuſtrated by the following examples:

Numbers.	Logarithms.
34560.	4.5385737
3456.0	3.5385737
345.60	2.5385737
34.560	1.5385737
3.4560	0.5385737
.34560	−1.5385737
.034560	−2.5385737
.0034560	−3.5385737
.00034560	−4.5385737

Theſe examples will illuſtrate all that has been ſaid with regard to the index, and at the ſame time will ſhew the great advantage of the preſent ſyſtem of logarithms; for here the tabular part of the logarithm is the ſame throughout, whereas with any other radix, each of the numbers would have required a different logarithm; and, conſequently, much more extenſive tables than any of thoſe now in common uſe would be neceſſary under thoſe circumſtances.

To find the logarithm of any number by the table.—If the number conſiſts of leſs than three figures, annex a cipher to it, or two if neceſſary, conſidering it as a decimal, and look for the number thus increaſed in one of the firſt columns of the table, marked N, and the number in the adjacent column is the decimal part of the logarithm, to which prefix the proper index according to the above rule.

If the number conſiſts of three figures, it may be found immediately in one of the firſt columns, and its logarithm in the adjacent column, to which prefix the proper index as above.

If the number conſiſts of four figures, look for the firſt three in the column marked N, and ſeek the fourth figure in the line at the head of the page; and trace it down to the line in which the three firſt figures are found, and the meeting of the two lines will give the logarithm required; to which prefix the proper index. Thus,

The log. 34 = log. 34.0 = 1.5314789
The log. 6 = log. 6.00 = 0.7781513
log. 456 = 2.6589648
log. 4569 = 3.6590506
log. 45.69 = 1.6590506.

If the number conſiſts of more than four places, find the logarithm anſwering to the firſt four as above, and for the reſt multiply the number ſtanding in the correſponding column of difference, by the remaining figures of the propoſed number, and cut off from the right hand of the product as many figures as the multiplier conſiſts of, and add the other part of it to the right-hand figures of the logarithm before found; then prefix to that ſum the proper index, according to the rule above given. Thus, to find the logarithm of 34.6782;

$$\begin{array}{lrcr}
\text{log.} & 34.67 = 1.5391604 & \text{Diff.} = & 125 \\
 & 102 & & 82 \\
\cline{2-2}\cline{4-4}
\text{log.} & 34.6782 = 1.5391706 & & 250 \\
\cline{2-2}
 & & & 1000 \\
\cline{4-4}
 & & & 102(50 \\
\cline{4-4}
\end{array}$$

and in the ſame manner the logarithm of any number whatever may be found.

To find the number anſwering to any given logarithm by the table.—Seek for the decimal part of the logarithm in one of the columns of the table, and if it be found there *exactly*, the correſponding number is that required, the firſt three figures of which will be found in the column marked N, and the fourth in the head line of the table. Then point off the proper number of integers or decimals by the converſe of the rule given in the preceding article, *viz.* the unit's place muſt ſtand ſo many places to the right or left of the firſt figure, as is denoted by the index; to the right if that index be poſitive, and to the left if negative.

Thus, the natural number anſwering to the logarithms

2.5434472 is 349.5
−2.5434472 is 0.03495

when 9 in the firſt, and 0. in the ſecond, are made the places of units agreeably to the rule. But if the logarithm be not found exactly in the table, then ſeek the next greater and the next leſs, as alſo the difference between the leſs and the given logarithm, and between the leſs and the greater; which will be found in the correſponding column of difference; divide the former difference by the latter, and annex the quotient to the right-hand of the four figures before taken out, which will be the number required, remembering to point off the decimals according to the rule.—Note, The above quotient cannot be depended upon for more than two places.

Find the number correſponding to the logarithm
2.5430987.

Next greater log.	2.5431986	Given log.	2.5430987
Next leſs log.	2.5430742	Next leſs	2.5430742
Tabular differ.	1244	Differ.	245

1244)245.00(19
1244
12060
11196
.864

Therefore 349.219 is the number ſought, the firſt four figures being the number anſwering to the leaſt logarithm.

To perform arithmetical operation by logarithms.

Multiplication by logarithms.—Take out the logarithms of the factors from the table, and their ſum will be the logarithm of the product ſought; then, by means of the table, find the natural number anſwering to that logarithm, which will be the product required. Obſerving to add what is carried from the decimal part of the logarithm to the affirmative index, or indices, or ſubtract it from the negative. Alſo adding the indices together if they are of the ſame kind; *viz.* all poſitive, or all negative, but to ſubtract them if they be of different kinds, prefixing the ſign of the greater to the remainder. Thus,

Multiply together .7684, 68.42, and .34876
log. of .7684 = − 1.8855874
log. of 68.42 = 1.8351831
log. of .34876 = − 1.5425267
Product 18.3357 = 1.2632972

Diviſion by logarithms.—Here the logarithms are to be taken out as above, and then the logarithm of the diviſor muſt be ſubtracted from that of the dividend, and the remainder will be the logarithm of the quotient ſought, obſerving to change the ſign of the index of the diviſor from affirmative to negative, or from negative to affirmative; then take the ſum of the indices, if they be of the ſame kind, or ſubtract them if they be of different kinds, prefixing the ſign of the greater for the index. Alſo, if 1 is borrowed in the left-hand place of the decimal part of the logarithm, add it to the index of the diviſor when that index is affirmative, but ſubtract it when negative; then let the ſign be changed, and worked with as before. Thus, for example,

Divide 37.149 by 523.67
log. 37.149 = 1.5699471
log. 523.67 = 2.7190577
Quotient .0709397 = − 2.8508894

Involution, or raiſing of powers by logarithms.—Multiply the logarithm of the given number by the index of the power to which it is to be raiſed; and the product will be the logarithm of the power required. But in multiplying a logarithm with a negative index, the product will be negative, but what is carried from the decimal part will be poſitive, and muſt, therefore, in that caſe, be ſubtracted from that product.

Hence, to find the cube of .307146
log. of .307146 = − 1.4873449
3
Power .0289758 − 2.4620347

Evolution, or the extraction of roots by logarithms.—Divide the logarithm of the given number by the index of the power, the root of which is to be extracted, and the quotient will be the logarithm of the root required; obſerving, that if the index of the logarithm be negative, as many units muſt be borrowed as will make it exactly diviſible, and ſo many units muſt then be carried to the decimal part of the logarithm, and the diviſion carried on as uſual.

Required the cube root of .12345
log. 12345 3)−1.0914911
Root .497925 −1.6971637

Theſe are the moſt ſimple caſes in which logarithms are introduced into arithmetical operations; the application of them to more complex caſes, as in Trigonometry, Menſuration, &c. will be explained under the reſpective heads.

Logarithm, *Imaginary*, is uſed for the logarithm of negative and imaginary quantities, ſuch as $-a$, $\sqrt{-a}$, &c. Thus, alſo, the fluents of certain imaginary fluxionary expreſſions, ſuch as $\frac{\dot{x}}{x\sqrt{-1}}$, $\frac{a\dot{x}}{2bx\sqrt{-1}}$, &c. are imaginary logarithms. Euler Analyſ. Infin. vol. i. p. 72. 74.

The expreſſion $\frac{\dot{x}}{x}$ repreſents the fluxion of the logarithm of x, and the fluent, therefore, of $\frac{\dot{x}}{x}$ is the logarithm of x; but no logarithm can repreſent the fluent of $\frac{\dot{x}}{x\sqrt{-1}}$, which is therefore called an imaginary logarithm.

However, when theſe imaginary logarithms occur in the ſolutions of problems, they may be transformed into circular arcs or ſectors; that is, the imaginary logarithm, or imaginary hyperbolic ſector becomes a real circular ſector. See Bernouilii, Oper. tom. i. p. 400. and p. 512. Maclaurin's Fluxions, art. 762, ſeq. Walmeſly, Anal. des Meſ. p. 63.

LOGE, in *Geography*, a town of Germany, in the county of Hoya; 20 miles S.W. of Nienburg.

LOGGERHEAD Key, or *El Contoy*, a ſmall iſland in the bay of Honduras, near the coaſt of Yucatan. N. lat. 21° 25′. W. long. 87° 45′.

LOGGERHEAT, in the *Sea Language*, denotes a large round ball of iron, with a long handle for heating pitch.

LOG-HOUSES, houſes in America, which are generally the firſt that are erected on any new ſettlement, and which are cheaper than any others in a country where wood abounds. The ſides conſiſt of trees juſt ſquared, and placed horizontally one upon the other; the ends of the logs of one ſide reſting alternately on the ends of thoſe of the adjoining ſides, in notches; the interſtices between the logs are ſtopped with clay; and the roof is covered with boards or ſhingles, which are ſmall pieces of wood in the ſhape of ſlates or tiles, &c. which are uſed for that purpoſe, with few exceptions, throughout America. Theſe habitations are not very ſightly, but when well built they are warm and comfortable, and laſt for a long time. Some of them are built with brick or ſtone, or elſe conſtructed with wooden frames, ſheathed on the outſide with boards.

LOGIC, the art of thinking juſtly; or of making a right uſe of our rational faculties, in defining, dividing, and reaſoning: or, as it is defined by an excellent writer on this ſubject, logic is the art of uſing reaſon well in our enquiries after truth, and the communication of it to others. Watts.

The word is Greek, λογικη, derived from λογος, *ſermo*, *diſcourſe;* in regard thinking is only an inward, mental diſcourſe, wherein the mind converſes with itſelf.

Logic is alſo ſometimes called *dialectica;* and ſometimes the *canonical art*, as being a canon, or rule for directing us in our reaſonings.

As, in order to think aright, it is neceſſary that we apprehend, judge, diſcourſe, and diſpoſe, or methodize, rightly: hence perception or apprehenſion, judgment, diſcourſe or reaſoning, and diſpoſition, whence reſults method, become the four fundamental articles of this art; and it is from our reflections on thoſe operations of the mind that logic is, or ought to be, wholly drawn.

Lord Bacon divides logic into four branches, according to the ends propoſed in each: for a man reaſons, either to find what he ſeeks, or to judge of what he finds, or to retain what he judges, or to teach what he retains; whence ariſe ſo many arts of reaſoning; *viz.* the art of *inquiſition*, or invention; the art of *examining*, or judgment; the art of *preſerving*, or of memory; and the art of *elocution*, or delivery.

Logic, having being extremely abuſed, is now in ſome diſrepute. The ſchools have ſo clogged it with barbarous terms and phraſes, and have run it out ſo much into dry uſeleſs ſubtleties, that it ſeems rather intended to exerciſe the mind in wrangling and diſputation than to aſſiſt it in thinking juſtly. It is true, in its original, it was rather intended as the art of cavilling than of reaſoning; the Greeks, among whom it had its riſe, being a people who piqued themſelves mightily upon their being able to talk *extempore;* and to argue, by turns, on either ſide of the queſtion.—Hence their dialectici, to be always furniſhed with arms for ſuch rencontres, invented a ſet of words and terms, rather than rules and reaſons, fitted for the uſe of contention and diſpute.

Logic, then, was only an art of words, which frequently had no meaning, but ſerved well enough to hide ignorance inſtead of improving knowledge; to baffle reaſon inſtead of aſſiſting it; and to confound the truth inſtead of clearing it. Much of that heap of words, and rules, which we have borrowed from the old logic, is of little uſe in life; and is ſo far out of the common uſage, that the mind does not attend to them without trouble: and finding nothing in them to reward its attention, it ſoon diſcharges itſelf, and loſes all ideas it had conceived of them.

But logic, diſengaged from the jargon of the ſchools, and reduced into a clear and intelligible method, is the art of conducting the underſtanding in the knowledge of things, and the diſcovery of truth.

From its proper uſe we gain ſeveral very conſiderable advantages: for, 1. The conſideration of rules incites the mind to a cloſer attention and application in thinking: ſo that we hereby become aſſured, that we make the beſt uſe of our faculties. 2. We hereby more eaſily and accurately diſcover and find out the errors and defects in our reaſoning; for the common light of reaſon, unaſſiſted by logic, frequently obſerves an argumentation to be faulty, without being able to determine wherein the preciſe failure conſiſts. 3. By theſe reflections on the order and manner of the operations of the mind, we are brought to a more juſt and complete knowledge of the nature of our own underſtanding. See SOUL and UNDERSTANDING.

LOGICAL CONCRETE. See CONCRETE.

LOGICAL *Part*. See PART.

LOGINOV, in *Geography*, a town of Ruſſia, in the government of Tobolſk, on the Irtiſch; 16 miles S.E. of Tara.

LOGISTA, the title of an officer at Athens, whoſe buſineſs was to receive and paſs the accounts of magiſtrates when they came out of their office.

The logiſtæ were in number ten; they were elected by lot, and had ten euthyni, or auditors of accounts, under them.

LOGISTIC, or LOGARITHMIC *Line*, a curve ſo called, from its properties and uſes, in conſtructing and explaining the nature of logarithms.

If the right line AX (*Plate* XI. *Analyſis*, *fig.* 4.) be divided into any number of equal parts, and to the points of thoſe diviſions, A, P, p, &c. be drawn lines continually proportional, the points N, M, m, &c. form the logiſtic or logarithmic line or curve.

Here the abſciſſas AP, Ap, &c. are the logarithms of the ſemiordinates PM, pm, &c.

Hence, if $AP = x$, $Ap = v$, $PM = y$, $pm = z$, and the logarithms of y and $z = ly$ and lz; x will be $= ly$, and $v = lz$; conſequently $x : v = ly : lz$; that is, the denominators of the ratios $AN : PM$, and $AN : pm$, are to one another as the abſciſſas AP and Ap.

Hence it follows, that there may be infinite other logiſtic lines invented: provided $xm : vm :: ly : lz$, that any of the roots, or powers, may be the logarithms of the ſemiordinates. The logiſtic will never concur with the axis, except at an infinite diſtance; ſo that AX is its aſymptote. See LOGARITHMIC *Curve*.

LOGISTIC, *Quadrature of the*. See QUADRATURE.

LOGISTIC, or *Logarithmic ſpiral*, a line whoſe conſtruction is as follows: Divide the quadrant of a circle into any number of equal parts, in the points N, n, n, &c. (*Plate* XI. *Analyſis*, *fig.* 5.) and from the radii CN, Cn, Cn, &c. cut off CM, Cm, Cm, &c. continually proportional, the points M, m, m, &c. form the logiſtic ſpiral.

The arcs, therefore, AN, An, &c. are the logarithms of the ordinates CM, Cm, &c. whence alſo it follows, that there may be infinite logiſtic ſpirals. See SPIRAL.

LOGISTICA, or LOGISTICAL *Arithmetic*, a denomination ſometimes given to the arithmetic of ſexageſimal fractions, uſed by aſtronomers in their calculations.

It was ſo called from a Greek Treatiſe of one Barlaamus Monachus, who wrote about ſexageſimal multiplication very accurately; and intitled his book Λογιστικη. This author Voſſius places about the year 1350, but he miſtakes the work for a treatiſe of Algebra.

Shakerly, in his Tabulæ Britannicæ, has a table of logarithms adapted to the ſexageſimal fractions; which, therefore, he calls logiſtical logarithms; and the expeditious arithmetic of them, which is by this means obtained, and by which all the trouble of multiplication and diviſion is ſaved, he calls logiſtical arithmetic.

LOGOGRAPHI, Λογογραφοι, among the *Ancients*, were the ſecretaries of the logiſtæ, and kept an account of the public revenues.

LOGOGRAPHY, derived from λογος, *word*, and γραφω, *I write*, a new mode of printing, in which the types correſpond to whole words, and not, according to the uſual method, to ſingle letters. For this mode of printing a patent was obtained ſome years ago, and in the year 1785 the origin and utility of the art were ſtated in a treatiſe written by Henry Johnſon. From the year 1778 he made ſeveral ſucceſsful attempts for the practice of this art. The author has undertaken to demonſtrate ſeveral advantages belonging to this method of printing; *viz.* 1. That the compoſitor ſhall have leſs charged upon his memory than in the common way. 2. That it is much leſs liable to error. 3. That the type of each word is as eaſily laid hold of as that of a ſingle letter. 4. That the decompoſition is much more readily performed, even by novices, than that of mere letters. 5. That no extraordinary expence nor greater number of types is required in the logographic than in the common method of printing. For other particulars, we muſt refer to the author's own account of the invention. See STEREOGRAPHY.

LOGOGRIPHUS, from the Greek λογος, *diſcourſe*, and γριφος, or γριπος, *net*, a kind of ſymbol, or riddle, propoſed to ſtudents for their ſolution, in order to exerciſe and improve the mind.

The logogriphus uſually conſiſts in ſome equivocal alluſion, or mutilation of words; which, literally taken, ſignify ſomething different from the thing intended by it; ſo that it is a kind of medium between a rebus and proper enigma.

According to Kircher, logogriphi are a kind of canting arms: thus a perſon called Leonard, who bore in his arms a lion and nard, or ſpikenard, according to that father, made a logogriphe. Œdip. Ægypt.

In another place, the ſame author defines logogriphus to be an enigma; which, under one name or word, will bear various meanings, by adding or retrenching ſome part of it. This kind of enigmas is well known to the Arabs; among whom are authors who treat expreſsly of it.

LOGONE, in *Geography*, a town of Hindooſtan, in Viſiapour; 10 miles N. of Poonah.

LOGONI, a town of Sardinia; nine miles E. of Cagliari.

LOGORAS, a town of Syria; 15 miles N. of Antioch.
